DUCLOS, CHARLES PINEAU (1704–1772), a French author, was born at Dinant, in Brittany, in 1704. At an early age he was sent to study at Paris. After some time spent in dissipation he began to cultivate the society of the wits of the time, and became a member of that club or association of young men who published their joint efforts in light literature under the titles of *Recueil de ces Messieurs*, *Étrennes de la St Jean*, *Œufs de Pâques*, &c. His romance of *Acajou and Zirphile*, which was composed after a series of plates which had been engraved for another work, was one of the fruits of this association, and was produced in consequence of a sort of wager amongst its members. Duclos had previously written two other romances, which were more favourably received—*The Baroness de Luz*, and *The Confessions of the Count de ****. His first serious publication was the *History of Louis XI.*, which is dry and epigrammatical in style, but displays considerable powers of research and impartiality. The reputation of Duclos as an author was confirmed by the publication of his *Considérations sur les Mœurs*, a work which is much and justly praised by Laharpe, as containing a great deal of sound and ingenious reflection. It was translated into English and German. The *Mémoires pour servir à l'Histoire du dix-huitième Siècle*, which were intended by the author as a sort of sequel to the preceding work, are nevertheless much inferior in respect of both style and matter, and are, in reality, little better than a kind of romance. In consequence of his *History of Louis XI.*, he was appointed historiographer of France, when that place became vacant on Voltaire's retirement to Prussia. His *Secret Memoirs of the reigns of Louis XIV. and Louis XV.*, and his *Considerations on Italy*, were not published until after the Revolution. The former work is highly spoken of by Chamfort. Duclos became a member of the Academy of Inscriptions in 1739, and of the French Academy in 1747. Of the latter he was appointed perpetual secretary in 1755. Both academies were indebted to him not only for many valuable contributions, but also for several useful regulations and improvements. As a member of the Academy of Inscriptions, he composed several memoirs on the Druids, on the origin and revolutions of the Celtic and French languages, on trial by battle and proof by ordeal, and on scenic representations and the ancient drama. As a member of the French Academy, he assisted in compiling the new edition of the *Dictionary*, which was published in 1762; and he made some just and philosophical remarks on the

Port Royal Grammar. On several occasions he distinguished himself by vindicating the honour and prerogatives of the societies to which he belonged, and the dignity of the literary character in general. He used to say of himself, "I shall leave behind me a name dear to literary men." The citizens of Dinant, whose interests he always supported with zeal, appointed him mayor of their town in 1744, though he was resident at Paris. He was afterwards elected deputy from the commons to the assembly of the states of Brittany, and upon the requisition of this body the king granted him letters of nobility. In 1766 he was advised to retire from France for some time, having rendered himself obnoxious to the Government by the opinions he had expressed on the dispute between the Duc d'Aiguillon and M. de la Chalotais, the friend and countryman of Duclos. Accordingly he set out for Italy; and on his return he wrote an account of his travels, which is also praised by Chamfort. He died at Paris, March 26, 1772, in the sixty-ninth year of his age. The character of Duclos was singular in its union of impulsiveness and prudence. Rousseau described him very laconically as a man *droit et adroit*. In his manners he displayed a sort of bluntness in society, which frequently rendered him disagreeable; and his caustic wit on many occasions created enemies. To those who knew him, however, he was a pleasant companion. A considerable number of his *bon mots* have been preserved by his biographers. A complete edition of the works of Duclos, including an unfinished autobiography, was published by Desessarts, at Paris, in 10 vols. 8vo, 1806.

DUDEVANT, ARMANTINE LUCILE AURORE (1804–1876), known to all the world as the second, if not the greatest, of French novelists, by her assumed name of George Sand, was born at Paris 5th July 1804, and died 8th June 1876. Her life is as fantastic and eventful as any of her fictions, and the main secret of her success has been her power to clothe in artistic form her varied experiences of men and places.

It is no easy task to set down in a short space the outward events of her life, and to trace the development of her genius, not only because of the abundance of materials she has left behind her, but still more from the subtle way in which she has interwoven fact and fiction. In the *History of her Life*, which covers half a century, the omissions are no less surprising than the revelations, and though she never indulges in the self-illusions of *Dichtung und Wahrheit*, which perplex or mystify the biographers of Goethe, yet she wisely refuses to satisfy the curiosity of the public on the most delicate episodes of her life. If, to fill up the blanks, we turn to her novels, George Sand justly warns us that in trying to raise the mask and identify her with any one of her characters, we shall not only lose our pains, but show that we mistake the fundamental conditions of art. Yet by the help of critics to supply the missing clue (and no writer of this century has so provoked criticism), it is possible to decipher the chief lineaments of the most remarkable woman of this age, and the greatest authoress in the world's history.

Aurore was the daughter of Lieutenant Dupin and of his newly-married mistress Sophie Delaborde, the daughter of a Paris bird-fancier. Her paternal grandfather was M. Dupin de Francueil, a farmer-general of the revenue, who had married Mdlle. Rintean, widow of Comte Horn (a natural son of Louis XV.), and natural daughter of Marshal Saxe, the most famous of the many illegitimate children of Augustus the Strong by the lovely countess of Konigsmarck. This strange pedigree has been traced in detail by George Sand, and she recognizes it as one of the elements which went to mould her character. She boasts of the royal blood which she inherited through her father, and, disregarding the bar sinister, claims relationship with Charles X.

and Louis XVIII, and she proclaims herself as frankly a daughter of the people, endowed by nature with the instincts of her class. Her birth itself was romantic. Her father was playing a country dance at the house of a fellow officer, the future husband of Sophie's sister, when he was told that his wife, who had not long left the room, had borne him a daughter. "She will be fortunate," said the aunt, "she was born among the roses to the sound of music."

Passing by her infantine recollections, which go back further than even those of Dickens, we find her at the age of three crossing the Pyrennees to join her father who was on Murat's staff, occupying with her parents a suite of rooms in the royal palace, adopted as the child of the regiment, nursed by rough old sergeants, and dressed in a complete suit of uniform to please the general.

For the next ten years she lived at Nohant, near Le Châtre in Berry, the country house of her grandmother. Here her character was shaped; here she imbibed that passionate love of country scenes and country life which neither absence, politics, nor dissipation could uproot; here she learnt to understand the ways and thoughts of the peasants, and laid up that rich store of scenes and characters which a marvellously retentive memory enabled her to draw upon at will. The progress of her mind during these early years well deserves to be recorded. Education, in the strict sense of the word, she had none. A few months after her return from Spain her father was killed by a fall from his horse. He was a man of remarkable literary gifts as well as a good soldier, and his letters, which are included in her life, show in a less degree the vivid force of description and clear insight into character which he bequeathed to his daughter. "Character," says George Sand, "is in a great measure hereditary: if my readers wish to know me they must know my father." On his death the mother resigned, though not without a struggle, the care of Aurora to her grandmother, Mme Dupin de Francueil, a good representative of the *ancien régime*. Though her husband was a patron of Rousseau, she herself had narrowly escaped the guillotine, and had only half-imbibed the ideas of the Revolution. In her son's lifetime she had, for his sake, condoned the *mésalliance*, but it was impossible for the stately châtelaine and her low-born daughter-in-law to live in peace under the same roof. She was jealous as a lover of the child's affection, and the struggle between the mother and grandmother was one of the bitterest of Aurora's childish troubles.

Next to the grandmother, the most important person in the household at Nohant was Deschatre. He was an ex-abbé who had shown his devotion to his mistress when her life was threatened, and henceforward was installed at Nohant as factotum. He was maire of the village, he managed the estate, doctored the neighbourhood, played picquet with Madame, was tutor to Aurora's half-brother, and, in addition to his other duties, undertook the education of the girl. The tutor was no more eager to teach than the pupil to learn. He, too, was a disciple of Rousseau, believed in the education of nature, and allowed his Émile to wander at her own sweet will. At odd hours of lessons she picked up a smattering of Latin, music, and natural science, but most days were holidays and spent in country rambles and games with village children. Yet even then, though she passed for an ordinary child, somewhat more wayward and less instructed than the average, her special powers had begun to show themselves. Her favourite books were Tasso, *Atala*, and *Paul et Virginie*. A simple refrain of a childish song or the monotonous chaunt of the ploughman touched a hidden chord and thrilled her to tears. Like Blake she fell into involuntary trances, saw visions and heard voices, though, unlike Blake, she never mistook

her day-dreams for realities. She invented a deity of her own, a mysterious Corambé, half pagan and half Christian, and like Goethe erected to him a rustic altar of the greenest grass, the softest moss, and the brightest pebbles.

From the free out-door life at Nohant she passed at thirteen to the convent of the English Augustinians at Paris, where for the first two years she never went outside the walls. Nothing better shows the plasticity of her character than the ease with which she adapted herself to this sudden change. The volume which describes her conventual life is as graphic as Miss Brontë's *Villette*, but we can only dwell on one passage of it. Tired of mad pranks, in a fit of home-sickness, she found herself one evening in the convent chapel. In a strange reverie she sat through vespers. Time passed unnoticed, the prayers were over, the chapel was being closed.

"I had forgotten all, I knew not what was passing in me; with my soul rather than my senses, I breathed an air of ineffable sweetness. All at once a sudden shock passed through my whole being, my eyes swam, and I seemed wrapped in a dazzling white mist. I heard a voice murmur in my ear, 'Tolle, lege.' I turned round thinking that it was one of the sisters talking to me—I was alone. I indulged in no vain illusion, I believed in no miracle, I was quite sensible of the sort of hallucination into which I had fallen; I neither sought to intensify it nor to escape from it. Only I felt that faith was laying hold of me—by the heart, as I had wished it. I was so filled with gratitude and joy that the tears rolled down my cheeks. I felt as before that I loved God, that my mind embraced and accepted that ideal of justice, tenderness, and holiness which I had never doubted, but with which I had never held direct communion, and now at last I felt that this communion was consummated, as though an invincible barrier had been broken down between the source of infinite light and the smouldering fire of my heart. An endless vista stretched before me, and I panted to start upon my way. There was no more doubt or lukewarmness. That I should repent on the morrow and rally myself on my over-wrought ecstasy never once entered my thoughts. I was like one who never casts a look behind, who hesitates before some Rubicon to be crossed, but having touched the further bank sees no more the shore he has just left."

Such is the story of her conversion as told by herself. It reads more like a chapter from the life of *Sté Thérèse* or *Madame Gnyon* than of the author of *Lélie*. Yet no one can doubt the sincerity of her narrative, or even the permanence of her religious feelings under all her many phases of faith and aberrations of conduct. A recent critic has sought in religion the clue to her character and the mainspring of her genius. But, except we take religion in the vague sense of the vision and the faculty divine, this is a one-sided view. "Half poet and half mystic" is the verdict she pronounces on herself, and we may add that her element of mysticism was always subordinate to the poetic. "Je fus toujours tourmentée des choses divines," ever stirred and stimulated, but never possessed by things divine.

Again in 1820 Aurora exchanged the restraint of a convent for freedom, being recalled to Nohant by Mme. de Francueil, who had no intention of letting her granddaughter grow up a *dévoté*. She rode across country with her brother, she went out shooting with Deschatre, she sat by the cottage doors on the long summer evenings and heard the flax-dressers tell their tales of witches and warlocks. She read widely though unsystematically Aristotle, Leibnitz, Locke, Condillac, and fed her imagination with *René* and *Childe Harold*. Her confessor lent her the *Genius of Christianity*, and to this book she ascribes the first change in her religious views. She renounced once for all the asceticism and isolation of the *De Imitatione* for the more genial and sympathetic Christianity of Chateaubriand. Yet she still clung to old associations, and on her grandmother's death was about to return to her convent, but was dissuaded by her friends, who found her a husband in the person of M. Dudevant, a retired officer who had turned farmer. About her husband and her married life George Sand is discreetly reticent. It was a marriage, if not of love, yet

of inclination, and the first years of her married life, during which her son and daughter, Maurice and Solange, were born, were at least calm and peaceful. Soon differences arose. Her husband seems to have been neither better nor worse than the Berrichon squires around him; but she found herself mated, if not to a clown, yet to a *hobereau* whose heart was in his farm and cattle. After nine years of passive endurance she determined to put an end to a connection which had grown intolerable, and in 1831 an amicable separation was agreed upon. Nohant was surrendered to the husband, and, taking her daughter with her, she went to seek her fortune in Paris with no provision but an allowance of £60 a year. After vain attempts to support herself by some of those expedients to which reduced gentlewomen are driven, as a last resource she tried literature. At this period she was living in a garret, often unable to afford the luxury of a fire. Repulsed by Balzac and Kératry, she found an employer in Delatouche, the editor of *Figaro*, and, like herself, a native of Berri. In her life she has done full justice to the rough honesty and jealous affection of her first critic, who treated her much as Dr Johnson treated Fanny Burney. George Sand had neither the wit nor the piquancy to succeed as a writer in *Figaro*, and at the end of a month her earnings amounted to fifteen francs. But there was on the same staff a young law student already known to her as a visitor at Nohant. With Jules Sandeau she entered into literary partnership, and under the name of Jules Sand there appeared a novel, their joint work, called *Rose et Blanche*. Her second novel was written independently, and the famous pseudonym, George Sand, was a compromise between Madame Dudevant, who wished to preserve the joint authorship, and Jules Sandeau, who disclaimed any share in the work. Nothing like *Indiana* had appeared before in French fiction. The public were wearied with the unreality of the fashionable historical novel, and the realistic humour of Paul de Kock. Balzac's earliest novels gave little promise of his future greatness. In the unknown writer they found one who combined the absorbing passion of Rousseau, the delicate picturesqueness of St Pierre, and the wild grandeur of Chateaubriand, in a living picture of present times and manners. Like Byron she awoke one morning and found herself famous. Delatouche was the first to throw himself at her feet and bid her forget all the hard things he had said of her. Sainte-Beuve expressed the approval of the learned, and the public eagerly canvassed the secret of her name, sex, and history. *Valentine*, which appeared two months afterwards, proved that *Indiana* was not, like so many first novels, a graphic rescript merely of the author's own emotions, but the beginning of an inexhaustible series, in which experience was the raw material woven by imagination and coloured by fancy. In *Valentine*, written during a visit to Nohant, she draws her inspiration from her native soil, and nowhere has she better described the quiet beauty and pastoral melancholy of the Vallée Noire and the banks of the Indre. Her Bohemian life at Paris—her *vie de gamin*, as she calls it—in which she adopted not only the dress but the life of a college student, and made the acquaintance of the whole Paris world between the artist and the artisan, is sketched by her in an allegory which is worth quoting if only as a specimen of the simple perfection of her style.

"I care little about growing old; I care far more not to grow old alone, but I have never met the being with whom I could have chosen to live and die, or if I ever met him I knew not how to keep him. I listen to a story and weep. There was a good artist called Watelet, the best aquafortis engraver of his day. He loved Marguerite Lecomte, and taught her to engrave as well as himself. She left husband and home to go and live with him. The world condemned them, then, as they were poor and modest, it forgot them. Forty years afterwards their retreat was discovered. In a cottage in the environs of Paris called *le moulin joli*, there sat at the same table an old man engraving and an old woman whom he called

his *meunière* also engraving. The last design they were at work upon represented the *Moulin joli*, the house of Marguerite, with the device *Cur ralle permutem Sabina divitiis operosioris*. It hangs in my room over a portrait the original of which no one here has seen. For a year the person who gave me this portrait sat with me every night at a little table and lived by the same work. At daybreak we consulted together on our work for the day, and at night we supped at the same little table, chatting the while on art, on sentiment, on the future. The future broke faith with us. Pray for me, O Marguerite Lecomte!"

Her third novel, *Lélie*, marks the climax of her rebellion against society. It was written in a fit of deep depression, religious and political, and is a wild dithyramb, the passionate wail of a woman whose affections have been blighted, and whose jaundiced eyes see nothing but a lifeless, loveless, godless world. But like Goethe in his *Werther* she "rid her bosom of that perilous stuff," and, though once and again she inveighed against society, she never more lost faith in the moral government of the world.

Of her unfortunate relations with A. de Musset, and her voyage to Italy in his company, which followed the publication of *Lélie*, nothing need be said except as they affected her literary career. As the motives of *Indiana* and *Valentine* are an unhappy marriage, so the novels of this period (1833–1835), *Jacques*, *André*, and *Leone Leon*, are the outcome of an unhappy liaison. Her creed, the opposite of Shakespeare's, is, that love must alter as it alteration finds, and that no ties are binding but the mutual passion of the hour. *Elle et lui* is a woman's version of the quarrel between a man and woman, and if true it ought never to have been told. The moral of the tale is worth giving in George Sand's own words, "God makes certain men of genius to wander in the tempest and to create in pain. I studied you in your light and in your darkness, and know that you are not to be weighed in the balance like other men." The measure she here metes to De Musset we may fairly measure to her again.

To this Italian journey we owe some of her most charming pictures of scenery. Venice was the only town she loved for itself, and it exercised over her the same fascination as over Byron, Shelley, and Goethe. The opening scenes of *Consuelo* are worthy to take rank with "Otway, Redcliffe, Schiller, Shakespeare's Art," with the 4th canto of *Clude Harold*, Shelley's *Lyrics*, and Goethe's *Venetian Epigrams*. The *Lettres d'un Voyageur* mark the calm which succeeded this Sturm und Drang period. They are specially valuable to the student of George Sand, as they give her views of men and things, not refracted and distorted by the exigencies of a novel. In *Michel de Bourges* (the "Edouard" of the letters) we make the acquaintance of another of those celebrated men who influenced for a time her life and writings. He conducted the suit which ended in a judicial separation from her husband (1836), and sought to convert her to the extreme republicanism of which he was the foremost advocate and defender. This Lovelace of politics laid siege to her intellect as persistently as Richardson's hero (for nine mortal hours he declaimed to her, pacing to and fro before her hotel at Bourges, and at Paris he locked her into her own room that she might reflect at leisure on his suit), but though she coquetted with his communistic theories, her artist nature rebelled against his extravagant radicalism. She sought safety in flight, but *Mauprat*, which she published this year, bears marks of his influence. The *Lettres à Marcie*, of 1837, are a tribute to the broad and noble Catholicism of Lamennais, and an eloquent exposition of the doctrine of Christian resignation; but in *Spiridon* (1838) she returns to her proper creed, a philosophical theism founded on sentiment and unfettered by dogma. *Consuelo* (1841) and *Lucretia Floriani* (1847) were inspired by Chopin, whose declining health she tended for more than six years with motherly care. *Le Compagnon du Tour de France* (1840) and *Le meunier*

d'Angibault (1845) are echoes of the socialism of Pierre Leroux. She threw herself heart and soul into the republican struggle of 1848, composed manifestoes for her friends, addressed letters to the people, and even started a newspaper. But her political ardour was short-lived; she cared little about forms of government, and, when the days of June dashed to the ground her hopes of social regeneration, she quitted once for all the field of politics and returned to her quiet country ways and her true vocation as an interpreter of nature, a spiritualizer of the commonest sights of earth and the homeliest household affections. In 1849 she writes from Berri to a political friend,—“You thought that I was drinking blood from the skulls of aristocrats. No, I am studying Virgil and learning Latin!”

To a youth of storm and stress succeeded an old age so calm and happy that it has no history. For more than a quarter of a century she continued year by year to gladden the world by some new creation, and the last of her works, the posthumous *Contes d'une Grand'mère*, is as fresh and vigorous and far more beautiful than *Indiana*. Only once was the serenity of her life troubled. The *Journal of a Traveller during the War* will be quoted by future historians not only as a record of that agonizing crisis through which the French nation passed, but also as a prophecy of its recovery, which, by the indomitable spirit it expressed, brought its own fulfilment.

In writing the life of Madame Dudevant we have glanced at some of the most important of her works. To chronicle the titles only of all her novels would require an Homeric catalogue. It is only possible to give a general estimate of her style and of her place in French literature. But first we must call attention to her latest group of novels, which we omitted in the life as deserving a separate notice. With *Jeanne* (1852) began that series of pastorals, or stories of village life, by which George Sand is best known to the English public, and by which, we believe, she will be longest remembered. No description is needed of works so well known as *La petite Fadette*, *La mare au diable*, *Les Matres Sonneurs*, *Le meunier d'Angibault*, *Nanon*, and *François le Champi*. With these may be classed the fairy-stories which she wrote for her grandchildren in the last years of her life, *Le géant Yéous*, *La reine Coax*, *Le nuage rose*, *Les ailes de courage*. They are too recent to be much known in England, but we may safely predict that they will be as familiar to our grandchildren as *La petite Fadette* is to us. Without attempting to analyze, we may shortly indicate the peculiar charm and originality of her idyllic novels.

1. Like Wordsworth, with the inward eye she sees into the life of things; she seizes with her pencil the visionary gleam; she shows the mystical influences which emanate from the world of sense, the witchery of the sky, the quiet soul of the river, the beauty born of murmuring sound, the gray *landes* stretching far away to the blue horizon, the deep-meadowed champaigns with orchard lawns and bowery hollows.

2. Like Wordsworth, too, she had found love in huts where poor men dwell, and like him she is “a leader in that greatest movement of modern times, care for our humbler brethren,—her part being to make us reverence them for what they are, what they have in common with us, or in greater measure than ourselves.”

3. To interpret for her readers these pictures of primitive life she has invented a style of her own,—not that, like Fontenelle, she makes her shepherds talk the language of the court, but she expresses the feelings of peasants in words so simple that a peasant might have used them, and yet so pure that they would pass muster with the Académie. Like Courier she is archaic, but her archaisms are not extracted from books, but relics of classical French which still lingered on in the quiet nooks of central France.

In conclusion, a few words must be said of her style, though much of its delicate harmony must elude a foreign critic, for it is by her style that she will chiefly live. It is simple and unaffected, yet full of subtle turns and picturesque expressions. Her dialogue is sparkling, her narrative clear and flowing, her descriptions exact, and her eloquence grandiose yet never meretricious. Topin is reminded of “the language of Rousseau, with something more of ease and finesse, the grace of Bernadin St Pierre, without his over-refinement, the warmth and eloquence of our greatest orators, and that without effort or straining.” Nisard pronounces George Sand the master of French prose writers. To Thackeray her diction recalled the sound of country bells falling sweetly and sadly on the ear; it stirred the nerves of Mill like a symphony of Haydn or Mozart.

One of the greatest of English novelists seems by the name she has adopted to provoke comparison with George Sand. In psychological analysis and insight into the problems of modern life, she is at least her equal; in her range of knowledge, in self-control, and in practical common sense, she is greatly her superior; but in unity of design, in harmony of treatment, in that purity and simplicity of language so felicitous and yet so unstudied, in all those qualities which make the best of George Sand's novels master pieces of art, she is as much her inferior. George Eliot is a great moralist, a great teacher; George Sand, whatever we may think of her doctrine and her morality, is by universal consent a supreme artist.

She has stayed in many camps, and lent her pen to many causes, she has had many friends and many lovers, but to one cause only has she remained constant—the cause of human progress; and the only master in whose service she has never wearied is art. (F. S.)

DUDLEY, a parliamentary and municipal borough of England, in a detached portion of the county of Worcestershire surrounded by the county of Stafford. It lies in the centre of the “Black Country,” about eight miles W.N.W. of Birmingham, at a junction on the Great Western railway. The town is generally well-built, its streets are well-paved, and there is a fair supply of water. The principal buildings are the parish church of St Thomas, rebuilt in 1819 at a cost of £23,000, and restored in 1862; several other churches, of which the most recent is St Luke's, erected in 1876; the town-hall, the county court, the Guest hospital (formerly the blind asylum), endowed (1868) by Joseph Guest, with a legacy of £20,000 (1861), the school of art, the new dispensary (1868), and the mechanics' institute (1861). Among the educational establishments are a free grammar-school, a subscription library, and a geological society with a small scientific museum. On a hill to the north are the extensive remains of an ancient castle, surrounded by beautiful grounds; and in the market-place stands a fountain, erected by the earl of Dudley at a cost of £3000, on the occasion of his marriage. The presence of coal, iron-ore, and limestone gives its peculiar character to the industries of the place. According to the census of 1871, 5442 men were engaged in the iron manufacture, 1040 as makers of engines or machines, and 3501 in the coal-mines; while the nail manufacture alone gave employment to 1267 males and 3019 females. Among the various articles produced are fire-irons, stoves, shovels, edge tools, chains, anchors, and especially anvils and vices. The glass-works, brass foundries, and brickworks are also of importance; and tanning, brewing, and malting are extensively carried on. The parliamentary borough has an area of 7715 acres, and returns one member to Parliament. In 1871 the population of the municipal borough, which has an area of 3680 acres, was 43,782; that of the parliamentary borough was 82,249.

Dudley castle, according to an unfounded tradition preserved by Camden, was first built about 700 by a Mercian prince called Dodo. It is mentioned in Domesday book as belonging after the conquest to William Fitz Ansculf. Being held in 1138 for the empress Matilda by Ralph Paganel, it was burnt by Stephen. In 1161 Gerrase, Ralph's son, founded a priory for Clunian monks, about a quarter of a mile to the west of the castle, at a spot still distinguished by a few ruins. The lordship was afterwards held by the Somers, and the Suttons; and from the latter family it was transferred by marriage to the Wards of Bixley. John Ward, sixth Baron Dudley, was in 1768 created Viscount Dudley and Ward, and in 1827 John William, the fourth viscount, was created Earl Dudley. The title died with him in 1833, but was restored in 1860 in favour of William, his second cousin. The description Sir Amyas Pawlet gives of the town in 1585 is—"one of the poorest towns I have seen in my life." On its surrender to the Parliament in 1646-7 the fortifications of the castle were demolished, but it continued habitable to 1750, when a fire broke out which reduced it to its present ruinous state. Dudley was enfranchised in 1832 by 2 Will. IV. c. 45; and it received incorporation in 1865. See *Booker's History of Dudley*, and *Twamley's History of Dudley Castle and Priory*, 1867.

DUDLEY, EARLS OF. See NORTHUMBERLAND.

DUEL, a deadly combat between two persons. The word is used in two distinct senses—(1) the judicial combat, a form of trial which prevailed in the Middle Ages, ordained by law as a proof of guilt or innocence; and (2) the modern duel, a pre-arranged combat with deadly weapons between two private persons to settle some private quarrel.

Though duelling is in England obsolete, and in other countries fast obsolescent, yet it must still command our attention as the latest survival of feudalism, and its history will always be studied as one of the most curious developments of mediæval society.

On the origin of the duel a vast amount of perverse ingenuity has been spent. Writers of the 16th and 17th centuries commonly begin their treatises with an account of the combats between David and Goliath, Hector and Achilles, the Horatii and Curiatii. By etymology it is true that *duellum* is the same word as *bellum*, and in this sense the origin of the duel must be traced to the earliest condition of society, when every man's hand was against his neighbour. But, in the specialized sense which the word now bears, the duel was a peculiar institution of comparatively recent origin, a local custom which never spread beyond the limits of civilized Europe. It is easily distinguished both from the casual affrays of savages and the set battles of the champions of contending nations. An account of the judicial duel will clearly show that it is the direct parent of the modern duel. In the year 501 Gondebald, king of the Burgundians, passed a law authorizing the wager of battle, and in the preamble he gives his reason for introducing this new form of trial. It is that his subjects may no longer take oaths upon uncertain matters, or forswear themselves upon certain. Here is one proof among many that the judicial duel was introduced to correct the abuses of compurgation by oath. Like the other ordeals which it superseded, it was a direct appeal to Heaven to vindicate truth and punish falsehood. Like them it was founded on the superstitious spirit of the age, but unlike them it addressed itself to the martial temper and personal prowess of the nobles. Other ordeals, such as the cross, the corsned, and the oath on the gospels, were in the hands of the clergy, and were manipulated by them in the interest of the church or of themselves. In the wager of battle each man felt that his cause was in his own hands, and, though might was right, yet even this was better than the jugglery of priests. Nor, as Montesquieu has pointed out, was the trial so irrational as it would seem to modern eyes. Among a warlike people cowardice is a sign of other vices, vices which are most hateful and most prejudicial to a simple community, of meanness, lying, and fraud. It shows an indifference to public opinion, a neglect

of the education of the day, which consisted mainly in the use of arms and warlike exercises. In a word, the law was neither better nor worse than the received morality of the time. From this jurisdiction none was exempt; women, minors, and ecclesiastics were required to appear by proxy; and adverse witnesses, and even the judge himself, were liable to be challenged to make good their words by force of arms. Those who are curious to observe the formalities and legal rules of a judicial combat will find them described at length in the 28th book of Montesquieu's *Esprit des Loix*. On these regulations he well remarks that, as there are an infinity of wise things conducted in a very foolish manner, so there are some foolish things conducted in a very wise manner. For our present purpose it is sufficient to observe the development of the idea of personal honour from which the modern duel directly sprang. In the ancient laws of the Swedes we find that if any man shall say to another, "You are not a man equal to other men," or "You have not the heart of a man," and the other shall reply, "I am a man as good as you," they shall meet on the highway, and then follow the regulations for the combat. What is this but the modern challenge? By the law of the Lombards if one man call another *arga*, the insulted party might defy the other to mortal combat. What is *arga* but the *dukker Junger* of the German student? Beaumanoir thus describes a legal process under Louis le Débonnaire:—The appellant begins by a declaration before the judge that the appellee is guilty of a certain crime; if the appellee answers that his accuser lies, the judge then ordains the duel. Is not this the modern point of honour, by which to be given the lie is an insult which can only be wiped out by blood?

From Germany the trial by judicial combat rapidly spread to every country of Europe. In France it was first confined to criminal causes, but this restriction was removed by Louis IX., who made it legal in civil matters as well, with the one proviso that in cases of debt the amount must exceed twelve deniers. By Philippe le Bel it was again confined in civil cases to questions of disputed inheritance, and forbidden altogether during the war between England and France. In 1385 a duel was fought, the result of which was so preposterous that even the most superstitious began to lose faith in the efficacy of such a judgment of God. A certain Jacques Legris was accused by the wife of Jean Carrouge of having introduced himself by night in the guise of her husband, and thus abused her. A duel was ordained by the Parliament, which was fought in the presence of Charles VI. Legris was defeated and hanged on the spot. Not long after a criminal arrested for some other offence confessed himself to be the author of the outrage. No institution could long survive so open a confutation. Henceforward the duel in France ceases to be an appeal to Heaven, and becomes merely a satisfaction of wounded honour. The last instance of a duel authorized by the magistrates, and conducted according to the forms of law, was the famous one between François de Vivonne de la Châtaignerie and Guy Chabot de Jarnac. The duel was fought on the 10th of July 1547 in the court-yard of the château of St Germain-en-Laye, in the presence of the king and a large assembly of courtiers. It was memorable in two ways. It enriched the French language with a new phrase; a sly and unforeseen blow, such as that by which De Jarnac worsted La Châtaignerie has since been called a *coup de Jarnac*. And Henry, grieved at the death of his favourite, swore a solemn oath that he would never again permit a duel to be fought. This led to the first of the many royal edicts against duelling.

In England, it is now generally agreed that the wager of battle did not exist before the time of the Norman Conquest. Some previous examples have been adduced, but

on examination they will be seen to belong rather to the class of single combats between the champions of two opposing armies. One such instance is worth quoting as a curious illustration of the superstition of the time. It occurs in a rare tract printed in London, 1610, *The Dudlo, or Single Combat*. "Danish irruptions and the bad aspects of Mars having drenched the common mother earth with her sounes' blood streames, under the reigne of Edmund, a Saxon monarch, misso in compendium (so worthy Camden expresseth it) bello utriusque gentis fata Edmundo Anglorum et Canuto Danorum regibus commissa fuerunt, qui singulari certamine de summa imperij in hac insula (that is, the Eight in Glostershire) depugnarunt." By the laws of William the Conqueror the trial by battle was only compulsory when the opposite parties were both Normans, in other cases it was optional. As the two nations were gradually merged into one, this form of trial spread, and until the reign of Henry II. it was the only mode for determining a suit for the recovery of land. The method of procedure is admirably described by Shakespeare in the opening scene in *Richard II*, where Henry of Bolingbroke, duke of Hereford, challenges Thomas duke of Norfolk, and in the mock-heroic battle between Horner the Armourer and his man Peter in *Henry VI.*, and by Sir W. Scott in the *Fair Maid of Perth*, where Henry Gow appears before the king as the champion of Magdalen Proudfoot. The judicial duel never took root in England as it did in France. In civil suits it was superseded by the grand assize of Henry II., and in cases of felony by indictment at the prosecution of the Crown. One of the latest instances occurred in the reign of Elizabeth, 1571, when the lists were actually prepared and the justices of the common pleas appeared at Tothill Fields as umpires of the combat. Fortunately the petitioner failed to put in an appearance, and was consequently nonsuited (See Spelman, *Glossary*, s.v. "Campus"). As late as 1817 Lord Ellenborough, in the case of Thornton v. Ashford, pronounced that "the general law of the land is that there shall be a trial by battle in cases of appeal unless the party brings himself within some of the exceptions." Thornton was accused of murdering Mary Ashford, and claimed his right to challenge the appellant, the brother of the murdered girl, to wager of battle. His suit was allowed, and, the challenge being refused, the accused escaped. Next year the law was abolished (59 Geo. III., c. 46).

In sketching the history of the judicial combat we have traced the parentage of the modern duel. Strip the former of its legality, and divest it of its religious sanction, and the latter remains. We are justified, then, in dating the commencement of duelling from the abolition of the wager of battle. To pursue its history we must return to France, the country where it first arose, and the soil on which it has most flourished. The causes which made it indigenous to France are sufficiently explained by the condition of society and the national character. As Buckle has pointed out, duelling is a special development of chivalry, and chivalry is one of the phases of the protective spirit which was predominant in France up to the time of the Revolution. Add to this the keen sense of personal honour, the susceptibility, and the pugnacity which distinguish the French race. Montaigne, when touching on this subject in his essays, says, "Put three Frenchmen together on the plains of Libya, and they will not be a month in company without scratching one another's eyes out." The third chapter of d'Audiguiers *Ancien usage des duels* is headed, "Pourquoi les seuls Français se battent en duel." English literature abounds with allusions to this characteristic of the French nation. Lord Herbert of Cherbury, who was ambassador at the court of Louis XIII., says, "There is scarce a Frenchman worth looking on who has not killed

his man in a duel." Ben Jonson, in his *Magnetic Lady*, makes Compass, the scholar and soldier, thus describe France, "that garden of humanity":—

There every gentleman professing arms
Thanks he is bound in honour to embrace
The bearing of a challenge for another,
Without or que'stioning the cause or asking
Least colour of a reason.

Duels were not common before the 16th century. Hallam attributes their prevalence to the barbarous custom of wearing swords as a part of domestic dress, a fashion which was not introduced till the later part of the 15th century. In 1560 the states-general at Orleans supplicated Charles IX. to put a stop to duelling. Hence the famous ordinance of 1566, drawn up by the Chancellor de l'Hôpital, which served as the basis of the successive ordinances of the following kings. Under the frivolous and sanguinary reign of Henry III., "who was as eager for excitement as a woman," the rage for duels spread till it became almost an epidemic. In 1602 the combined remonstrances of the church and the magistrates extorted from the king an edict condemning to death whoever should give or accept a challenge or act as second. But public opinion was revolted by such rigour, and the statute remained a dead letter. A duel forms a fit conclusion to the reign. A hair-brained youth named L'Isle Marivaux swore that he would not survive his beloved king, and threw his cartel into the air. It was at once picked up, and Marivaux soon obtained the death he had courted. Henry IV. began his reign by an edict against duels, but he was known in private to favour them; and, when De Crequi asked leave to fight Don Philip of Savoy, he is reported to have said, "Go, and if I were not a king I would be your second." Fontenay-Mareuil says, in his *Mémoires*, that in the eight years between 1601 and 1609, 2000 men of noble birth fell in duels. In 1609 a more effective measure was taken at the instance of Sally by the establishment of a court of honour. The edict decrees that all aggrieved persons shall address themselves to the king, either directly or through the medium of the constables, marshals, &c.; that the king shall decide, whether, if an accommodation could not be effected, permission to fight should be given; that the aggressor, if pronounced in the wrong, shall in any case be suspended from any public office or employment, and be mulcted of one-third of his revenue till he has satisfied the aggrieved party, that any one giving or receiving a challenge shall forfeit all right of reparation and all his offices; that any one who kills his adversary in an unauthorized duel shall suffer death without burial, and his children shall be reduced to villanage; that seconds, if they take part in a duel, shall suffer death, if not, shall be degraded from the profession of arms. This edict has been pronounced by Henri Martin "the wisest decree of the ancient monarchy on a matter which involves so many delicate and profound questions of morals, politics, and religion touching civil rights" (*Histoire de France*, x. 466).

In the succeeding reign the mania for duels revived. De Houssaye tells us that in Paris when friends met the first question was, "Who fought yesterday? who is to fight to-day?" They fought by night and day, by moonlight and by torch-light, in the public streets and squares. A hasty word, a misconceived gesture, a question about the colour of a riband or an embroidered letter, such were the commonest pretexts for a duel. The slighter and more frivolous the dispute, the less were they inclined to submit them to the king for adjudication. Often, like gladiators or prize-fighters, they fought for the pure love of fighting. A misunderstanding is cleared up on the ground. "N'importe," cry the principals, "puisque nous sommes ici, battons-nous." Seconds, as Montaigne tells us, are no

longer witnesses, but must take part themselves unless they would be thought wanting in affection or courage; and he goes on to complain that men are no longer contented with a single second, "c'était anciennement des duels, ce sont à cette heure recontres et batailles." There is no more striking instance of Richelieu's firmness and power as a statesman than his conduct in the matter of duelling. In his *Testament Politique* he has assigned his reasons for disapproving it as a statesman and ecclesiastic. But this disapproval was turned to active detestation by a private cause. His elder brother, the head of the house, had fallen in a duel stabbed to the heart by an enemy of the cardinal. Already four edicts had been published under Louis XIII. with little or no effect, when in 1626 there was published a new edict condemning to death any one who had killed his adversary in a duel, or had been found guilty of sending a challenge a second time. Banishment and partial confiscation of goods were awarded for lesser offences. But this edict differed from preceding ones not so much in its severity as in the fact that it was the first which was actually enforced. The cardinal began by imposing the penalties of banishment and fines, but, these proving ineffectual to stay the evil, he determined to make a terrible example. To quote his own words to the king, "Il s'agit de couper la gorge aux duels ou aux édits de votre Majesté." The count de Boutteville, a renommeist who had already been engaged in twenty-one affairs of honour, determined out of pure bravado to fight a twenty-second time. The duel took place at mid-day on the Place Royal. De Boutteville was arrested with his second, the count de Chapelles; they were tried by Parliament, condemned, and, in spite of all the influence of the powerful house of Montmorenci, of which De Boutteville was a branch, they were both beheaded at Grève, June 21, 1627. For a short time the ardour of duellists was cooled. But the lesson soon lost its effect. Only five years later we read in the *Mercur de France* that two gentlemen who had killed one another in a duel were, by the cardinal's orders, hanged on a gallows, stripped, and with their heads downwards, in the sight of all the people. This was a move in the right direction, since, for fashionable vices, ridicule and ignominy is a more drastic remedy than death. It was on this principle that Caraccioli, prince of Melfi, when viceroi of Piedmont, finding that his officers were being decimated by duelling, proclaimed that all duels should be fought on the parapet of the Ponte Vecchio, and if one of the combatants chanced to fall into the river he should on no account be pulled out.

Under the long reign of Louis XIV. many celebrated duels took place, of which the most remarkable were that between the duke of Guise and Count Coligny, the last fought on the Place Royal, and that between the dukes of Beaufort and Nemours, each attended by four friends. Of the ten combatants, Nemours and two others were killed on the spot, and none escaped without some wound. No less than eleven edicts against duelling were issued under le Grand Monarque. That of 1643 established a supreme court of honour composed of the marshals of France; but the most famous was that of 1679, which confirmed the enactments of his predecessors, Henry IV. and Louis XII. At the same time a solemn agreement was entered into by the principal nobility that they would never engage in a duel on any pretence whatever. A medal was struck to commemorate the occasion, and the firmness of the king, in refusing pardon to all offenders, contributed more to restrain this scourge of society than all the efforts of his predecessors.

The subsequent history of duelling in France may be more shortly treated. The two great Frenchmen whose writings preluded the French Revolution both set their faces against it. Voltaire had indeed, as a young man, in

obedience to the dictates of society, once sought satisfaction from a nobleman for a brutal insult, and had reflected on his temerity in the solitude of the Bastille.¹ Henceforward he inveighed against the practice, not only for its absurdity, but also for its aristocratic exclusiveness. Rousseau had said of duelling, "It is not an institution of honour, but a horrible and barbarous custom, which a courageous man despises and a good man abhors." Then came the Revolution, which levelled at a blow the huge structure of feudalism, and with it the duel, its instrument and apauage. *Pauci tamen subcrunt prisca vestigia fraudis.* With each reaction against the revolutionary spirit and return to feudal ideas the duel reappears. Under the Directory it again became fashionable among the upper classes. Napoleon was a sworn foe to it. "Bon duelliste mauvais soldat" is one of his best known sayings; and, when the king of Sweden sent him a challenge, he replied that he would order a fencing-master to attend him as plenipotentiary. After the battle of Waterloo duels such as Lever loves to depict were frequent between disbanded French officers and those of the allies in occupation. The restoration of the Bourbons brought with it a fresh crop of duels. Since then they have been chiefly confined to military circles, and a small section of Parisian journalists. Yet a list of duels fought within the last fifty years in France would occupy no inconsiderable space, and would include some of the most famous names in literature and politics, Emile de Girardin, Armand Carrel, Lamartine, Alexandre Dumas, Ledru Rollin, Edmond About, Sainte-Beuve, and M. Thiers. Even at the present hour men like Paul de Cassagnac exercise a sinister power, and an editor of the *Pays* must be an adept with swords and pistols no less than a skilled writer.

As a complete history of duelling would far exceed the limits of this article, we have preferred to trace in some detail its rise and fall in the country where it has most prevailed. We are thus compelled to pass by other nations, and conclude with a brief epitome of its annals at home. Duelling did not begin in England till some hundred years after it had arisen in France. There is no instance of a private duel fought in this country before the 16th century, and they are rare before the reign of James I. A very fair notion of the comparative popularity of duelling, and of the feeling with which it was regarded at various periods, might be gathered by examining the part it plays in the novels and lighter literature of the times. The earliest duels we remember in fiction are that in the *Monastery* between Sir Piercie Shafton and Halbert Glendinning, and that in *Kenilworth* between Tressilian and Varney. (That in *Anne of Geierstein* either is an anachronism or must reckon as a wager by battle.) Under James I. we have the encounter between Nigel and Lord Dalgarno. The greater evil of war, as we observed in French history, expels the lesser, and the literature of the Commonwealth is in this respect a blank. With the Restoration there came a reaction against Puritan morality, and a return to the gallantry and loose manners of French society, which is best represented by the theatre of the day. The drama of

¹ Voltaire met the Chevalier Rohan-Chabot at the house of the Marquis of Sully. The Chevalier, offended by Voltaire's free speech, insolently asked the Marquis, "Who is that young man?" "One," replied Voltaire, "who, if he does not parade a great name, honours that he bears." The Chevalier said nothing at the time, but, seizing his opportunity, inveigled Voltaire into his coach, and had him beaten by six of his footmen. Voltaire set to work to learn fencing, and then sought the Chevalier in the theatre, and publicly challenged him. A *bon-mot* at the Chevalier's expense was the only satisfaction that the philosopher could obtain. "Monsieur, si quelque affaire d'intérêt ne vous a point fait oublier l'outrage dont j'ai à me plaindre, j'espère que vous m'en rendrez raison." The Chevalier was said to employ his capital in petty usury.

the Restoration abounds in duels. Passing on to the reign of Queen Anne, we find the subject frequently discussed in the *Tatler* and the *Spectator*, and Addison points in his happiest way the moral to a contemporary duel between Mr Thornhill and Sir Cholmeley Dering. "I come not," says Spinomont to King Pharamond, "I come not to implore your pardon, I come to relate my sorrow, a sorrow too great for human life to support. Know that this morning I have killed in a duel the man whom of all men living I love best." No reader of *Esmond* can forget Thackeray's description of the doubly fatal duel between the duke of Hamilton and Lord Mohun, which is historical, or the no less life-like though fictitious duel between Lord Mohun and Lord Castlewood. Throughout the reigns of the Georges they are frequent. Richardson expresses his opinion on the subject in six voluminous letters to the *Literary Repository*. Sheridan, like Farquhar in a previous generation, not only dramatized a duel, but fought two himself. Byron thus commemorates the bloodless duel between Tom Moore and Lord Jeffrey—

Can none remember that eventful day,
That ever glorious almost fatal fray,
When Little's leadless pistols met the eye,
And Bow Street myrmidons stood laughing by!

As we approach our own times they become rarer in fiction. Thackeray, indeed, who represents an older generation, and the worse side of aristocratic society, abounds in duels. His royal highness the late lamented commander-in-chief had the greatest respect for Major Macmurdo, as a man who had conducted scores of affairs for his acquaintance with the greatest prudence and skill; and Rawdon Crawley's duelling pistols, "the same which I shot Captain Marker," have become a household word. Dickens, on the other hand, who depicts contemporary English life, and mostly in the middle classes, in all his numerous works has only three, and George Eliot never once refers to a duel. Tennyson, using a poet's privilege, has laid the scene of a duel in the year of the Crimean war, but he echoes the spirit of the times when he stigmatizes "the Christless code that must have life for a blow."

To pass from fiction to fact, a list of the celebrated public men who in the last century have fought duels will suffice to shew the magnitude of the evil.—Fox, Pitt, William Pulteney and Lord Hervey, Canning and Lord Castlereagh, the duke of York, the duke of Richmond, Wilkes, Sir Francis Burdett, Grattan, Daniel O'Connell. For particulars we must refer the reader to the respective names.

The year 1808 is memorable in the annals of duelling in England. Major Campbell was sentenced to death and executed for killing Captain Boyd in a duel. In this case it is true that there was a suspicion of foul play; but in the case of Lieutenant Blundell, who was killed in a duel in 1813, though all had been conducted with perfect fairness, the surviving principal and the seconds were all convicted of murder and sentenced to death, and, although the royal pardon was obtained, they were all cashiered. The next important date is the year 1843, when public attention was painfully called to the subject by a duel in which Colonel Fawcett was shot by his brother-in-law Lieutenant Monro. The survivor, whose career was thereby blasted, had, it was well known, gone out most reluctantly, in obedience to the then prevailing military code. A full account of the steps taken by the late Prince Consort, and of the correspondence which passed between him and the duke of Wellington, will be found in the *Life of the Prince* by Theodore Martin. The duke, unfortunately, was not an unprejudiced counsellor. Not only had he been out himself, but, in writing to Lord Londonderry on the occasion of the duel between the marquis and Ensign Battier in 1824,

he had gone so far as to state that he considered the probability of the Hussars having to fight a duel or two a matter of no consequence. But though the proposal of the prince to establish courts of honour met with no favour, yet it led to an important amendment of the articles of war (April 1844). The 98th of the articles now in force ordains that "every person who shall fight or promote a duel, or take any steps thereto, or who shall not do his best to prevent a duel, shall, if an officer, be cashiered or suffer such other penalty as a general court-martial may award." By the same articles, to accept or to receive apologies for wrong or insult given or received is declared suitable to the character of honourable men. The effect has been that duels, which had already been banished from civil society, have been no less discredited in the English army. In the German army, on the contrary, the institution survives in full force, and is recognized by law. A full account of the courts of honour to regulate disputes and duels among German officers will be found in *The Armed Strength of the German Empire*.

Any formal discussion of the morality of duelling is, in England at least, happily superfluous. No fashionable vice has been so unanimously condemned both by moralists and divines, and in tracing its history we are reminded of the words of Tacitus, "in civitate nostra et vetabitur semper et retinebitur." Some, however, of the problems moral and social which it suggests may be shortly noticed. That duelling flourished so long in England the law is perhaps as much to blame as society. It was doubtless from the fact that duels were at first a form of legal procedure that English law has refused to take cognizance of private duels. A duel in the eye of the law differs nothing from an ordinary murder. Our greatest legal authorities, from the time of Elizabeth downwards, such as Coke, Bacon, and Hale, have all distinctly affirmed this interpretation of the law. But here as elsewhere the severity of the penalty defeated its own object. The public conscience revolted against a Draconian code which made no distinction between wilful murder and a deadly combat, wherein each party consented to his own death or submitted to the risk of it. No jury could be found to convict when conviction involved in the same penalty a Fox or a Pitt and a Turpin or a Brownrigg. Such, however, was the conservatism of English publicists that Bentham was the first to point out clearly this defect of the law, and propose a remedy. In his *Introduction to the Principles of Morals and Legislation*, published in 1789, Bentham discusses the subject with his usual boldness and logical precision. In his exposition of the absurdity of duelling considered as a branch of penal justice, and its inefficiency as a punishment, he only restates in a clearer form the arguments of Paley. So far there is nothing novel in his treatment of the subject. But he soon parts company with the Christian moralist and proceeds to show that duelling does, however rudely and imperfectly, correct and repress a real social evil. "It entirely effaces a blot which an insult imprints upon the honour. Vulgar moralists, by condemning public opinion upon this point, only confirm the fact." He then points out the true remedy for the evil. It is to extend the same legal protection to offences against honour as to offences against the person. The legal satisfactions which he suggests are some of them extremely grotesque. Thus for an insult to a woman, the man is to be dressed in a woman's clothes, and the retort to be inflicted by the hand of a woman. But the principle indicated is a sound one, that in offences against honour the punishment must be analogous to the injury. Doubtless, if Bentham were now alive, he would allow that the necessity for such a scheme of legislation had in a great measure passed away. That duels have since become extinct is no doubt principally owing to social changes, but it may

be in part ascribed to improvements in legal remedies in the sense which Bentham indicated. A notable instance is Lord Campbell's Act of 1843, by which, in the case of a newspaper libel, a public apology coupled with a pecuniary payment is allowed to bar a plea. In the Indian Code there are special enactments concerning duelling, which is punishable not as murder but as homicide.

Suggestions have from time to time been made for the establishment of courts of honour, but the need of such tribunals is doubtful, while the objections to them are obvious. The present tendency of political philosophy is to contract rather than extend the province of law, and any interference with social life is justly resented. Real offences against reputation are sufficiently punished, and the rule of the lawyers, that mere scurrility or opprobrious words, which neither of themselves import nor are attended with any hurtful effects, are not punishable, seems on the whole a wise one. What in a higher rank is looked upon as a gross insult may in a lower rank be regarded as a mere pleasantry or a harmless joke. Among the lower orders offences against honour can hardly be said to exist; the learned professions have each its own tribunal to which its members are amenable; and the highest ranks of society, however imperfect their standard of morality may be, are perfectly competent to enforce that standard by means of social penalties without resorting either to trial by law or trial by battle.

(F. S.)

DUFOUR, WILHELM HEINRICH (1787–1875), a Swiss general, director of the topographical survey of Switzerland, was born at Constance, of Genevese parents temporarily in exile, on the 15th September 1787. During his early studies at Geneva he showed no special capacity, and he took a low place in the entrance examination to the École Polytechnique at Paris, to which he went in 1807. By two years' close study he so greatly improved his position that he was ranked among the first in the exit examination. Immediately on leaving the school he received a commission in the engineers, and was sent to serve in Corfu, which was blockaded by the English. During the Hundred Days he attained the rank of captain, and was employed in raising fortifications at Grenoble for its defence against the Austrians. After the peace that followed Waterloo he retired from the French army on half-pay, and resumed his status as a Swiss citizen. Refusing the offer of a command at Briançon on condition that he would again adopt the French nationality, he devoted himself to the military service of his native land. From 1819 to 1830 he was chief instructor in the military school of Thonon, which had been founded mainly through his instrumentality. Among other distinguished foreign pupils he had the honour of instructing Prince Louis Napoleon, afterwards emperor of the French. In 1827 he was raised to the rank of colonel, and commanded the Federal army in a series of field manœuvres. In 1831 he became chief of the staff, and soon afterwards he was appointed quartermaster-general. The most important work of his life was commenced in 1833, when the Diet commissioned him to superintend the execution of a trigonometrical survey of

Switzerland. He had already proved his fitness for the task by making a cadastral survey of the canton of Geneva, and publishing a map of the canton in four sheets on the scale of $\frac{1}{25000}$. The larger work occupied thirty-two years, and was accomplished with complete success. The map in 25 sheets on the scale of $\frac{1}{100000}$ was published at intervals between 1842 and 1865, and is an admirable specimen of cartography. In recognition of the ability with which Dufour had carried out his task, the Federal Council in 1868 ordered the highest peak of Monte Rosa to be named Dufour Spitze. In 1847 Dufour received the command of the Federal Army, which was employed in reducing the revolted Catholic cantons to submission. The quickness and thoroughness with which he performed the painful task, and the wise moderation with which he treated his vanquished fellow-countrymen, were acknowledged by a gift of 60,000 francs from the Diet and various honours from different cities and cantons of the confederation. In politics he belonged to the moderate conservative party, and he consequently lost a good deal of his popularity in 1848. In 1864 he presided over the International Conference which framed the so-called Geneva Convention as to the treatment of the wounded in time of war, &c. He died on the 14th July 1875. Dufour was the author of a *Mémoire sur l'artillerie des anciens et sur celle du moyen-âge* (1840), *De la fortification permanente* (1850), *Manuel de tactique pour les officiers de toutes armes* (1842), and various other works in military science.

DUFRENOY, PIERRE ARMAND, geologist and mineralogist, was born at Sevrin, in the department of Seine-et-Oise, in France, in 1792, and died March 20, 1857. After leaving the Imperial Lyceum in 1811, he studied till 1813 at the Polytechnic School, and then, at the age of twenty-one, entered the corps des mines. In conjunction with M. Élie de Beaumont he in 1841 published a great geological map of France, the result of investigations carried on during thirteen years (1823–1836). Five years (1836–41) were spent in writing the text to accompany the map. The two authors had already together published *Voyage géologique en Angleterre* (1827, 2d ed. 1837–39), *Mémoires pour servir à une description géologique de la France* (1830–38), and a *Mémoire* on Cantal and Mont-Dore (1833). Other literary productions of Dufrenoy are an account of the iron-mines of the eastern Pyrenees (1834), a treatise on mineralogy (1844, 2d ed. 1856–60), and numerous papers contributed to the *Annales des Mines* and other scientific publications, one of the most interesting of which is entitled *Des terrains volcaniques des environs de Naples*. Dufrenoy was a member of the Academy of Sciences, a commander of the Legion of Honour, an inspector-general of mines, and professor of geology at *L'École des Ponts et Chaussées*, and of mineralogy at the Imperial School of Mines, of which latter institution he was the director.

DUFRESNY, CHARLES RIVIÈRE (1648–1728), a French dramatist, better remembered by the comedy of his own life than by any of the numerous plays which he contributed to the Théâtre Italien and the Théâtre Français. The fact that his grandfather was an illegitimate son of Henry IV. procured him the liberal patronage of Louis XIV., who not only gave him the post of *1^{er} de la chambre*, but affixed his name now to one lucrative privilege and now to another. The protégé, however, appeared as eager to squander as the king was to bestow; and the pathetic confession of exhausted generosity—"I cannot enrich Dufresny"—was probably taken by the careless spendthrift as a signal compliment; though to one of his friends who consoled him with the remark that poverty is no sin, he replied, "*It is true*." On Louis's death he was almost as necessitous as if Louis had never lived; but he obtained 200,000 francs from the duke of Orleans in answer to an ingenious request

that his highness for his own glory would leave Dufresny in his excessive indigence as a sole example of the condition of the whole kingdom before the golden days of his regency. As if to furnish a piquant commentary on the proverb that poverty makes us acquainted with strange bed-fellows, he married his washerwoman in discharge of her bill—a whimsicality which supplied Lo Sago with an episode in the *Diable Boiteux*, and was made the subject of a comedy by J. M. Deschamps—*Charles Rivière Dufresny, ou le mariage impromptu*. Clever, versatile, and superficial, he obtained in his own day a considerable reputation not only as an author and a wit, but also as a landscape gardener and architectural designer: to his great patron he furnished plans for the park at Versailles, and was appointed in return overseer of the royal grounds. He died at Paris in 1728 in a house—*la maison de Plin*—which he had built with the regent's bounty. His plays, destitute for the most part of all higher qualities, but abounding in sprightly wit and pithy sayings, are no longer acted; though a few of the many in the six volumes of his *Théâtre* (Paris, 1731) are still read. *L'esprit de contradiction* (first acted in 1700), *Le double veuvage* (1702), *La coquette du village*, and *Le mariage fait et rompu* are reprinted in the second volume of Diderot's *Chefs-d'œuvre des auteurs comiques*; and his contributions to the *Théâtre Italien*, produced in collaboration with Regnard or Biancamano, may be found in Gherardi's collection. A volume of *Poésies diverses*, two volumes of *Nouvelles historiques*, Leyde, 1692, and *Les amusements sérieux et comiques d'un Suédois*, 1807, a work to which Montesquieu was indebted for the idea of his *Lettres Persanes*, complete the list of Dufresny's writings. Two volumes of *Œuvres Choies* were edited by Auger in 1801.

DUGDALE, SIR WILLIAM (1605–1686), an eminent English antiquary, the only son of John Dugdale, who belonged to an old Lancashire family, but had sold his property in that county and bought the estate of Shustoke, near Coleshull, in Warwickshire, was born on the 12th September 1605. He received the early part of his education from Thomas Sibley, a curate near Shustoke, and attended from his tenth to his fifteenth year the Free School at Coventry, whence returning to his father, he read with him for some time law and history. In compliance with his father's wish, who was old and infirm, and desired to see him married before he died, he was married at the early age of seventeen to the daughter of a gentleman in the county of Stafford. He lived in his wife's father's house until the death of his own father in 1624, and soon thereafter went to reside at Fillongley, near Shustoke, an estate formerly purchased for him by his father. In 1625 he purchased the manor of Blyth, in the parish of Shustoke, and, preferring it as a place of residence, removed thither in 1626. His inclination to the study of antiquities manifested itself at an early age, and received its first encouragement from Samuel Roper, a barrister of Lincoln's Inn. After his settlement at Blyth Hall he made the acquaintance of some gentlemen interested in antiquities, who enabled him to obtain a sight of the old "deeds and evidences" of the county families of Warwickshire, and "divers antient writings of consequence," with the view of his writing a history of that county. In 1635 he accompanied Sir Simon Archer to London, and was by him introduced to Sir Henry Spelman, which led to his acquaintance with Thomas, earl of Arundell, then earl marshal of England, by whom he was, in 1638, created a pursuivant of arms extraordinary by the name of Blanche Lyon, and in 1639 rouge-croix pursuivant in ordinary. About this time he agreed to write his work on *Monastery Foundations*, and, having a lodging in the Herald's Office, he now spent much of his time in London in order to augment his collections out of the records of the Tower and other places in the city. In

1641 Sir Christopher Hatton, a member of the House of Commons, dreading the near approach of the revolutionary storm which soon thereafter broke over England, and the ruin that might then ensue, got him to make exact drafts of all the monuments in Westminster Abbey and the principal churches in England, including Peterborough, Ely, Norwich, Lincoln, Newark, Beverley, Southwell, Kingston-upon-Hull, York, Selby, Chester, Lichfield, Tamworth, and Warwick. He received and obeyed, in June 1642, the summons of Charles I. to attend him at York, whither, on the outbreak of the revolution, the king had betaken himself for the sake of greater security. Learning the spread of the revolution in Warwickshire, Charles deputed him to summon to surrender the castle of Banbury, in Oxford, and the castle of Warwick, which were being rapidly filled with ammunition and rebels. Banbury obeyed, but Warwick, being better prepared, contemned the summons and its inmates were proclaimed traitors. He also summoned the city of Coventry; and, accompanying Sir Richard Willys as guide, he was present at the battle of Cudworth Field, the result of which he communicated to the king. He remained at Oxford with the king till the surrender of the garrison in 1646, and witnessed the battle of Edgehill, of the field of which he made afterwards an exact survey, noting how the armies were drawn up, and where and in what direction the various movements took place, and marking the graves of the slain. In November 1642 he was admitted M.A. of the university, and in 1644 the king created him Chester-Herald. While at Oxford he made a journey to Worcester, where—with the purpose of increasing his collections for his history of Warwickshire—he perused the registers of the bishop and of the dean and chapter; and during his Oxford leisure he applied himself also to the search for antiquities in the libraries and in the private houses. When Oxford surrendered he continued his antiquarian researches in London along with Richard Dodsworth for their joint work on the monasteries, which was published successively in single volumes in 1655, 1664, and 1673. At the Restoration he obtained the office of Norroy king-at-arms, and in 1677 was created garter principal king-at-arms, and was knighted. He died at Blyth Hall, 10th February 1686.

Besides the works on Warwickshire, published in 1656, and *Monasticon Anglicanum*, republished in 6 vols in 1817–30, and again in 8 volumes in 1846, Sir William Dugdale is the author of *History of St Paul's Cathedral* (1658), the *Baronage of England* (3 vols. 1675–6), and other works of less importance. His life, written by himself up to 1673, with his diary and correspondence, and an index to his manuscript collections, was edited by William Hamper, and published in 1827.

DUGONG (*Halicore*), a genus of herbivorous Cetacea, forming, along with the Sea-Cows (*Manatus*), and the now extinct *Rhytina*, the sub-order Sirenia. In this genus the head is small, and is abruptly truncated in front, the snout being remarkably obtuse and furnished with bristles. The intermaxillary bones are enormously developed, and from these proceed two large incisive teeth or tusks, which are well developed in the male, but which in the female are arrested in their growth, and remain concealed beneath the surface. There are never more than five molar teeth on each side of either jaw, or twenty in all, and these are flat on the grinding surface. The flippers are unprovided with nails, and the tail is broad, and differs from that of the manatee in being crescent-shaped instead of rounded. The bones are very hard and firm, and take a polish equal to that of ivory. The dugongs frequent the shallow waters of the tropical seas, extending from the east coast of Africa north of the mouth of the Zambesi river, along the shores of the Indian, Malayan, and Australian seas, where they may be seen basking on the surface of the water, or browsing on submarine pastures of *Algae* and *Fuci*, for which the

thick obtuse lips and truncated snout preeminently fit them. They are gregarious, feeding in large numbers in localities where they are not often disturbed. The female produces a single young one at a birth, and is remarkable for the great affection it shows for its offspring, so that when the young dugong is caught there is no difficulty in capturing the mother with it. There are two species—the Indian Dugong (*Halicore indicus*) and the Australian Dugong (*Halicore australis*). The former is very abundant along the shores of the Indian Ocean, and is captured in large numbers by the Malaysians, who esteem its flesh as a great delicacy; while the lean portions, especially of young specimens, are regarded by Europeans even as excellent eating. It is generally taken by spearing, the main object of the hunter being to raise the tail out of the water, when the animal becomes perfectly powerless. It seldom attains a length of more than 8 or 10 feet. The Australian Dugong is a larger species, attaining sometimes a length of 15 feet. It occurs along the Australian coast from Moreton Bay to Cape York, and is highly valued by the natives, who hunt for it with spears, and gorge themselves with its flesh, when they are fortunate enough to secure a carcass. In recent years the oil obtained from the blubber of this species has been largely used in Australia as a substitute for cod-liver oil. It does not contain iodine, but is said to possess all the therapeutic qualities of cod-liver oil without its nauseous taste. A full grown dugong yields from 10 to 12 gallons of oil, and this, according to Bennet, "forms in cold weather a thick mass, and requires to be melted before a fire previously to being used." According to the same authority, the flesh of the Australian dugong is easy of digestion, the muscular fibre when fresh resembling beef, and when salted having the flavour of excellent bacon. In the earliest Australian dugong fishery, natives were employed to harpoon these cetaceans; they soon, however, became too wary to allow themselves to be approached near enough for this purpose, and the harpoon was abandoned for the net. The latter is spread at night, and in its meshes dugongs are caught in considerable numbers. The skin is nearly half an inch thick, and can be made into gelatine or glue.

DUGUAY-TROUEN, RENÉ (1673–1736), a famous French admiral, was the son of a sea captain, and was born at St Malo on the 10th June 1673. He was originally intended for the church, and studied with that view at Rennes and Caen; but on the breaking out of the war with England and Holland in 1689 he obtained leave to enter the marine. Accordingly he embarked in the capacity of a volunteer on board a small vessel of 18 guns, equipped by his family, and during the first three months his courage was tried by a violent tempest, an imminent shipwreck, the boarding of an English ship, and the threatened destruction of his own vessel by fire. The following year, as a volunteer in a vessel of 28 guns, he carried off the honours in a bloody combat with an English fleet of five merchant vessels. The courage he then showed was so remarkable that in 1691, at the age of eighteen, he obtained the command of a frigate of 14 guns, when, having been thrown by a tempest on the coast of Ireland, he burned two English ships in the river Limerick. In 1694 his vessel of 40 guns was captured by the English, and, being taken prisoner, he was confined in the castle of Plymouth, where, however, he made love to the daughter of the jailer, and by her aid managed to escape. He then obtained command of a vessel of 48 guns, and made a capture of English vessels on the Irish coast. In 1696 he made a brilliant capture of Dutch vessels, and the king hearing an account of the affair raised him in 1697 to the rank of captain of a frigate. In 1704–5 he desolated the coasts of England. In 1706 he was raised to the rank of captain of a vessel of

the line. In 1707 he was made chevalier of the order of St Louis, and captured the greater part of an English convoy of troops and munitions bound for Portugal. His most glorious action was the capture in 1711 of Rio Janeiro, on which he imposed a heavy contribution. In 1715 he was made chief of a squadron, and in 1728 commander of the order of St Louis and lieutenant-general. In 1731 he commanded a squadron for the protection of French commerce in the Levant. He died 27th September 1736.

DU GUESCLIN, BERTRAND (c. 1314–1380), constable of France, the most famous French warrior of his age, was born of an ancient but undistinguished family, at the castle of La Motte-Broon, near Rennes, about 1314. The date is doubtful, the authorities varying between 1311 and 1324. The name is spelt in various ways in contemporary records, e.g., Claquin, Klesquin, Guesquin, Glayaquin, &c. The familiar form is found on his monument at St Denis, and in some legal documents of the time. In his boyhood Bertrand was a dull learner, spending his time in open air sports and exercises, and could never read or write. He was remarkable for ugliness, and was an object of aversion to his parents. He first made himself a name as a soldier at the tournament held at Rennes in 1338 to celebrate the marriage of Charles of Blois with Jeanne de Penthièvre, at which he unseated the most famous competitors. But this playing at fighting was not enough for his ambition, and in the war which followed between Charles of Blois and John de Montfort, for the possession of the duchy of Brittany, he served his apprenticeship as a soldier. As he was not a great baron with a body of vassals at his command, he put himself at the head of a band of adventurers, and fought on the side of Charles and of France. He distinguished himself by a brilliant action at the siege of Vannes in 1342; and after that he disappears from history for some years. In 1351, having shortly before been made a knight, he was sent into England with the lords of Brittany to treat for the ransom of Charles of Blois, who had been defeated and captured by the English in 1347. When Rennes was besieged by the duke of Lancaster, in 1356, Du Guesclin forced his way with a handful of men into the town, and successfully defended it till June 1357, when the siege was raised in pursuance of the truce of Bordeaux. For this service he was rewarded with the lordship of Roche d'Aïrien. At the expiration of the truce he distinguished himself by the defence of Dinan, and here he engaged in single combat with Sir Thomas Cantelmay. Shortly afterwards he married; and about the same time he passed into the service of France, and greatly distinguished himself at the siege of Melun (1359). In April 1364, in conjunction with Boucicaut, he recovered Mantua and Meulan from the king of Navarre, and in May he defeated the Navarrese under Captal de Buch at Cocherel, and took their leader prisoner. The king now erected him: marshal of Normandy and count of Longueville. At the battle of Auray, in September of the same year, Charles of Blois was defeated and killed, and Du Guesclin taken prisoner, by Sir John Chandos. The grand companies beginning, after the close of the war, to play the part of brigands in France, it was necessary to get rid of them. Du Guesclin was ransomed for 100,000 crowns, and was charged to lead them out of France. He went to them into Spain, visiting Avignon on the way, and returning from the Pope a large sum of money and his old captain. Du Guesclin now supported Henry of Trastamare against Peter the Cruel, set the former upon the throne of Castile (1366), and was made constable of Castile and count of Trastamare. In the following year he was once more captured by the Black Prince, ally of Peter the Cruel of Navarre, but was soon released for a heavy ransom. Once more he fought for Henry, reinstated him on the throne

(1369), and was created duke of Molinas. In May 1370, at the command of Charles V., who named him constable of France, he returned to France. War had just been declared against England, and Du Guesclin was called to take part in it. For nearly ten years he was engaged in fighting against the English in the south and the west of France, recovering from them the provinces of Poitou, Guienne, and Auvergne, and thus powerfully contributing to the establishment of a united France. In 1373, when the duke of Brittany sought English aid against a threatened invasion by Charles V., Du Guesclin was sent at the head of a powerful army to seize the duchy, which he did; and two years later he frustrated by a defensive policy the attempt of the duke with an English army to recover it. Finding in 1379 that the king entertained suspicions of his fidelity to him, he resolved to give up his constable's sword and retire to Spain. His resolution was at first proof against remonstrance; but ultimately he received back the sword, and continued in the service of France. In 1380 he was sent into Languedoc to suppress disturbances and brigandage, provoked by the harsh government of the duke of Anjou. His first act was to lay siege to the fortress of Châteauneuf Randon, held by the English, strongly garrisoned and well provisioned. A day was fixed conditionally for capitulation. Meanwhile the great warrior was smitten with a mortal illness, and died, July 13, 1380. The commander led out the garrison and deposited the keys of the castle on the coffin of the hero. Du Guesclin lost his first wife in 1371, and married a second in 1373, but he left no legitimate children. His remains were interred, by order of the king, in the church of St Denis.

Of the numerous recent biographies of Du Guesclin, the most recent is the learned work by D F Jamous (Charleston, 1863), which was translated into French by J. Baissac by order of Marshal Count Randon, minister of war, and published in 1866.

DUHALDE, JEAN BAPTISTE (1674–1743), geographical writer, was born at Paris, February 1, 1674. In 1708 he entered into the Society of Jesus, and some time afterwards he was appointed to succeed Father Legobien, who had been intrusted with the duty of collecting and arranging the letters which they received from their missionaries in different quarters of the globe. He was also for some time secretary to the famous Father Le Tellier, confessor to the king of France. He died August 18, 1743. Duhalde is represented as a man of mild and amiable character, and as remarkable alike for his unaffected piety and unwearied industry. He was the author of some Latin poems, which do not evince any superior degree of excellence. The productions for which he is principally distinguished are—(1) *Lettres Éduquées et Curieuses écrites des Missions Étrangères*, which he edited with great ability from the ninth to the twenty-sixth volume inclusive, and which have been translated into English and German; and (2) *Description géographique, historique, chronologique, politique, et physique de l'Empire de la Chine et de la Tartarie Chinoise*, Paris, 1735, in four volumes large folio, with figures and an atlas by D. Anville. This work, the first in which China is described with so much exactness and detail, is a beautiful specimen of French typography. An English translation by Brookes was published in 1736 in 4 vols.

DUHAMEL, JEAN BAPTISTE (1624–1706), a French astronomer and physician, was the son of an advocate, and was born at Vire, in Normandy, in 1624. He commenced his studies at Cien, and completed them at Paris. At the age of eighteen he wrote a treatise on the *Spherics* of Theodosius, and added to it a tract on trigonometry, designed as an introduction to astronomy. At the age of twenty-one he became curé of Neuilly-sur-Marne, but without neglecting the duties of his calling, he continued to cultivate the physical sciences with zeal. In 1656 he was

named alraoner of the king; in 1663 he obtained the dignity of chancellor of the church of Bayeux; and in 1666, when Louis XIV. established the Royal Academy of Sciences, he was appointed perpetual secretary. He was preparing a history of the Academy when he died, August 6, 1706. He published numerous works on philosophy, divinity, and physical science.

DUHAMEL DU MONCEAU, HENRY LOUIS (1700–1782), a celebrated French botanist and agriculturist, was the son of Alexandre Duhamel, lord of Denainvilliers, and was born at Paris in 1700. He was placed at the Collège d'Harcourt, but made little progress in his studies, except that, notwithstanding the imperfect manner in which the natural sciences were there taught, he acquired such a taste for these branches of knowledge as led him to attend the lessons of Dufay and Bernard de Jussieu at the Jardin des Plantes. He now spent his time between the capital, where he pursued his botanical studies and held intercourse with scientists, and his estates at Gâtinais, where he employed his knowledge in arboricultural experiments. Having been requested by the Academy of Sciences to investigate the cause of the disease which was destroying the saffron plant in Gâtinais, he discovered that its destruction was owing to a parasitical fungus which attached itself to its roots. The work in which he demonstrated his discovery was judged worthy to appear in the transactions of the Academy, and gained him admission to that body in 1728. From then until his death he busied himself chiefly with making experiments in vegetable physiology, and recording and publishing his observations. Having learned from Sir Hans Sloane that madder possesses the property of giving colour to the bones, he fed animals successively on food mixed and unmixed with madder; and he found that their bones in general exhibited concentric strata of red and white, whilst the softer parts showed in the meantime signs of having been progressively extended. From a number of experiments he was led to believe himself able to explain the growth of bones, and to demonstrate a parallel between the manner of their growth and that of trees. Along with the celebrated naturalist Buffon, he made numerous experiments on the growth and strength of wood, one of the results of which was that he recommended the bark to be taken off the trees several years before they are cut down. He experimented also on the growth of the mistletoe, on layer planting, on smut in corn, and on the production of soda and potash by different vegetables. From the year 1740 he made meteorological observations, and kept records of the influence of the weather on agricultural production. Having been appointed inspector-general of marine, he applied his scientific acquirements to the improvement of nautical knowledge, subjecting everything to the test of facts and experiments. Duhamel's aim in his researches was rather to be useful than to gratify his own curiosity or to win fame. He made himself accessible to all who sought information from him, and his modesty was as great as his knowledge. He was scrupulous in the practice of his religious duties. He died August 13, 1782.

His works are generally of an elementary character, and from the minute details of their information are rather prolix. They number nearly 90 separate publications, the principal of which are—*Traité des arbres et arbustes qui se cultivent en France en pleine terre*; *Éléments de l'architecture navale*; *Traité général des pêches maritimes et fluviales*; *Éléments d'agriculture*; *La physique des arbres*; *Des semis et plantations des arbres et de leur culture*; *De l'exploitation des bois*; *Traité des arbres fruitiers*.

DUISBURG, a town of Prussia, at the head of a circle in the government of Düsseldorf, situated at an important railway junction in the country between the Rhine and the Ruhr, and communicating with both rivers by a canal. It has a fine Gothic church—*Salvatorkirche*—of the 15th century, a gymnasium, and an orphan asylum, and is also

the seat of a great Protestant *Diakonenanstalt*, or Deacon's Institute, founded in 1844 by Engelbert, and forming the centre of a large organization for philanthropic action. Its importance, however, is mainly due to the great development of its industry, which deals on an extensive scale with various branches of engineering and the iron manufacture, as well as with cotton—both yarn and cloth—tobacco, sugar, and a number of chemical stuffs, such as alum, soda, and Prussian blue. Probably known to the Romans as *Castrum Deutonis*, and mentioned under the Frankish kings as *Dispargum*, Duisburg early attained the rank of an imperial free town, passed in 1290 to Cleves, and afterwards to Brandenburg, and from 1655 to 1818 was the seat of a university, transferred in the latter year to Düsseldorf. Population in 1871, 30,533.

DUKE (Latin, *dux*), next to the princes and princesses of the blood royal, and the four archbishops of England and Ireland, the highest order and rank of the British peerage. The title of duke was introduced into England when, by a charter dated 17th March 1337, the lordships, castles, lands, &c., constituting the earldom of Cornwall, were erected by King Edward III. into a duchy, and were conferred upon his eldest son Prince Edward of Woodstock, afterwards so well and honourably known as the Black Prince, who thus as duke of Cornwall was the *first* English duke. When, in 1343, he was created to the dignity of Prince of Wales, the Black Prince was invested with a coronet, a gold ring, and a silver rod. And, as duke of Cornwall, he had already been invested with a sword. The second of the English dukes was Henry, earl of Lancaster, Derby, and Leicester, and count of Provence, who in 1351 was created duke of Lancaster.

Of the form and enrichment of the princely coronet of the Black Prince no representation or descriptive record is known to exist; nor is it known whether any distinctive coronet was ever assigned to the prince as the ensign of his ducal rank. As now worn, a duke's coronet has eight golden leaves of a conventional type (commonly called, but without any reason whatever, "strawberry-leaves"), set erect upon a circlet of gold, and having their stalks so connected as to form them into a wreath. In representations, three only of the leaves, with two half leaves, are shown. Of late years this coronet has inclosed, and in representations is shown to inclose, a cap of crimson velvet, surmounted by a rich golden tassel, and lined and guarded with ermine (fig. 1): but, still more recently, this coronet

Fig. 1.

Fig. 2

Ducal Coronets.

is commonly represented, with much better taste, with neither cap or lining of any kind, as in fig. 2. The opinion is prevalent that this distinctive form of coronet appears for the first time placed about the basinet of Prince John of Eltham, the younger brother of Edward III., who died in 1336, in his monumental effigy in Westminster Abbey. That there is no foundation for such a supposed origin of the ducal coronet is evident from the effigy itself; since the decorations of the headpiece and of the rest of the armour are precisely the same, and they also are identical with similar decorations that appear in other effigies of about the same date. The decoration, however, that is carved upon the basinet of Prince John may probably have suggested the crest-coronet, which in the 15th century so frequently

supported knightly crests. It must be added that the basinet in the effigy of Prince John certainly once was encircled by a plain narrow fillet, probably of gold, for the reception of which a channel still appears, slightly sunk in the alabaster immediately below the band of conventional leafage that is carved in low relief. The effigy of the Black Prince himself (1376), at Canterbury, exhibits on the basinet a decorative accessory that may possibly have been the prototype of the leaf-crowned circlet restricted to dukes in later times. From the jewelled band or fillet that encompasses this basinet there rise sixteen leaves, with a second series of the same number of trefoils of much smaller size alternating with the larger leaves, the stalks of the whole being conjoined. These larger leaves differ very slightly from those that are carved upon the armour of Prince John of Eltham, and they are in exact accordance with a favourite form of decorative foliage in general use when the effigy was executed. In his will, Lionel, duke of Clarence, who died in 1368, bequeathed the "*two golden circlets*," with one of which he states that he himself had been "created a duke," while with the other his elder brother, the Black Prince, had been "created a prince." It may be accepted as certain that for a considerable time the coronets of both dukes and earls were decorated rather after an arbitrary taste than in accordance with any established rule. Thus, more than a century after the death of the Black Prince, the coronet of John de la Pole, K.G., duke of Suffolk, has the circlet heightened with fleurs-de-llys alternating with clusters of three small balls. The exact period at which the distinctive enrichments of the coronets of the different orders in the British peerage was determined and established still remains undecided.

In early times, the rank, dignity, and title of duke were directly associated with power, authority, and local possessions, which constituted and were inseparable from his dukedom; but, after a while, these associations gradually became weakened, and at length for the most part they ceased to exist of necessity, so that at the present day the connection between a duke and the locality that gives the title to his dukedom may be very slight indeed.

This same title, duke, is borne still, with their princely rank and title, by the princes of the royal family, as it was in the days of Edward III.; but these royal dukedoms, notwithstanding that they constitute peerages and are hereditary, are created chiefly with a view to connect the members of the reigning house with the great cities or with certain provinces of the realm. The old royal dukedom of York is now so far in abeyance that since the last duke of York died without issue no duke of York has been created. The rival royal dukedom of Lancaster since the accession of Henry IV. has been merged in the crown. The dukedom of Cornwall is held by the heir apparent.

At various periods also, and in different countries, this same title, duke, has been in use to denote certain princes who were the actual sovereigns of small states, or others who, while vassals of some great suzerain, enjoyed in an approximate degree a virtual independence. The term duke, again, was introduced into their English version by the translators of the Old Testament, as a becoming title for certain chieftains and potentates, the Oriental sheiks of a remote antiquity.

A duke in the British peerage, not of royal rank, is styled "Your Grace," and he is "Most Noble." His wife is a "duchess," and she also is styled "Your Grace," and is "Most Noble." All their sons are "lords," and all their daughters are "ladies;" but their eldest son bears his father's "second title," since each of the higher ranks of nobility has one or more of the lower ranks associated with it; thus a duke's eldest son always ranks as a marquis, and generally bears that title. The parliamentary mantle

or robe of a duke is scarlet, and has four doublings of ermine. The royal dukes have coronets as princes. The coronet of a duchess is the same as that of her husband.

The titles arch-duke and arch-duchess, grand-duke and grand-duchess, are in use on the Continent, the former in Austria and the latter in Russia, to distinguish the princes and princesses of the imperial families. The title grand-duke has also been applied to certain of the minor Continental independent princes (C. B.)

DUKINFIELD, a township and local board district of England, in East Cheshire, forming part of the parliamentary borough of STALEYBRIDGE, which see.

DULCAMARA, so named from its taste, at first bitter and eventually sweet, is a drug consisting of the dried young branches of *Solanum Dulcamara*, Bitter-sweet or Woody Nightshade—a woody perennial of the natural order *Solanaceæ*. It has a slender shrubby and climbing stem, flowers in lateral or terminal cymes, with a hypogynous purple corolla, and yellow anthers converging into a cone, and fruit a red, oval, scarlet berry. For medical purposes the branches are collected in autumn when the leaves are shed. Dulcamara contains an alkaloid *solanine*, $C_{43}H_{71}NO_{18}$ (Zwenger and Kind), besides a sweet and bitter principle, *dulcamarine* or *picroglycyon*, and other matters. The drug was formerly supposed to be efficacious in a great variety of complaints. It appears to have some effect on the skin and kidneys, and the infusion is now administered in chronic skin diseases, cachectic conditions of the system, and rheumatic affections.

See D. Cauret, *Des Solanées*, Strasburg, 1864, Garrod, *Materia Medica*, 4th ed. 1874.

DULCIGNO, a town of Turkey in Europe, in the Albaman sanjak of Scutari, occupying a bold promontory on the Adriatic, eighteen miles W.S.W. of the town of Scutari. It has a strong castle, is the seat of a Catholic bishop, and numbers about 8000 inhabitants, who are mainly engaged in agriculture, but also carry on a little ship-building and a certain amount of foreign commerce. The Turkish Olkin, or Olgun, preserves more distinctly the ancient name of *Oleumum*, by which Dulcigno was known to the Romans, who obtained possession of it about 167 B.C. during the war with Gentius, the Illyrian king. In modern history the town is noted for the defeat of the Venetians in 1718; and its inhabitants were long remarkable for their piracies.

DULUTH, a city and lake port of the United States, in the state of Minnesota, advantageously situated at the south-west extremity of Lake Superior, about 150 miles north-east of St Paul. It forms the eastern terminus of the Northern Pacific railroad and the northern terminus of the Lake Superior and Mississippi railroad. A ship canal, 250 feet wide, which has been cut across Minnesota point, gives ready access to the town from the lake. Duluth stands on the side of an acclivity overlooking the lake. It possesses docks, and contains several manufactories. Owing to its position the rise of the town has been very rapid. In 1860 there were not 75 inhabitants, whereas a census in 1875 showed the population to be 5000. It derives its name from Jean Du Luth, a French officer who visited the spot in the 17th century.

DULWICH, a village of England, in the county of Surrey, five miles from London Bridge, remarkable for its college and picture gallery. The manor, which had belonged to the Cluniac monks of Bermondsey, was granted by Henry VIII., in 1541, to Thomas Calton; and his grandson, Sir Francis Calton, sold it in 1606 to Edward Alleyn, whose name is indissolubly associated with the place by his princely foundation. Dulwich College, or, as he quaintly and piously called it, "God's Gift College" (see ALLERS, vol. i. p. 584), was opened with great state on

September 15, 1619, according to the will of Edward Alleyn, who was to be chosen as the first master of St Giles (Camberwell) and St Saviour's (Southwark) schools. In 1663 he obtained a charter of St Giles without Cripplegate, Middlesex. By a series of statutes, and in the days before his death, Alleyn ordained that the parish of St Giles should be for the instruction of 80 boys consisting of the parish and classes:—(1) the twelve poor scholars; the county of inhabitants of Dulwich (who were to be in 1626, a few more); (2) "towne or foreign schollers," who his school should allow as the master and wardens of three distinct classes; (3) it was the founder's intention to establish a public school upon the model of West- taught freely; and, with a liberal provision for university were "to pay suchly shown by the statutes; but he was shall appoint." His grand project was overthrown, and establish a great picture gallery, the educational benefits of minster and St Paul's were restricted to the twelve poor training, is conclusively proved, the foundation was entirely scarcely dead when the Parliament. The government for more than two centuries in 19 governors, of whom God's Gift College was part of Chancery and 8 elected scholars. In 1858, however, the first head of reconstituted by Act of the first also who has not of the college is now vested in the Rev. A. J. Carver, D.D. 11 are nominated by the Court more than £17,000 a by the four parishes already and progressive increase. the reconstituted college, an of management and the borne the name of Alleyn, is, the surplus is divided. The revenue is at present (1877) assigned to the year, with the prospect of a large branch of the After provision for the expenses of the maintenance of the chapel and library, comprises two into four portions, of which three are assigned to the educational and one to the eleemosynary of Parliament. The educational foundation, and he found distinct schools, the "Upper" and the "Lower." The former the curriculum of study, as defined by Act of Parliament, includes, besides ancient and modern languages and mathematics, drawing and designing, civil engineering, physics, chemistry, and other branches of science, in the latter it is similar to that adopted in so-called middle-class schools. The Upper School contained in 1877 nearly 600 boys, and the Lower 160. The buildings of the Upper School are a splendid pile, designed by Mr Charles Barry, in the "Northern Italian style of the 13th century." They are said to form the most commodious and complete, as probably they have proved the most costly, fabric erected for educational purposes in recent times. The main architectural feature is the interior of the great hall, which will compare advantageously with some of the best college halls at Oxford or Cambridge. There are about 25 acres of play-ground and cricket-field included within the boundary fence of the college. Dulwich College possesses one advantage peculiar to itself in its splendid picture gallery, bequeathed to the college by Sir P. F. Bourgeois, R.A., in 1811, with a separate endowment of £520 a year. The pictures most widely known and most highly appreciated are probably the exquisite Murillos and the choice specimens of the Dutch school. The surplus income of the gallery fund is devoted to instruction in drawing and design in the two schools.

See W. Harnett Blanch, *Dulwich College and Edward Alleyn*, 1877.

DUMANGAS, a town of the Philippines, in the island of Panay, near the mouth of the river Jaluar. It is situated in a fertile plain, and deals in rice, trepang, and pina. Population stated at 25,000.

DUMARSAIS, CÉSAR CHESNEAU (1676–1756), a French philologist, was born at Marsailles, July 7, 1676. His father died while he was yet an infant, and his mother,

by her extravagance, dissipated his patrimony. He was educated in his native town by the Fathers of the Oratory, into whose congregation he entered, but feeling the restraints on his liberty too severe, he left it at the age of twenty-five, and repaired to Paris, where he married, and was admitted an advocate in 1704. He soon, however, quitted the bar, separated from his wife, to whom he gave up the little he possessed, and went to reside with the President de Maisons, in the capacity of tutor to his son. He was afterwards successively tutor to the son of Law, the projector, and the son of the Marquis de Baufremont. It was during this last period that he published the results of his grammatical investigations, which were received with great indifference. On terminating his engagement with the Marquis de Baufremont he opened an establishment for education in the faubourg St Victor, which scarcely afforded him the means of subsistence. He strove to eke out his scanty income by contributions to the *Encyclopædia*, but his last years were spent in very straitened circumstances. He died at Paris on the 11th June 1756, at the age of eighty. Dumasais possessed no ordinary talents. His researches are distinguished alike by their accuracy, ingenuity, and depth. As a man, he combined the greatest purity of morals and simplicity of character with a rare degree of manly fortitude in the midst of his misfortunes; yet during the greater part of his life he was left to languish in obscurity, and his merits scarcely attracted any notice until nearly half a century after his death. His works on philosophy and general grammar, however, are worthy of attention. Of these, the best are his *Principes de Grammaire* and his *Histoire des Tropes*. D'Alembert and Voltaire both paid a just and discriminating tribute to the merits of Dumasais. An edition of his works was collected by Duchosal and Millon, and published at Paris in 1797, in seven vols 8vo. In 1804, the French Institute proposed a prize for an *éloge* on Dumasais, which was gained by De Gerando, whose work was published at Paris in 1805, in 8vo. An earlier *éloge* by D'Alembert is to be found in the *Mélanges de Littérature*, and prefixed to the above-mentioned edition of the works of Dumasais.

DUMAS, ALEXANDRE (1802–1870), one of the most remarkable characters that the 19th century has produced, the son of General Dumas and of Marie Labouret, a bookseller's daughter. His father was an officer of remarkable gallantry, who for his dashing exploits had obtained the odd title of the "Horatius Cocles of the Tyrol." He was a creole, the illegitimate son of the Marquis Davy de la Pailletterie, and of Louise Dumas, a black woman of St Domingo. Long after, his grandson was to excite the laughter of Paris by claiming this title, and assuming the family arms. The general had an insubordinate temper, and excited the dislike and suspicion of Napoleon, who sent him back from Egypt to languish in obscurity, and die of disappointment at Villers-Cotterets in the year 1806.

Alexandre Dumas was born on July 4, 1802, at Villers-Cotterets, where he was brought up under the care of an affectionate and pious mother. Some of the most graceful passages of autobiography are to be found in those pages of his memoirs which are devoted to an account of his boyhood, and which present an excellent picture of French country town life. He seems to have been an idle and a troublesome youth, and, though places were found for him with notaries and other functionaries, he could not settle to business. The family means were slender. They were soon almost reduced to poverty; and in the year 1823 Alexandre set off for Paris to seek his fortune, where he was to make such good use of his slender opportunities, that within five years his name became famous. Within a few days of his arrival, an old

friend of his father's, General Foy, obtained a clerk's place for him in the duke of Orleans's establishment, worth only £50 a year, but it seemed a fortune. A friend, D. Lenven, and he now joined their talents in a light farce called *Le Chasse et l'Amour* (produced September 2, 1825). This was succeeded by a dramatic piece, written with the assistance of one of his friends, and called *La Noce et l'Enterrement* (November 21, 1826), known in England as the amusing *Illustrious Stranger*. Meanwhile the visit of Macready and other English players to Paris had introduced him to Shakespeare, and had set him to work on a grand romantic and historical drama which he called *Christine*. The young clerk had the boldness to look forward to having it presented on the boards of the first theatre in France, and, with an energy and spirit that should encourage every friendless aspirant, set every resource he could command at work. Charles Nodding introduced him to Baron Taylor, the literary director of the theatre, who, if we are to credit Dumas, was so enchanted with the work that he accepted it and submitted it to the company at once. It is more probable that, from the rather corrupt fashion which then regulated such matters, the privilege was secured by the influence of the duke of Orleans. But it happened that another *Christine* was supported by even greater influence, and Dumas's had to be withdrawn. In a short time he had written *Henri III*, which was produced (February 11, 1829) with the most extraordinary results. This piece was important as being the first success of the well-known "Romantic school." *Henri III*, it is said, brought its author about £2000. But the revolution of July now broke out and interrupted every literary scheme.

It was, however, welcomed by the creole's son, who flung himself with ardour into the struggle. And here began that double interest in his life, which was as a venture as that of some of his own heroes, and suggests the career of Benvenuto Cellini. He has, of course, made his own share in the exciting scenes of the Three Days as conspicuous as possible; and his expedition to Soissons, and almost single-handed capture of a powder magazine, a general, and officers were heartily laughed at and wholly disbelieved. Allowing, however, for embellishment, it is due to him to say that his narrative seems to be true in the main. He was, however, unlucky enough to have cast his lot with the more violent party, which found itself opposed to the Orleans family, and never recovered their favour, and King Louis Philippe always treated him with a good humoured contempt.

He now returned to his dramatic labours, and produced *Antony* (1831), one of the earliest of those gross outrages on public morality which have helped to make conjugal infidelity the favourite theme of the French drama. But by this time he had found that the slow production of dramas scarcely offered a profitable field for his talents. The successful founding of the *Revue des Deux Mondes* tempted him into trying his skill on historical romances, professedly in imitation of Sir Walter Scott. And this would seem to be the first opening of that seam which was to be worked later with such extraordinary profit. Here he introduced that daring system of working up the ideas of others, which he had already carried out in his dramatic labours, his successful pieces of *Henri III* and *Christine* proving to consist of whole scenes stolen from Schiller and other writers almost without changing a word, though the arrangement of the plot and situations are masterly and original. A piece of his, called the *Tour de Nesle* (produced in 1832), which caused a perfect furore in Paris, led, however, to a more serious charge of plagiarism. In consequence of a duel he was directed to leave France for a time, and set off—in July 1832—on a tour through

3323, 3324, 3325, 3326, 3327, 3328, 3329, 3330, 3331, 3332, 3333, 3334, 3335, 3336, 3337, 3338, 3339, 3340, 3341, 3342, 3343, 3344, 3345, 3346, 3347, 3348, 3349, 3350, 3351, 3352, 3353, 3354, 3355, 3356, 3357, 3358, 3359, 3360, 3361, 3362, 3363, 3364, 3365, 3366, 3367, 3368, 3369, 3370, 3371, 3372, 3373, 3374, 3375, 3376, 3377, 3378, 3379, 3380, 3381, 3382, 3383, 3384, 3385, 3386, 3387, 3388, 3389, 3390, 3391, 3392, 3393, 3394, 3395, 3396, 3397, 3398, 3399, 3400,

by her extravagance, dissipated his patrimony. He was educated in his native town by the Fathers of the Oratory, into whose congregation he entered; but feeling the restraints on his liberty too severe, he left it at the age of twenty-five, and repaired to Paris, where he married, and was admitted an advocate in 1704. He soon, however, quitted the bar, separated from his wife, to whom he gave up the little he possessed, and went to reside with the President de Maisons, in the capacity of tutor to his son. He was afterwards successively tutor to the son of Law, the projector, and the son of the Marquis de Baufremont. It was during this last period that he published the results of his grammatical investigations, which were received with great indifference. On terminating his engagement with the Marquis de Baufremont he opened an establishment for education in the faubourg St Victor, which scarcely afforded him the means of subsistence. He strove to eke out his scanty income by contributions to the *Encyclopædia*, but his last years were spent in very straitened circumstances. He died at Paris on the 11th June 1756, at the age of eighty. Dumasais possessed no ordinary talents. His researches are distinguished alike by their accuracy, ingenuity, and depth. As a man, he combined the greatest purity of morals and simplicity of character with a rare degree of manly fortitude in the midst of his misfortunes; yet during the greater part of his life he was left to languish in obscurity, and his merits scarcely attracted any notice until nearly half a century after his death. His works on philosophy and general grammar, however, are worthy of attention. Of these, the best are his *Principes de Grammaire* and his *Histoire des Tropes*. D'Alembert and Voltaire both paid a just and discriminating tribute to the merits of Dumasais. An edition of his works was collected by Duchosal and Millou, and published at Paris in 1797, in seven vols. 8vo. In 1804, the French Institute proposed a prize for an *éloge* on Dumasais, which was gained by De Gerando, whose work was published at Paris in 1805, in 8vo. An earlier *éloge* by D'Alembert is to be found in the *Mélanges de Littérature*, and prefixed to the above-mentioned edition of the works of Dumasais.

DUMAS, ALEXANDRE (1802–1870), one of the most remarkable characters that the 19th century has produced, the son of General Dumas and of Marie Labonret, a bookseller's daughter. His father was an officer of remarkable gallantry, who for his dashing exploits had obtained the odd title of the "Horatius Cocles of the Tyrol." He was a creole, the illegitimate son of the Marquis Davy de la Pailleterie, and of Louise Dumas, a black woman of St Domingo. Long after, his grandson was to excite the laughter of Paris by claiming this title, and assuming the family arms. The general had an insubordinate temper, and excited the dislike and suspicion of Napoleon, who sent him back from Egypt to languish in obscurity, and die of disappointment at Villers-Cotterets in the year 1806.

Alexandre Dumas was born on July 4, 1802, at Villers-Cotterets, where he was brought up under the care of an affectionate and pious mother. Some of the most graceful passages of autobiography are to be found in those pages of his memoirs which are devoted to an account of his boyhood, and which present an excellent picture of French country town life. He seems to have been an idle and a troublesome youth, and, though places were found for him with notaries and other functionaries, he could not settle to business. The family means were slender. They were soon almost reduced to poverty; and in the year 1823 Alexandre set off for Paris to seek his fortune where he was to make such good use of his slender opportunities, that within five years his name became famous. Within a few days of his arrival an old

friend of his father's, General Foy, obtained a clerk's place for him in the duke of Orleans's establishment, worth only £50 a year, but it seemed a fortune. A friend, De Leuven, and he now joined their talents in a light farce called *Le Chasse et l'Amour* (produced September 22, 1825). This was succeeded by a dramatic piece, written with the assistance of one of his friends, and called *La Noce et l'Enterrement* (November 21, 1826), known in England as the amusing *Illustrious Stranger*. Meanwhile the visit of Macready and other English players to Paris had introduced him to Shakespeare, and had set him to work on a grand romantic and historical drama which he called *Christine*. The young clerk had the boldness to look forward to having it presented on the boards of the first theatre in France, and, with an energy and spirit that should encourage every friendless aspirant, set every resource he could command at work. Charles Nodier introduced him to Baron Taylor, the literary director of the theatre, who, if we are to credit Dumas, was so enchanted with the work that he accepted it and submitted it to the company at once. It is more probable that, from the rather corrupt fashion which then regulated such matters, the privilege was secured by the influence of the duke of Orleans. But it happened that another *Christine* was supported by even greater influence, and Dumas's had to be withdrawn. In a short time he had written *Henri III.* which was produced (February 11, 1829) with the most extraordinary results. This piece was important as being the first success of the well known "Romantic school." *Henri III.*, it is said, brought its author about £2000. But the revolution of July now broke out and interrupted every literary scheme.

It was, however, welcomed by the creole's son, who flung himself with ardour into the struggle. And here begins that double interest in his life, which was as a venturous as that of some of his own heroes, and suggests the career of Benvenuto Cellini. He has, of course, made his own share in the exciting scenes of the Three Days as conspicuous as possible; and his expedition to Soissons, and almost single-handed capture of a powder magazine, a general, and officers were heartily laughed at and wholly disbelieved. Allowing, however, for embellishment, it is due to him to say that his narrative seems to be true in the main. He was, however, unlucky enough to have cast his lot with the more violent party, which found itself opposed to the Orleans family, and never recovered their favour; and King Louis Philippe always treated him with a good humoured contempt.

He now returned to his dramatic labours, and produced *Antony* (1831), one of the earliest of those gross outrages on public morality which have helped to make conjugal infidelity the favourite theme of the French drama. But by this time he had found that the slow production of dramas scarcely offered a profitable field for his talents. The successful founding of the *Revue des Deux Mondes* tempted him into trying his skill on historical romances, professedly in imitation of Sir Walter Scott. And this would seem to be the first opening of that seam which was to be worked later with such extraordinary profit. Here he introduced that daring system of working up the ideas of others, which he had already carried out in his dramatic labours, his successful pieces of *Henri III.* and *Christine* proving to consist of whole scenes stolen from Schiller and other writers almost without changing a word, though the arrangement of the plot and situations are masterly and original. A piece of his, called the *Tour de Nesle* (produced in 1832), which caused a perfect furore in Paris, led, however, to a more serious charge of plagiarism. In consequence of a duel he was directed to leave France for a time, and set off—in July 1832—on a tour through

Switzerland, which suggested to him a series of those odd books of travels made up of long extracts from old memoirs, guide-books, imaginary dialogues, and adventures.

In 1842 he married an actress named Ida Ferrier, who had performed in his plays; but the union was not a happy one, and, after a rather extravagant career, the lady retired to Florence, where she died in the year 1859. Hitherto his success, though remarkable, could not be called European, and he was not to be distinguished from the crowd of French professional *littérateurs*. But in 1844 the famous *Monte Christo* appeared, which may be said to have excited more universal interest than any romance since *Robinson Crusoe* or *Waverley*. The extraordinary colour, the never-flagging spirit, the endless surprises, and the air of nature which was cast over even the most extravagant situations, make this work worthy of the popularity it enjoyed in almost every country of the world. It was followed by the no less famous *Three Musketeers*. These productions were the more remarkable as they were written from day to day for the readers of a newspaper, and thus firmly established the *feuilleton* as a necessary element of French literature. In this, as in other departments where he was successful, Dumas was not original, and only took up the idea of a successful predecessor, Eugène Sue, whose *Jais Errant* had enjoyed much popularity in this shape.

This triumph made him, as it were, irresponsible in the literary world, and suggested to him a series of wholesale operations for supplying the public with books, the history of which makes an extraordinary chapter in literature. He contracted for innumerable stories, each of great length, and to be published at the same time, almost any one of which would be beyond the powers of a single writer. In a single year, 1844 he issued some forty volumes, and later on he engaged himself even more deeply to meet these heavy demands. He began by employing one or two assistants, with whose aid he furnished his two great stories; and it may be said that, with his constant supervision and inspiration, his daily direction, suggestion of incidents, manipulation of the ideas of others, consultations, &c., he might almost fairly claim the credit of having written *Monte Christo* and the *Three Musketeers*. His most valuable assistant was Maquet. Indeed, the chief credit of Dumas's most important stories has been claimed for him, but as he afterwards often tried his powers alone, and with but poor success, it seems probable that his share in Dumas's works was no more than what has been described. But presently the popular writer found that even this form of partnership was too great a tax upon his time, and he began to proceed upon the simpler process of ordering works from clever young writers, to whom he suggested a subject and perhaps a simple outline of treatment—and then issuing their work with his name. Some care in the selection was at first exercised, but later he accepted any stuff that was brought to him—travels, essays, stories—and endorsed them with his name. Indeed a volume could be filled with the odd details and complicated ramifications of this system, which was exposed in the most unsparing fashion by Granier de Cassagnac, Jacquet *alias* "De Mirecourt," and Quérard. Dumas justified his system of appropriating from dead and living authors by a theory of what he called "conquests." "All human phenomena," he says, "are public property. The man of genius does not steal, he only conquers. Every one arrives in his turn and at his hour, seizes what his ancestors have left, and puts it into new shapes and combinations."

In the meantime he was earning vast sums. Leaving the work of composition to his journeymen, he now entered on a new and reckless course, with a view of dazzling his countrymen and gratifying his own Eastern taste. In this view he built a vast theatre for the production of his own

works, and a gorgeous castle at St Germain, on the model of a palace in a fairy tale, on which he lavished every adornment. While these follies were in progress, he succeeded in getting himself attached to the suite of the young duke of Montpensier, then (1846) setting out for Madrid to be married, and received besides a sort of commission from the Government to visit Algeria, with a view to making it popular by a lively account from his pen. He was granted a passage to Oran on board one of the Government mail boats, but, through an awkward misconception, was allowed to divert this vessel from her regular service, and used her for visiting Carthage, Tunis, and other places. On his return there was much scandal, and the ministry was very severely interrogated as to the irregularity of allowing "a contractor for stories" to make so free with public property. It was explained that this was entirely owing to a misrepresentation of the popular writer's. Another rebuff, too, was waiting him, for, having completely neglected his engagements to the various newspapers while making this agreeable tour, he found himself engaged in heavy law-suits with no less than seven journals, including the *Constitutionnel* and the *Presse*. After defending himself in person, a performance that was the entertainment of all Paris, he was cast in damages. This was the beginning of his disasters. His theatre, after opening with one of his pieces which took two nights to perform, fell on evil days, and the revolution of 1848 plunged it into difficulties. In the new scenes he was by no means popular, being repelled from his assiduous attendance on the Orleans family. By this time all his best works had been written; and he was now only to attract attention by some extravagant literary somersault or impudent attempt at "handicapping" the public. He attempted newspapers like the *Horoscope*, of which he would grow tired after a few numbers, but to every article in which he was ready to attach his name. His next escapade was joining Grille (1860), whose messenger and lieutenant he constituted himself, and, in reward for some trifling service, he claimed the appointment of "director of the museum and exploration" at Naples, an office he was presently forced to resign. After this he was reduced to all manner of devices to maintain himself, always borrowing and obtaining money by shifts and pretences which in another could not be called honest. It becomes, indeed, painful to follow the stages in this rapid decay,—to find him reduced to writing "puffs" for tradesmen, to exhibiting himself in shop windows, and to introducing grand schemes to the public which it is impossible to read without hearty laughter. A scandalous infatuation, too, was to be associated with his old age, which last excited the contempt pity of all who knew him. To the last he was full of schemes, devised with the fertility and roscate imagination of a Micawber, and to the last, unfortunately, he was devoted to pleasure. The result was a breaking up of his health, and even a decay of his faculties. When the war of 1870 broke out he was removed from Paris to Puy, near Dieppe, and there affectionately attended by his son and daughter. He died on the 5th of December in the same year. He was even poorer than when he began the world; and the brilliant novelist, who had earned more than £10,000 a year, had hardly a sou left. On the 16th April 1872, when the war was over, his remains were removed to Villers-Cotterets, and interred in presence of the leading *littérateurs* of Paris.

The works that bear Dumas's name are said to amount to some 1200 volumes. His dialogue is entirely his own, full of spirit and dramatic propriety—and this, too, in spite of the temptation, to a man paid by the hue, to "spin out" his matter to the utmost extent. He left about sixty dramas, of which not more than three or four will be remembered, but two, the *Marriage sous Louis XV.* and

Mlle de Belle Isle, belong to the repertoire of the Comédie Française. These will always be listened to with delight. His most popular stories have been mentioned, but even now their undue expansion and interminable development, owing to the necessities of the *feuilleton* system, are found to be serious obstacles to their popularity.

He left a daughter, Madame Petel, who has written a few romances, and a son, the well-known "Alexandre Fils," who, unlike his father, has been distinguished by slow and careful work. He is best known by his romance *La Dame aux Camélias*, which has been translated in every language in which romances are written, and by a number of dramas which deal satirically with the characters, follies, and manners of society under the second empire. (r r)

DUMAS, MATTHIEU, COUNT (1753-1837), a French general and military historian, was born at Montpellier of a noble family, on the 23d November 1753. He joined the army in 1773, and entered upon active service in 1780, as aide-de-camp to Rochambeau commander-in-chief of the army sent to aid the Americans in their war against England. He had a share in all the principal engagements that occurred during a period of nearly two years. Shortly after the capture of Yorktown, in which he took part, he joined the expedition under Vandreuil intended to make an attack on Jamaica. On the conclusion of peace with England in 1783 he returned to France, where he soon afterwards received his commission as major. In 1784 he was sent to explore the archipelago and the coasts of Turkey, a service in which he was engaged for two years, and which he performed with great thoroughness. He was present at the siege of Amsterdam in 1787, where he co-operated with the Dutch against the Prussians. At the Revolution he acted with Lafayette and the constitutional liberal party, whose aim was to effect a complete reform without abolishing monarchy. He was intrusted by the Assembly with the command of the escort which conducted Louis XVI. to Paris from Varennes, where he had been arrested. In 1791 he was appointed to a command at Metz, where he rendered important service in improving the discipline of the troops, and in organizing the first battalion of horse artillery that was formed in France. Chosen a member of the Legislative Assembly in the same year by the department of Seine-et-Oise, he advocated with firmness and eloquence the principles and policy of the constitutional party to which he belonged. In the following year he was elected president of the Assembly. When the extreme republicans gained the ascendancy, however, he became a marked man, and judged it prudent to make his escape to England. Returning after a brief interval under the apprehension that his father-in-law would be held responsible for his absence, he arrived in Paris in the midst of the Reign of Terror, and had to flee to Switzerland to avoid the fate of his friends Barnave and Duport. Dutertre. Soon after his return to France he was elected a member of the Council of Ancients. On the triumph of the extreme revolutionists in 1797, Dumas, being proscribed as a monarchist, made his escape to Holstein, where he enjoyed the hospitality of Count Stolberg. During this exile he wrote the first part of his *Précis des Événements Militaires*, which was published anonymously in monthly numbers at Hamburg in 1800. Recalled to his native country when Bonaparte became first consul, he declined the prefecture of Bordeaux, preferring a military appointment. Intrusted with the organization of the army of reserve at Dijon, he was on the completion of the task appointed chief of the staff to that army. In 1801 he was nominated a councillor of state, and in the same year he was chosen to propose and defend in the Corps Legislatif the formation of the Legion of Honour, of which order he afterwards

(1810) became grand officer. Attached to the household of Joseph Bonaparte, Dumas went in 1806 to Naples, where he became minister of war. On the transfer of Joseph to the throne of Spain, and the accession of Murat to that of Naples, Dumas rejoined the French army, with which he served in Spain during the campaign of 1808, and in Germany during that of 1809. After the battle of Wagram, Dumas was employed in negotiating the armistice, and he was left by Napoleon at Vienna in order to superintend the evacuation of Austrian territory by the French troops. In the disastrous Russian expedition of 1812 he held the post of intendant-general of the army, which involved the charge of the entire administrative department. He shared the horrors of the retreat from Moscow, and the privations he suffered brought on a dangerous illness, from which, however, he recovered after a brief interval of repose at Dantzic. Resuming his duties as intendant-general, he took part in the battles of Lutzen and Bautzen. When the decisive defeat of Leipsic occurred, Dumas, who was stationed with the besieged army in Dresden, was employed to negotiate the unavoidable capitulation, the terms of which, though agreed to by the opposing general, were not ratified by the allied sovereigns. Dumas, who had gone to report the matter to the emperor, was consequently arrested and imprisoned in Hungary until peace was concluded in 1814. On the accession of Louis XVIII. Dumas received several important commissions in connection with the administration of the army. He had the entire confidence of the king, and would have been appointed minister of marine but for the adverse influence of the party that had been in exile during the empire. When Napoleon returned from Elba, Dumas at first kept himself in retirement, but he was persuaded by Joseph Bonaparte to present himself to the emperor, who intrusted him with the task of organizing the National Guards. This brought him into disfavour with the Bourbons, and he was obliged to retire upon half-pay when Louis XVIII. was restored to the throne. He devoted his leisure to the continuation of his *Précis des Événements Militaires*, of which nineteen volumes, embracing the history of the war from 1798 to the Peace of Tilsit in 1807, appeared between 1817 and 1826. A growing weakness of sight, ending in total blindness, prevented him from carrying the work farther, but he translated Napier's *History of the Peninsular War* as a sort of continuation to it. In 1818 Dumas was restored to favour through the influence of Gouvion Saint-Cyr, and admitted a member of the Council of State. In 1828 he was chosen a deputy by the first arrondissement of Paris. After the revolution of 1830, in the events of which he took an active part, Dumas was created a peer of France, and re-entered the Council of State as president of the war committee. He died at Paris on the 16th October 1837. Besides the *Précis des Événements Militaires*, which forms a valuable source for the history of the period of which it treats, Dumas wrote autobiographical reminiscences under the title of *Souvenirs*, which were published posthumously by his son (3 vols 1839).

DUMBARTON, a western county of Scotland, anciently called Leunox or Levenaux, bounded by the river Clyde and its estuary on the S, by Stirlingshire and Lanarkshire on the E, by Perthshire on the N, and by Loch Lomond and Argyllshire on the W. It consists of two parts, which are six miles distant from each other, and are separated by part of Lanarkshire. The western or larger district is about 35 miles long from N W to S E., and 15 broad, the breadth varying from 2 to 13 miles. The eastern district, which is about 12 miles in length from E to W., and 4 in breadth from N. to S, is completely inclosed by the counties of Stirling and Lanark. This detached part, com-

prising the parishes of Cumbernauld and Kirkintilloch, belonged to Stirlingshire till the earl of Wigton, whose property it was, became heritable sheriff of Dumbartonshire, and annexed it to this county, which, as a whole, contains 270 square miles, or 172,677 statute acres, and is divided into 12 parishes. The county is in shape a crescent, having a convex coast-line of 35 miles, formed by the Clyde on the south for 15, and Loch Long on the west for 20 miles. Along its eastern side for a distance of 24 miles stretches Loch Lomond, the "queen of Scottish lakes," studded with small islands, which number 30 in all, and most of which, with about two-thirds of the shore, are in Dumbartonshire. There are other fresh-water lakes in the county, but they are of a minor description. The Gare Loch is an arm of the sea about six miles long by one broad, and forms with Loch Long the peninsula of Roseneath, nearly detaching it from the mainland. Besides the Clyde, the only river of any note which can be said to belong to this county is the Leven, the outlet of Loch Lomond, which, flowing for six miles through a fine valley, joins the Clyde at Dumbarton Castle. The mountainous districts are marked by numberless cascades and lesser streams, falling for the most part into Loch Lomond, of which the chief are the Falloch, Laveruglas, Douglas, Finlas, Fruin, &c. The Kelvin, which skirts the eastern border, drains the detached portion of the county. About two-thirds of Dumbartonshire are hilly and mountainous. The most elevated regions are in the west and north-west, between Loch Long and Loch Lomond, and to the north of Loch Lomond. Ben Vorlich, in the extreme north, attains an elevation of 3092 feet, and Finlart, on Loch Long, is 2500 feet high. While this mountainous character prevails in the north of the county, in the eastern detached district and along the Clyde and the Leven it is lowland—marked, however, by the rising of abrupt eminences such as the hills of Kilpatrick and Cardross, and the rocks of Dumbarton and Dumbuck. In scenery it is unsurpassed in Scotland, not only for what it embraces but for the magnificent and extensive views which it commands. The climate varies with the character of the county, but is on the whole salubrious, though much more humid than in many parts of Scotland. The prevailing winds are from the west and south-west, but easterly winds are frequent in the spring months. Frosts are seldom severe, and, except on the mountains, snow never lies long. In the southern districts of the county Old Red Sandstone stretches from Roseneath to Loch Lomond; limestone is found in the higher grounds of Kilpatrick, Dumbarton, and Row; the hills of Dumbuck and Kilpatrick and Dumbarton Rock are composed of trap, while mica slate, quartz, and talc principally constitute its northern formations. Clay-slate is likewise found, and has been wrought with success at Luss, Camstradden, and Roseneath. Coal measures also exist, and there are pits for working coal in several districts. Ironstone is found in considerable quantities in connection with limestone in the parishes of Kirkintilloch and Cumbernauld.

The arable lands of Dumbartonshire, which extend chiefly along the Clyde and the Leven, and are composed of rich black loam, gravelly soil, and clay, are divided into farms ranging from 30 to 300 acres, and in some cases to 700 or 800 acres. From the proximity to Glasgow and other large towns, the farmers have the double advantage of good manure and a ready market for all kinds both of stock and produce, and, under the stimulus of this, great progress has been made. Special attention has been given to the construction of farm buildings, the erection of fences, and the use of proper draining, as well as to the rearing of cattle and the management of dairy stock, principally of the Ayrshire breed. Black-faced sheep and black cattle are pastured on the hilly lands, and Cheviot sheep and

Ayrshire stock on the low grounds. In 1876 Dumbartonshire had 1717 horses, 13,153 cattle, 71,202 sheep, and 911 pigs. Oats and wheat are grown in considerable quantities; large crops of potatoes are raised, turnips, barley, and beans are also grown. In 1876 there were 9862 acres under corn crops, of which 7930 were under oats and 1140 under wheat, while 4443 under green crops. On the banks and islands of Loch Lomond there are some yew trees of large size, and evidently of a very great age. There are few large estates in the county; the largest being Rossdhu (Sir James Colquhoun, Bart.), 67,041 acres, Strathleven (Mrs Ewing), 9180, Roseneath (duke of Argyll), 6799, and Cumbernauld (Hon. Cornwallis Fleming), 3520. The whole number of landowners having one acre and upwards is 706, possessing 152,968 acres, of the annual value of £251,134.

The banks of the Leven, whose waters as well as being constant are singularly soft and pure, have long been celebrated for their bleaching establishments, dye-works, and print-works. Bleaching was carried on in the Vale of Leven upwards of 150 years ago. The printing of cotton began at Levenfield in 1768, and has for some time been the chief manufacturing industry in Dumbartonshire. There are carried on with great success at Upper and Lower Levenbank Works, located within half a mile of Loch Lomond, the dyeing and printing of Turkey red cloth and yarn; at Dalmoonach, the different processes in calico-printing; and at Ferryfield, Croftingea, and Dilchipp the various departments of the general business are conducted on a large scale. At Milton, in West Kilpatrick, the first factory for machine weaving was erected, and here existed, a century ago, a bleaching and calico printing establishment. At Duntocher, in the same parish, cotton-spinning has been carried on from the beginning of the century, and so extensively as to take rank as the second manufacturing industry in the county. In the town of Dumbarton there are extensive ship-building yards, engine-works, foundries, tanneries, and breweries. At Dalmuir extensive works for the repair of the dredging plant belonging to the Clyde Trust were erected by the trustees in 1867, costing £25,000. A large patent slip for taking on the dredgers used on the Clyde forms part of these works, at which three steam forge-hammers are in constant operation. In 1850 a line of railway, already completed from Bowling to Dumbarton, was extended up the Vale of Leven to Balloch. In 1858 the Glasgow railway to Helensburgh was opened, running through Bowling, Dumbarton, and Cardross, and supplying, with the steam communication on the Clyde and the lochs, abundant facilities for every kind of traffic to all parts of the county. The Forth and Clyde Canal, begun in 1768 and opened for traffic in 1775, passes through Dumbartonshire for more than 16 miles, and is carried over the valley of the Kelvin by an aqueduct. At Bowling there is a harbour with quays, forming a tidal basin of 8½ acres.

The county is somewhat rich in antiquities, connected both with the period of the Roman occupation and with that of the aboriginal inhabitants of Scotland. The wall of Antoninus runs along the north of the eastern part and through the south-east corner of the main district to Kilpatrick. Remains of Roman workmanship have been found at Duntocher and in the parish of Cumbernauld, as well as at the castle. The Caledonians, Picts, &c., are commemorated by rude forts and tumuli here and there; and there are several remains of old baronial castles. Rob Roy's district lies to the north; the clans had encounters in Glenfruin; and the county is associated with the heroic Wallace and Bruce, the latter having built a residence at Cardross, in which he died. In modern times, the first steam navigation company in Britain was formed at Dumbarton in 1815, Henry Bell, from whose designs the first steamer built

on the Clyde, "The Comet," was constructed, and who indeed was the first to put into operation the idea of employing steam for navigation purposes, lived at Helensburgh, where he died in 1830. A monument to him was erected near Bowling. The celebrated ship-building firm of Napier & Sons had its origin in a smith's foundry business at Dumbarton.

Several important watering-places, including Helensburgh, Kilcreggan, Roseneath, &c., are situated in Dumbartonshire. The other principal towns and villages are Kirkintilloch, Alexandria, Duntocher, Bonhill, Renton, Dalmuir, Kilpatrick, Cardross. The leading gentlemen's seats are Rosdhu (Sir James Colquhoun, Bart.), Roseueath, (duke of Argyle), Garcube House (Sir George Campbell), Tiltchewan Castle (J. Campbell), Bonhill Castle, and Shandon (now a hydropathic establishment), built by the late Robert Napier.

The county sends one member to Parliament. Population in 1801, 20,710, in 1841, 44,296, in 1871, 58,857.

DUMBARTON, a royal parliamentary and municipal burgh and seaport-town of Scotland, capital of Dumbartonshire, is situated at the confluence of the rivers Clyde and Leven, 14 miles north-west from Glasgow. It is a very ancient place, and is said to have been once the capital of a kingdom of the Britons in the vale of the Clyde. Aleclud, "the rock upon the Clyde," was the name of this ancient capital of the Strathclydenses, but whether it was situated on the site of the present town, or confined within the precincts of the castle, cannot be exactly ascertained. The site had previously been used as a naval station by the Romans, who called it Theodosia. At a subsequent period, Dumbarton was the capital of the earldom of Lennox, but was given up by Earl Maldwyn to Alexander II, by whom it was erected into a royal burgh in the year 1221, and declared to be free of all imposts and burgh taxes. It afterwards received other charters from succeeding monarchs, and finally it obtained a confirmation of the whole from James VI. Among other privileges conferred was that of levying customs and dues on all vessels on the Clyde from the Kelvin to the head of Loch Long; and ships within these bounds had to pay duties at Dumbarton. "Officers dues" on foreign vessels coming into the Clyde were also levied. In 1700 these rights were transferred to Glasgow by a contract, but were subsequently vested in a special trust created by successive Acts of Parliament. The town is principally built upon the eastern bank of the Leven, which almost encircles it, and is chiefly composed of one main street, lying in a semi-circular form round the head or west end of the peninsula and parallel to the river. A good stone bridge of five arches, 300 feet long, connects the town with Bridgend, a suburb on the western side of the Leven. The waters of the Leven form the harbour. For seventy years the staple trade of Dumbarton was the manufacture of crown glass, commenced in 1777 and discontinued after the abolition of the glass duty. As many as 300 hands were employed in the business. But for many years its principal trade has been ship-building, and particularly the construction of iron steamers. By situation the most "natural" port on the Clyde, Dumbarton has the distinction of originating in Britain the formation of steam navigation companies. In 1815 a joint-stock company was formed in Dumbarton to run a steamer from that town to Glasgow, and their steamer, the "Duke of Wellington," was built by James McLachlan in Dumbarton. The next steamer was built by William Denny in 1820, from which date the ship building of the town may be said to have started. But it was not till 1844, on the application of iron to the purposes of ship-building, that the trade assumed the important proportions to which it was raised by the firm of Denny and by others. The Dennystoun Forge

Company, which is amongst the largest and most unique in Great Britain, both as respects the building itself and the machinery employed, was opened in 1855. Extensive harbour improvements were entered upon in 1852, and successfully carried out. In 1874 the total tonnage of iron vessels launched in Dumbarton amounted to 32,000, in 1875 to 37,000, in 1876 to 17,500. Some of the vessels built in Dumbarton are among the most magnificent employed in the British trade. The General Police Act has been in operation in Dumbarton since 1855. In 1857 the sanction of Parliament was obtained to a bill for extending the municipal boundaries so as to include West Bridgend. The embankment of the Broad Meadow, a project which had been entertained for 250 years, was accomplished in 1859, securing for the town a considerable tract of agricultural land and 20 acres of recreation ground. Since 1860 the burgh has been supplied with water drawn from the Long Craigs. A fine cemetery, a mile from the town, was formed in 1854, and the old Dumbarton parish churchyard has been closed by authority since 1856. The disadvantage Dumbarton long laboured under of having access to the river steamers merely by ferry boats is now obviated by a pier recently constructed from the foot of Dumbarton Rock, at a cost of from £8000 to £9000.

The situation of Dumbarton Castle is eminently picturesque. The buildings composing the fort are perched on the summit of a rocky mount, shooting up to the height of 206 feet sheer out of the alluvial plain on the east side of the mouth of the river Leven. To the east of the castle there are rocky eminences on the verge of the Clyde, of a similar form, though less isolated. The Rock of Dumbarton measures a mile in circumference at the base. It diminishes in breadth near the top, which is cloven into two summits of different heights. The rock is basalt, and has a tendency to columnar formation. Some parts of it have a magnetic quality. The fortress, naturally strong, possesses several batteries, which command a very extensive range. According to a provision in the Treaty of Union, the defences are kept in constant repair, and a garrison is maintained in the castle.

The affairs of the burgh are managed by a provost, 2 bailies, and 16 councillors. The county and burgh buildings are good. Dumbarton joins with Port-Glasgow, Renfrew, Rutherglen, and Kilmarnock in returning a member to Parliament. In 1871 the population amounted to 11,404. (D. M.)

DUMDUM, or DAMDAMÁ, a town and cantonment in British India, at the head of an administrative subdivision in the district of the Twenty-four Pergunnahs, in the presidency of Bengal, with a station on the Eastern Bengal railway, $4\frac{1}{2}$ miles N.E. of Calcutta, in $22^{\circ} 37' 53''$ N. lat. and $88^{\circ} 28' 1''$ E. long. It was the head-quarters of the Bengal artillery from 1783 to 1853, when they were transferred to Meerut as a more central station; and its possession of a cannon foundry and a percussion-cap factory procured for it the half-jocular name of the Woolwich of India. The barracks—still occupied by small detachments—are brick-built and commodious, and among the other buildings are St Stephen's Protestant church, a Roman Catholic chapel, a European and native hospital, a largo bazaar, and an English school. The population in 1872 amounted to 5179, of whom 1201 were Mahometans, 1053 Christians, and 2586 Hindus. The males numbered 3414, the females 1765. It was at Dumdum that the treaty of 1757 was signed, by which the nawab of Bengal ratified the privileges of the English, allowed Calcutta to be fortified, and bestowed freedom of trade; and in 1857 it was the scene of the first open resistance of the sepoys to the use of greased cartridges.

DUMFRIES, one of the three Scottish border counties, lies in an elliptical form on the north side of the Solway Firth, its other boundaries being Lanark, Peebles, and Selkirk on the N., Roxburgh on the E, Ayr and Kirkcudbright on the W., and Cumberland on the S. Its greatest length is fully 50 miles, its breadth 32, its circumference 190, and the area is 1103 square miles or 702,953 acres. The coast-line on the Solway measures 21 miles. Towards this arm of the sea the county slopes down from a high mountain range, by which it is incircled on the north, the intermediate pace being extremely irregular, lofty hills alternating with wide stretches of table land or rich fertile holms, and in other instances the surface looking like a vast undulating mass that by some natural process had suddenly become fixed and rigid. Among the leading features of the county are the three dales by which it is cleft from north to south, and through which run the rivers that give name to them, the Nith, Annan, and Esk. Overlooking these rise numerous elevations, the highest being Whitecoomb in the east, 2695 feet; Hartfell in the north, 2651 feet, Queensberry, also in the north, 2285 feet, which gives to the duke of Buccleuch his secondary title, and the title of marquis to a branch of the house of Douglas; and Ettrick Pen, 2269 feet, the latter standing sentinell over an extensive district.

The Nith is the chief river of the county. Starting from its mountain cradle near Dalmellington, in Ayrshire, it takes a south-westerly sweep, watering the old burgh of Sanquhar, at the head of Nithsdale, and further down the modern village of Thornhill, near which stands the ducal castle of Drumlanrig. As the river proceeds it passes on the one hand Dalswinton, where Patrick Miller made his first fruitful experiments in steam navigation, and on the other the acres of Ellisland, which Robert Burns turned over with his plough. At Auldgirth Bridge, near Blackwood, the dale narrows considerably, then it expands till around and below the burgh of Dumfries it appears as a spacious plain, with gentle acclivities or bolder elevations rising on every side. The Nith is swelled by numerous streams at various stages, its latest and largest acquisition being the Cluden, the confluence taking place about a mile above Dumfries, and the absorbing river reaching the Solway about eight miles below that burgh, its whole course measuring about 50 miles.

An upland spot, where the counties of Lanark, Peebles, and Dumfries converge, gives birth to three streams, according to the popular saying,

"Annan, Tweed, and Clyde
All arise from one hillside."

The first-named river, after a rapid canter from its highland source, five miles above Moffat, receives several tributaries a little south of that town, then proceeds at a leisurely pace down the dale, which, narrowed at first by rocks or ridges, expands into a fertile basin termed "the Howe of Annandale," studded with hamlets and spangled by the nine lochs of Lochmaben,—that venerable royal burgh, which claims to have been the birth-place of King Robert Bruce, and the prosperous town of Lockerbie occupying conspicuous places on the western and eastern banks, other rivulets, including the Dryfe (flowing past the scene of a fierce clan battle fought between the Maxwells and Johnstones in 1675), giving increased volume to the stream below Bruce's burgh, the valley narrowing again as the water grows wider and deeper. When little more than a mile from the sea it passes Annan, the second town in the county, its entire length being nearly 40 miles.

During about a mile of its course the Esk divides Dumfriesshire from Cumberland; starting from the Selkirkshire frontier it flows southward past the baronial town of Langholm, and, after being a Scottish stream to the extent

of 30 miles, it enters English ground, waters Longtown, describes a westward curve, and then falls like its two sister streams into the Solway, its entire course extending to about 40 miles.

Besides the lakes in Annandale already referred to, Loch Skene, lying under the shadow of Whitecoomb hill, 1300 feet above sea-level, is the only one of consequence, its water finds an outlet by leaping over a rocky height of 300 feet, forming a cascade termed the Gray Mare's Tail. Another small but exceedingly picturesque waterfall in Morton parish is called Crichepe Linn.

The chief mineral waters of the county are those of the well at Moffat, and another about five miles distant, called Hartfell Spa, situated in a cleft of the hill from which it takes its name. The former are reckoned beneficial for chronic gout, rheumatism, and liver complaints; and the latter acts as a mild astringent and powerful tonic. Owing to the great repute of these waters, and the romantic scenery of the surrounding district, Moffat during summer and early autumn becomes a favourite and fashionable place of resort. A small chalybeate at Brown, on the Solway, possesses considerable virtue, and is rendered interesting from the circumstance that it was partaken of by Burns during his last illness, though without avail.

Generally speaking the climate is mild and salubrious, with a mean temperature of 45° Fahr, the average rainfall supplying sometimes more than enough of moisture. The soils are chiefly gravel or sandy loam and clay, except where river and estuary have formed rich alluvial tracts. At no very distant date it was roughly computed that there were 86 square miles of arable land lying along the sea coast, 322 miles chiefly upland, and 598 miles mountainous yielding nothing but heather and game; but by the application of bone manure, draining, planting, and green crop husbandry, all this is changed, no fewer than 213,784 acres being under the plough—even the huge expanse of Lochiar moss, lying in the parishes of Tinwald, Dumfries, and Torthorwald, becoming by degrees less of a reproach to the agricultural enterprise of its proprietors, though much of the surface of the county still wears a pastoral aspect drawn from one of its chief rural industries, sheep-breeding. In 1876 there were 49,975 acres under corn crops, of which 48,292 were oats and 546 wheat; 25,669 were under green crops, of which 20,747 were turnips, and 63,762 were in grass under rotation. These figures differ little from those for 1873, except that 1231 acres were then in wheat. With abundance of coal at the two extremities—Sanquhar and Canonbie; with limestone at Kilhead, Closeburn, and Barjarg; with lead mines at Wanlockhead, the produce of which when undergoing refinement yields a large percentage of silver; with gold dust and even nuggets of that metal in the same district, but now no longer searched for systematically, as they were with considerable success in the 16th and 17th centuries; with sandstone quarries in various quarters, with woollen mills at Langholm; with numerous manufactures centring in the county town; with some little sea-borne traffic, and with good salmon fisheries in the Nith, along the Carlaverock shore, and at Annan Water-Foot on the Solway,—the county itself is still essentially an agricultural one, and as such it takes high rank.

Early in the 18th century the district breeders of Galloway cattle began to send stock to the south; and, before the current century was far advanced, some 15,000 head of heavy cattle were annually driven from Dumfriesshire and Galloway to the English markets. Forty years ago the number had increased to 20,000, their value on an average being at least £200,000. For some years past Ayrshire dairy cattle and shorthorns have superseded the Galloways on most farms of the county, and its trade in live stock generally has considerably decreased. Few store cattle are

exported, they being mostly grazed a year or two and fed off; and similar treatment is given to numerous short-horn yearlings and two-year-olds that are imported from Ireland. In 1876 the entire cattle in the county numbered 53,778 head, the sheep 493,020, the horses 7390, the pigs 14,413,—these returns varying little from those of 1873, except as regards sheep, which amounted that year to 513,849. The sheep trade of Dumfriesshire, which is of comparatively recent origin, is now of great extent. Cheviots predominate, the frugal, black-faced breed still occupying the higher sheep walks, while half-bred lambs, the produce of Cheviot ewes crossed by Leicester or other long-wooled rams, are fattened on the richer pasture yielded by low-lying farms, supplemented by turnips in winter, and are thus made ready for the butcher when fifteen months old. For nearly a hundred years pig-feeding has occupied a place in the rural economy of the county. A sum of £50,000 represented its annual trade in pork about sixty years ago. Influenced by large imports of bacon from America, the curing of carcases has of late decreased. In 1876 the number sold in the public markets of the county was under 8000, the value of which, allowing for those disposed off privately, would not exceed £45,000; a few years back the annual value ran from £70,000 to £75,000. As regards quality and flavour, the Dumfriesshire hams still maintain the high character they have long held in the English markets.

Three leading highways, one in each valley, with numerous branch roads, intersect the county. It possesses also ample railway communication,—the Glasgow and South-Western line, completed in 1850, extending through Nithsdale and Lower Annandale, and, soon after passing Gretna Green (famous in days of yore for its matrimonial celebrations), crossing the little border river Sark; and the Caledonian line, completed in 1849, traversing Moffatdale and Upper Annandale, and also a portion of England as far as Carlisle.

In a Parliamentary Blue Book (1874) the acreage of the county is given at 676,971, and its yearly value (1872) at £595,511, 17s., the owners numbering 4177, of whom 886 possessed more than one acre each, the value per acre being 17s. 7d. as compared with 20s. for all Scotland. From the valuation roll for 1876 we learn that the chief proprietor, the duke of Buccleuch and Queensberry, owns 255,514 acres, yielding an annual revenue of £97,840. The names of other leading proprietors, with their extent of land and incomes from it, are—Mr J. J. Hope Johnstone of Annandale, 64,079 acres, with a rental of £28,684; earl of Mansfield, 14,342 acres, £15,938; marquis of Queensberry, 13,243, £13,982; Mrs Villiers and Viscountess Cole of Closeburn, 13,560, £11,658; Sir John Heron Maxwell of Springkell, 13,391, £9023; Mr R. Jardine of Castlemilk, 17,064, £9339; Sir F. J. W. Johnstone of Westerhall, 7714, £7932; and Lord Herries, 5814, £6537. Population of county in 1861, 75,878; in 1871, 74,784.

Dumfriesshire during the Roman occupation formed part of the province of Valentia, which lay between the walls of Hadrian and Antonine, the British tribes occupying it being termed the Selgovæ. In course of time they were dispossessed by other Celts, the Scots-Irish; but the aboriginal Britons shared with the latter, and with the numerous Saxons and the few Normans of a later day, in being the progenitors of the existing inhabitants; and on them lasting memorials remain in the names of rivers, mountains, and headlands, most of which are British, "the nomenclature of the earliest colonists of the county thus remaining unchanged by the conflicts of race or the flight of ages." Down to the death of David I., Nithsdale and some other portions of the district were still to a large extent Celtic in their people and institutions; after that king's reign we begin to read of its historical families, some of whom are still its leading landowners—of its Maxwells, Douglasses, Kirkpatricks, Johnstones, Bruces, Ballols, Comyns, Scotts, Carlyles, Jardines, Murrays, and Crichtons.

Of all the primitive inhabitants numerous memorials still exist

in the form of druidical remains, British motes and camps, Roman roads and camps, Anglo-Saxon relics, the chief of the latter being the Runic monument at Ruthwell, which tells the story of the Cross in characters as old as the days of the Heptarchy. As the county is also replete with "chiefless castles breathing stera farewells," and other time-worn tokens of by-gone ages, it presents a rich field for archaeological research.

DUMFRIES, beautifully situated on the left bank of the Nith, about eight miles from the Solway Firth, is the capital of the county just described.

The irregular yet decided progress of the town can be traced through the Middle Ages, and more recently till our own day, when it wears an attractive and flourishing aspect. A serious check was given to its prosperity by a visitation of cholera, which cut off more than 500 of its inhabitants in 1832. Since a copious supply of good water was obtained from a neighbouring loch, and other sanitary improvements were introduced, the salubrity of the burgh has been fairly established, and its size and trade—promoted also by its railway intercourse and the establishment of the tweed manufacture—have greatly increased. Few Scotch provincial towns have gone forward with such a gigantic stride during the last thirty years, and its steps in advance have been especially remarkable during the latter half of that period, as shown chiefly by the bustle of its business streets, the formation of new thoroughfares, and the numerous suburban villas which now environ the old burgh proper.

From time immemorial the town has possessed a great weekly cattle market, which, though reduced since 1848 by the establishment of competing markets, and the substitution of sheep for cattle on many surrounding farms, is still second to none on the north side of the border. The average number of cattle sold on the Sands during five years ending 1872 was nearly 14,000 yearly; in 1876 the number was 18,413, besides 6844 sold at the auction marts. Vast herds are also sent direct south from the railway station. A still larger trade is now done in sheep, the average number offered for sale during five years ending 1872 being 37,000, while 29,980 were sold at market in 1876, and 42,958 by auction. There is also a weekly market for pork, beginning in November and ending about the end of March.

Among the special industries of Dumfries, clog-making and basket-making have long occupied an important place; its traffic in timber has grown to be immense; a hundred acres of nursery ground help to beautify the town, and supply material for an extensive trade in seeds, flowers, and other plants; the conversion of skins into hides and leather gives labour to about 150 hands; while nearly the same number are engaged at iron works. More extensive than any of these is the hosiery manufacture, which, dating a century back, now gives employment to about 480 hands (including warehousemen), the goods produced ranking as the best in Scotland, and next to those of Hawick in extent. Prior to 1847, however, the prosperity of Dumfries depended much on its position as the capital of a rich rural district, which it still is; but soon after that date it began to bulk largely as a manufacturing town in connection with the tweed trade; and to its development the growth of the burgh in size and opulence is principally due. The principal firm, that of Walter Scott and Sons, usually employs about 1400 workers, with 400 looms and 30,000 spindles. Nearly all the business traffic to and from Dumfries is now carried on by rail, the vessels belonging to the port numbering only two or three, and its revenue—burdened by heavy interest on a sum borrowed to erect a large sea-dyke, which has been of little benefit—is insufficient to cover the expenditure.

The origin of two places of worship in connection with the Established Church (St Mary's and Greyfriars') is noticed below; a third, St Michael's, is a stately fabric

dating from 1746. Before the lower interior was resented in 1869, it contained a pew which Burns and his family occupied. The poet's remains rest under a magnificent mausoleum in the surrounding churchyard; and besides this paramount distinction the cemetery is richer with monumental erections than that of any other provincial town in the United Kingdom. Among the other ecclesiastical buildings are three Free churches, three belonging to the United Presbyterians, two to the Congregationalists, one each to the Wesleyan, the Scottish Episcopal, the Catholic Apostolic, and the Roman Catholic, while two other denominations—the Baptists and Evangelical Union—are also represented. Dumfries has three newspapers, two of them published twice a week and one weekly. It has long been able to boast of a well-equipped grammar-school—the Academy. The town possesses its full share of benevolent institutions. Its oldest one, Moorhead's Hospital, erected in 1753, gives accommodation to decayed householders. A hospital for the reception of persons suffering from disease or accident has been in existence since 1778, under the name of the Dumfriesshire and Galloway Royal Infirmary, but the building now used as such, an imposing edifice in the Northern Italian style, was only opened a few years back; 398 patients were treated in 1876, at a total outlay of £2137. Crowning an eminence situated a little southward of the town stands a noble building resembling a Greek cross; this is the Crichton Royal Institution for lunatics, due to the munificence of Dr James Crichton of Friars' Carse, whose bequest of £100,000 was applied in erecting and partly endowing the asylum. Since it was opened, nearly forty years ago, it has been considerably enlarged, and also supplemented (in 1848) by the Southern Counties' Asylum for pauper inmates chiefly; usually the patients number about 500, nearly a third, as middle and upper class patients, being housed in the older portion of the establishment. The old infirmary building is now used as a commercial academy connected with the Marist Brotherhood, and dedicated to St Joseph. In it about 70 youths receive education; belonging to the establishment there is a novitiate adjoining the Roman Catholic chapel, where 14 members of the order are under training for missionary service at home or abroad. Several of the banking establishments possess a fine appearance, but the county buildings in Buccleuch Street (Scottish baronial in design), Greyfriars' Church fronting the head of High Street (Pointed Gothic), and the new infirmary are the most imposing edifices within the burgh. It has a theatre royal, opened in 1792, which was almost entirely reconstructed at a cost of £3000 in 1876, and its interior is now, size considered, as handsome as that of any similar place of entertainment throughout the kingdom. There is no object in the town that can vie with Devorgilla's Bridge as regards archaeological interest. Built of stone about 1280, it had no equal at that period in Scotland, though the popular story which assigns to it thirteen arches is belied by indisputable documents which show that they never numbered more than nine. A second stone bridge was built in 1793-5, at an expense of about £5000; and a small iron foot bridge, which cost nearly £2000, was opened on the closing day of 1875. The associations of Dumfries with Burns, however, and the memorials it possesses of the national bard, draw to it more travellers annually than all its other attractions—scenic, antiquarian, or social.

The town council consists of 25 members, including a provost, 3 bailies, a dean of guild, and a treasurer. Four other royal burghs combine to form a parliamentary constituency with Dumfries, namely, Annan, Kirkcudbright, Sanquhar, and Lochmaben—these, "The Five Carlus" of Burns's ballads, being represented by one member. In

1861 the population within the royalty was 12,347; in 1871 it had increased to 13,701. As a parliamentary burgh Dumfries includes Maxwelltown on the opposite bank of the Nith, its population as such amounting in 1871 to 18,826.

History—The precise circumstances of the origin of Dumfries are but imperfectly known, but the prevailing opinion is that a fortlet built by the Selgovæ Britons formed the nucleus of the town, an hypothesis that is supported by its name, which, according to Chalmers, is resolvable into two Gaelic terms signifying a castle among the brushwood. The oldest existing charter is one granted by Robert II., dated 1395. Made a royal burgh by William the Lion, Dumfries thereby acquired important privileges; and another stimulus to its prosperity was supplied when Devorgilla, daughter of Alan, lord of Galloway, connected that province with the town by building a stone bridge over the Nith. It was the son of that munificent lady, John Bahol, whom Edward I. of England selected as heir to the Scottish throne from the numerous competitors for it who placed their claims at his disposal. During the troubles that ensued, Nithsdale and Galloway supported Bahol, and on his withdrawal from public life they for the most part favoured the pretensions of his nephew John, the Red Comyn, as opposed to those of Robert Bruce, who drew considerable support from his patrimonial estates of Annandale.

Dumfries figured much in the wars of the period. Whilst the great border castle of Carlaverock was being besieged by an army under the command of King Edward in 1300, the town was visited by him personally, and, as we learn from the *Wardrobe Account*, he lodged with a body of Franciscan friars in a house built for them by Devorgilla, and partly maintained by dues levied at the bridge which ended its existence to her liberality. Six years afterwards, when Edward had smitten down all opposition to his ambitious designs, the monastery which he had visited became the scene of a deed which led to the overthrow of them all. On the 10th of February 1306 Bruce and Comyn were brought together in the streets of the ancient burgh. As they entered the monastery in company, Bruce charged his rival with treachery, the latter denied the accusation, and the next moment was stabbed to the heart, Kirkpatrick rushing in to "mak siccar" or complete the deed of slaughter which the lord of Annandale had begun. The blow by which the Red Comyn perished in the house erected by his pious grandmother broke all amicable intercourse between the homicidal baron and the English king; and thereafter Bruce became thoroughly committed to the national cause, of which he had been previously but a questionable friend. A modern ecclesiastical edifice, St Mary's Church, occupies a site mournfully associated with the war of independence.—Sir Christopher Seton, husband of Bruce's sister Christiana, having been there executed by order of Edward I. After peace was restored, the sorrowing widow built upon the spot a little chapel, which her royal brother endowed with a hundred shillings sterling per annum in order that masses for the soul of the deceased should be said in it "for ever." Another church, Greyfriars', stands on the site of the old castle of Dumfries, which exchanged owners half a dozen times at least during the same troublous period,—its sufferings by siege or storm indicating but too truly the sad experiences of the town itself; and for nearly 250 years afterwards, the proximity of the burgh to the western border exposed it to wasting raids from the English side, carried on sometimes by freebooting parties, and not seldom also by more formidable hosts with higher objects in view than the burning of the place or the plunder of its inhabitants,—these hostile visits, with their retaliatory forays southward, terminating at last in 1551. The long close connection of Dumfries with the heroic yet turbulent Douglasses proved on the whole more hurtful to it than advantageous. Bound up for several generations quite as intimately with the Maxwells of Carlaverock and Terregles, the town experienced alternate "weal and woe" from the protracted feuds of that family with the Annandale Johnstones.

When the Union with England was under debate, the provost of Dumfries, as its representative in the Scottish Parliament, voted against the measure, and the Articles of Union were publicly burned (Nov. 20, 1706) by a party of Cameronians at the market cross, with the enthusiastic approval of the populace. About nine years afterwards the inhabitants were threatened with a hostile visit from Viscount Kenmure, but they manifested such a bold front that the Jacobite chief acted on Falstaff's maxim, "Discretion is the better part of valour." Less vigilant during the next rebellion, they allowed the town to be peacefully occupied by the young Pretender, who, converting No. 6 of the tenement now used as the Commercial Hotel into a little palace, held high state there for three days towards the close of December 1745. In order at once to recruit his own exchequer and punish the burgh for its loyalty to the house of Hanover, the prince demanded a tribute of £2000 in money; also 1000 pairs of shoes for his kilted followers, whose foot-gear had nearly vanished during their forlorn journey from the south; and, as if he had been *de facto* king, he levied the

excise and appropriated all the moneys possessed by the local Government officials. Influenced by a false alarm, "Bonnie Charlie" made a hurried departure, having first received £1100 of a levy, and carrying with him hostages for the rest. Some years afterwards the burgh was reimbursed by the state for the money contribution, the whole of which had been paid, and for the shoes actually delivered, 225 pairs, the compensation amounting to £2848.

In 1264 Alexander III planned an expedition to the Isle of Man at Dumsries. The town was visited at subsequent periods by James IV, James V, by the beautiful daughter of the latter monarch, Queen Mary, and by Mary's son, the "British Solomon." On the arrival of James VI, 3d August 1617, he was sumptuously entertained by the magistrates in a house that was known as "The Painted Hall," afterwards he presented the incorporated trades, seven in number, with a tiny "war-engine," the celebrated Silver Gun, the competition for which encouraged the practice of musketry among the craftsmen, and constituted a great septennial festival, the characteristics of which are finely nurrored in a well-known poem by John Mayne, though the wapenschaw itself has not been held since 1831. (W M'D.)

DUMONT, JEAN, a well-known publicist, was born in France in the 17th century, the precise date being unknown. He followed the profession of arms; but, not obtaining promotion so rapidly as he expected, he quitted the service and travelled through different parts of Europe. He stopped in Holland with the intention of there publishing an account of his travels. But in the interval, at the request of his bookseller, he wrote and published several pamphlets, which were eagerly sought after, owing to the unceremonious manner in which he treated the ministry of France. This freedom having deprived him of all hope of employment in his own country, he thought of forming a permanent establishment in that where he resided, and accordingly commenced a course of lectures on public law. The project succeeded far beyond his expectations; and some useful compilations which he published about the same period made him favourably known in other countries. The emperor appointed him his historiographer, and some time afterwards conferred on him the title of Baron de Carlsrουν. He died at Vienna in 1726, at an advanced age. Dumont wrote with facility, but his style is deficient in vigour and correctness; his works, however, contain a great number of documents valuable for history.

The following is a list of the works published by Dumont:—1. *Voyages en France, en Italie, en Allemagne, a Malte, et en Turquie*, Hague, 1699, 4 vols 12mo, 2. *Mémoires Politiques pour servir à la parfaite intelligence de l'histoire de la Paix de Ryswick*, Hague, 1699, 4 vols 12mo, 3. *Recherches modestes des causes de la présente Guerre, en ce qui concerne les Provinces Unies*, 1713, 12mo; 4. *Récueil de Traités d'alliance, de paix, et de commerce entre les Rois, Princes, et États, depuis la Paix de Munster*, Amsterdam, 1710, 2 vols 12mo, 5. *Soupirs de l'Europe à la vue du projet de paix contenu dans la harangue de la reine de la Grande-Bretagne*, 1712, 12mo, 6. *Corps Universel Diplomatique du Droit des Gens, contenant un Récueil des Traités de paix, d'alliance, etc., faits en Europe, depuis Charlemagne jusqu'à présent*, Amsterdam, 1626, and following years, 8 vols fol, continued after Dumont's death by J. Rousset; and 7. *Batailles gagnées par le Prince Eugène de Savoie*, Hague, 1723. Dumont was also the author of *Lettres Historiques contenant ce que se passe de plus important en Europe*, 12mo. This periodical, which was commenced in 1692, and two volumes of which appeared annually, Dumont conducted till 1710, from which time it was continued by Basnage and others until 1728. The earlier volumes are much prized.

DUMONT, PIERRE ÉTIENNE LOUIS (1759–1829), a political writer celebrated chiefly for his literary connection with Mirabeau and Jeremy Bentham, was born on the 18th July 1759 at Geneva, of which his family had been citizens of good repute from the days of Calvin. Shortly after his birth his father died, leaving a widow and four children wholly unprovided for. But the widow, though placed in such destitute circumstances, found means to send Étienne to the college of Geneva, where he distinguished himself both by his ability and by his independent spirit. In a short time he not only defrayed the cost of his own education, but even contributed to the support of the family, by acting as *répétiteur*, or private tutor to his comrades

Having completed his academical course, he took clerical orders; and in the year 1781 he was chosen one of the pastors of the city, where his talents as a preacher soon attracted general notice, and gave promise of his becoming one of the most brilliant and persuasive of pulpit orators. But the political troubles which disturbed Geneva in 1782 suddenly turned the course of his life into a different channel. He belonged to the liberals or democrats, and the triumph of the aristocratical party, through the interference of the courts of France and Sardina, made residence in his native town impossible to him, though he was not among the number of the proscribed. He therefore became a voluntary exile, and went to join his mother and sisters at St Petersburg, a city to which many Genevese had resorted. In this he was probably influenced in part by the example of his townsman Lefort, who was the first tutor, minister, and general of the czar. At St Petersburg he filled for eighteen months with great acceptance the office of pastor of the French church. In 1785 he removed to London, Lord Shelburne, then a minister of state, having invited him to undertake the education of his sons. It was at the house of Lord Shelburne, afterwards marquis of Lansdowne, where he was treated as a friend or rather member of the family, that he became acquainted with some of the most illustrious men of the country, amongst whom may be mentioned Fox, Sheridan, Lord Holland, and Sir Samuel Romilly. With the last of these he formed a close and enduring friendship, which had an important influence on his life and pursuits.

In 1788 Dumont visited Paris in company with Romilly. During a sojourn of two months in that city he had almost daily intercourse with Mirabeau, and a certain affinity of talents and pursuits led to an intimacy between two persons diametrically opposed to each other in habits and in character. On his return from Paris Dumont formed that connection with Jeremy Bentham which exercised a powerful influence over his future opinions, and, as it were, fixed his career as a writer on legislation. Filled with admiration for the genius of Bentham, and profoundly impressed with the truth of his theory, and the important consequences to which it immediately led, Dumont made it one of the chief objects of his life to recast and edit the writings of the great English jurist in a form suitable for the ordinary reading public. This literary relationship was, according to Dumont's own account, one of a somewhat peculiar character. All the fundamental ideas and most of the illustrative material were supplied in the manuscripts of Bentham; Dumont's task was chiefly to abridge by striking out repeated matter, to supply lacunæ, to secure uniformity of style, and to improve the French. The following works of Bentham were published under the editorship of Dumont:—*Traité de la Législation* (1802), *Théorie des peines et des Récompenses* (1811), *Tactique des Assemblées législatives* (1815), *Preuves Judiciaires* (1823), and *Organization Judiciaire et Codification* (1828).

In the summer of 1789, that season of promise and of hope, especially to a Genevese exile, Dumont suspended his labours in England in order to proceed to Paris along with his friend Duroverai, ex-attorney-general of the republic of Geneva. The object of the journey was to obtain through Necker, who had just returned to office, an unrestricted restoration of Genevese liberty, by cancelling the treaty of guarantee between France and Switzerland, which prevented the republic from enacting new laws without the consent of the parties to this treaty. The proceedings and negotiations to which this mission gave rise necessarily brought Dumont into connection with most of the leading men in the Constituent Assembly, and made him an interested spectator, sometimes even a participator, indirectly, in the events of the French Revolution.

The same cause also led him to renew his acquaintance with Mirabeau, whom he found occupied with his duties as a deputy, and with the composition of his journal, the *Courier de Provence*, in which he was assisted by Dnoverai, Clavière, and other Genevese patriots. For a time Dumont took an active and very efficient part in the conduct of this journal, supplying it with reports as well as original articles, and also furnishing Mirabeau with speeches to be delivered or rather read in the assembly, as related in his highly instructive and interesting posthumous work entitled *Souvenirs sur Mirabeau* (1832). In fact his friend George Wilson used to relate that one day, when they were dining together at a *table d'hôte* at Versailles, he saw Dumont engaged in writing the most celebrated paragraph of Mirabeau's address to the king for the removal of the troops. He also reported such of Mirabeau's speeches as he did not write, embellishing them from his own stores, which were inexhaustible. But this co-operation, so valuable for Mirabeau, and so self-devoted on the part of Dumont, was destined soon to come to an end; for, being attacked in pamphlets as one of Mirabeau's writers, he felt hurt at the notoriety thus given to his name in connection with a man occupying Mirabeau's peculiar position, and resolved to return to England, which he accordingly did in 1791.

In the eventful years which followed he continued to live chiefly at Lansdowne House, or at Bowood, where the most remarkable men of Europe were frequent guests. Latterly, he formed an intimate friendship with Lord Holland, whom he had known from childhood, and he became a member of the society of familiar friends, the habitual visitors at Holland House, where, during many years, celebrated guests were welcomed of every country, party, religion, and of every liberal profession or station. In 1801 Dumont travelled over various parts of Europe with Lord Henry Petty, afterwards marquis of Lansdowne, and brought back a fresher acquaintance with the mental occupations of the Continental nations, from whom England had for years been widely separated. But Dumont had then opened a new course of more serious occupations, in the editorship of the works of Bentham already mentioned. In 1801 he published the *Traité de la Législation*, the first fruits of his zealous labours to give order, clearness, and vivacity to the profound and original meditations of Bentham, hitherto praised only by a very few patient readers, and but little better known, even by name, to the English than to the European public. In 1814 the restoration of Geneva to independence induced Dumont to return to his native place, and he soon became at once the leader and ornament of the supreme council. He devoted particular attention to the judicial and penal systems of his native state, and many improvements on both are due to him. At the time of his death, he was on the eve of proposing a complete code of law, by which he fondly hoped to make the legislation of Geneva an example to Europe. He died at Milan when on an autumn tour of relaxation in October 1829, in the seventy-first year of his age.

DUMONT D'URVILLE, JULES SÉBASTIEN CÉSAR (1790–1842), a French navigator, born in the town of Condé sur-Noireau, in Normandy. The death of his father, who before the revolution had held a judicial post in Condé, devolved the care of his education on his mother and his maternal uncle, the Abbé De Croisilles. Failing to pass the entrance examination for the Ecole Polytechnique, he went to sea in 1807 as a novice on board the "Aiglon," and soon attracted the attention of the captain, Maignon, by his studious disposition. During the next twelve years he gradually rose in his profession, and continued through all its multitudinous vicissitudes to increase his scientific and linguistic acquisitions—botany, entomology, English, German, Spanish, Italian, and even Hebrew and Greek

were added to the more professional branches. In 1820, while engaged in a survey of the Mediterranean under Captain Gauthier of the "Chevette," he was fortunate enough to recognize the Venus of Milo in a Greek statue recently unearthed, and to secure its preservation by the report he presented to the French ambassador at Constantinople. A wider field for his energies was furnished in 1822 by the exploring expedition of the "Coquille" under the command of his friend Duperrey; and on its return in 1825 his services were rewarded by promotion to the rank of *capitaine de frégate*, and he was intrusted with the control of a similar enterprise. The "Astrolabe," as he now named the "Coquille," left Toulon on April 25, 1826, and reached Marseilles again on 25th of March 1829,—having traversed the South Atlantic, coasted the Australian continent from King George's Sound to Port Jackson, laid down various parts of New Zealand, and visited the Fiji Islands, the Loyalty Islands, New Caledonia, New Guinea, Amboyna, Van Diemen's Land, the Caroline Islands, Celebes, and Mauritius. Promotion to the rank of *capitaine de vaisseau* was bestowed on the commander in August 1829, and in August of the following year he was charged with the delicate task of conveying the exiled King Charles X. to England. His proposal to undertake a voyage of discovery to the south polar regions was discouraged by Arago and others, who criticised the work of the previous expedition in no measured terms; but at last, in 1837, all difficulties were surmounted, and on 7th September he set sail from Toulon with the "Astrolabe" and its convoy "La Zélée." On 15th January 1838 they sighted the Antarctic ice, and soon after their progress southwards was blocked by a continuous bank, which they vainly coasted for 300 miles to the east. Returning westward they visited the South Orkney Islands and part of the New Shetlands, and discovered Joinville Island and Louis Philippe's Land, but were compelled by scurvy to seek succour at Talcahuano in Chili. Thence they proceeded across the Pacific and through the Asiatic archipelago, visiting among others the Fiji and the Pelew Islands, coasting New Guinea, and circumnavigating Borneo. In 1840, leaving their sick at Hobart Town, Tasmania, they returned to the Antarctic region, and on the 21st of the month were rewarded by the discovery of Adélie Land, in 140° E. of Greenwich. The 6th of November found them at Toulon. D'Urville was at once appointed rear-admiral, and in 1841 he received the gold medal of the Société de Géographie. On the 8th of May 1842 he was killed along with his wife and son in a railway accident near Meudon. Though many of his observations are no longer regarded as trustworthy on account of the defective character of the instruments employed, he made many important additions to various departments of scientific geography, and his natural history collections were especially valuable. His principal works are—*Enum. plantarum quas in insulis Archipel. aut littoribus Ponti Euxini*, &c., 1822; the *Histoire du voyage* (5 vols. of the 22) in the great work on the "Astrolabe" expedition in 1826–1829, the first part of the *Histoire du voyage* (10 vols. of the 23) in the series devoted to the expedition from 1837 to 1840, *Voyages autour du Monde résumé général des voyages de Magellan*, &c., 1833, 1844.

See Berthelot's *éloge* in *Bull. de la Soc. de Géogr.* 2d ser. t. xix; Matterer, *Notice nécrologique*, &c., Paris, 1842; Isidore Lebrun, "Biographie," &c., in *Annales Maritimes*, t. lxxviii, De Barins, *Vie, voyages*, &c., Paris, 1844, Lesson, *Notice histor.*, Rochefort, 1846.

DUMOURIEZ, CHARLES FRANÇOIS (1739–1823), general of the French republican army, was born at Cambrai in 1739 of a respectable family of Provence. His father was a commissary of the royal army, and had acquired some celebrity as a poet, and from him young Dumouriez received his earliest instructions. His studies were con-

tinued at the college of Louis-le-Grande for three years. In 1757, his father having been attached to the army under D'Estrées about to invade Hanover, he accompanied him to Mauberge, and served with distinction during the Seven Years' War. In 1763 he attained the rank of captain; but, in consequence of a reform reducing the numbers of the army, he retired with a small pension and the cross of St Louis. He afterwards received a subordinate situation in the secret service.

On his return from a pedestrian tour in Italy, he addressed a memorial to the Duc de Choiseul, urging him to embrace the cause of the Corsicans against the Genoese; and a public audience which he had with the minister on the subject led to a violent altercation, the result of which was a *lettre de cachet* which forced Dumouriez to leave France. But the expedition which he had advised being afterwards resolved on, Choiseul made him an honourable public reparation, and appointed him quartermaster-general of the troops. The political conjunctures of the times offered an unlimited scope for his fertility in diplomatic expedient, and he mingled in all the intrigues of the age. In 1770 he was sent on a secret mission to Poland with the view of neutralizing the efforts of Catherine II., and succeeded in securing fifty senators for the cause of independence, effected a unity of action among the confederates, and disciplined a militia; but, when there was some appearance of the resurrection of Poland being effected, Choiseul lost his place, owing to the machinations of the Duc d'Aiguillon and Madame Du Barry, and Dumouriez was recalled to Paris. He was soon, however, sent back on a similar mission by D'Aiguillon. He endeavoured to assist the revolutionists in Sweden, and to raise troops in the Hanse towns to menace Stockholm, but this was contrary to the views of the French cabinet; and the Duc d'Aiguillon, having discovered his project, had him arrested and imprisoned in the Bastille for six months. He was afterwards sent to the castle of Caen, from which he was not released until the accession of Louis XVI.

Dumouriez had naturally little inclination to resume the connection with foreign politics which had proved so dangerous, and he accordingly devoted his attention to the internal economy of his own country. He wrote a memoir on the great importance that might be given to the harbour of Cherbourg, one result of which was that he was appointed governor of the place in 1778.

In 1788 Dumouriez was promoted to the rank of major-general. When the revolutionary movement began he pronounced in favour of political reform without breaking with the court. The connections which he held with the leading men of the Girondist party greatly advanced his political career. At the opening of the second legislative assembly he was appointed minister for foreign affairs in place of Delessart, but he held the position for only three months. During his short tenure of office he exerted himself to the utmost in reforming abuses, and in introducing the greatest economy into every department.

He held for one month the office of minister of war after the dismissal of his colleagues Roland, Servan, and Clavière. At length his own resignation followed, which increased his popularity. When the troops of the coalition advanced against France, he was appointed to the command of the army of the north as lieutenant-general under Marshal Luckner. He made a determined stand against the advance of the allies, which was decisively checked by the defeat inflicted on them at Valmy on the 20th September 1792. This was followed by a campaign in the Austrian Netherlands, in which Dumouriez was uniformly successful, until he was signally defeated by Coburg in the battle of Neerwinden in January 1793. The execution of Louis had estranged him from the republican party, and, when in

consequence of his defeat he was recalled by the Convention and threatened with a charge of treason, he sought refuge in the camp of the Austrians, accompanied by the Duc de Chartres (afterwards Louis Philippe) and his brother.

Lost without hope of return to his native country, Dumouriez wandered a long time an exile in Brussels, England, Switzerland, Germany, Denmark, and St Petersburg. At last in 1804 he took up his permanent residence in England, where the Government conferred on him a pension of £1200 a year. In 1814 and 1815 he endeavoured to procure from Louis XVIII the baton of a marshal of France, but was refused. He died at Turville Park, near Henley-on-Thames, on the 14th March 1823. His memoirs, written by himself, were published at Hamburg in 1794. An enlarged edition, under the title *La Vie et les Mémoires du Général Dumouriez*, appeared at Paris in 1822. Dumouriez was also the author of a large number of political pamphlets.

DUNABURG, a town of European Russia, at the head of a district in the government of Vitebsk, for the most part on the right bank of the Dwina, 12 miles south-east of Riga, in 55° 53' N. lat. and 31° 29' 9" E. long. It consists of four portions—the main-town or fortress, the old suburb, the new suburb, and on the left bank of the river the village of Grive. The fortress is of the first class, and forms the most important point in the line of defences of the Dwina, the floating bridge across the river is protected by a splendid *tête-de-pont*. Among the public buildings are five churches, a Roman Catholic chapel, a Jewish synagogue, a gymnasium, and a theatre; and among the industrial establishments several tanneries and breweries, a saw-mill, a flour-mill, brick and tile works, and limekilns. Its position on the railway between Warsaw and St Petersburg, and its double means of communication with Riga, render the town an important commercial centre, especially for the trade in flax, hemp, tallow, and timber. There are weekly markets and two large annual fairs. Of the 25,674 inhabitants registered in 1861, 7561 were Jews, 3994 Roman Catholics, and 690 Protestants. In 1873 the total population was 29,613.

Dunaburg was originally founded in 1273 by the Livonian Knights of the Sword, about 12 miles further down the river than its present site, at a spot still known as the Old Castle or *Starus Zamok*. In 1559, along with other portions of the territory belonging to the order, it was mortgaged by the grand-master Gothard Kettler to Sigismund Augustus king of Poland for the sum of 700,000 guildens, and two years afterwards it became the centre of the new Polish province of Infland. Captured in 1576 by Ivan the Terrible, it was again restored to Poland, and in 1582 Stephen Bathori transferred the fortress to its present site. In the 17th century it was held now by the Swedes and now by the Russians, and in 1656 it ran the risk of losing its old name for that of Borisoglebsk, bestowed by the emperor Alexis Michaelovitch. Finally incorporated with Russia in 1772, it received its present administrative rank in 1777, and its recognition as a first-class fortress in 1811. In July 1812 the *tête-de-pont* was vainly stormed by Oudinot, but a few weeks afterwards the town was captured by Macdonald.

DUNBAR, a royal and parliamentary burgh and seaport of Scotland, in the county of Haddington, situated on an eminence near the mouth of the Firth of Forth, 29½ miles E.N.E. of Edinburgh by the North British railway. The ruins of the castle, the remains of the Grey Friars' monastery founded in 1218, and a mansion house of the Lauderdale family, are the principal objects of historical interest. The parish church is a fine building of red sandstone, with a tower about 107 feet in height, which forms a well-known landmark to seamen, it dates only from 1819, but occupies the site of what was probably the first collegiate church established in Scotland, and still preserves the large marble monument of Sir George Home, created earl of Dunbar and March by James VI. in 1605. The town-hall, the assembly rooms, the public schools, the

mechanics' institute and subscription library, and the benevolent institutions require no special notice. The principal source of wealth is the herring fishery, which fosters an extensive curing trade; but ship-building is also carried on, and there are several iron foundries, breweries, and distilleries, as well as a large paper-mill in the vicinity. The harbour, formerly small and shallow, has been greatly enlarged and improved in the course of the present century, at the joint expense of the town and the Fishery Board, but the entrance is rendered somewhat dangerous by the number of craggy islets and sunken rocks. Dunbar unites with Haddington, Jedburgh, Lauder, and North Berwick in returning a member to Parliament. In 1875-6 the value of real property was £11,832. Population in 1871, 3320.

The castle of Dunbar, mentioned as early as 856, from the strength of its position became of great importance as a bulwark against English invasion, and a town grew up under its protection, which was created a royal burgh by David II. It was captured by Edward I, who defeated the forces of Baliol in the neighbourhood of the town in 1296, it afforded shelter to Edward II on his flight from Bannockburn; and it was besieged in 1337 by the English under Montague earl of Salisbury, but was successfully defended by Black Agnes of Dunbar, countess of March and a member of the Douglas family. In the 15th century it was chosen as her usual residence by Joanna Beaufort, the widow of James I of Scotland; and in the 16th it served on several occasions as a retreat for the unfortunate Queen Mary. An Act of Parliament had been passed in 1488 ordering the demolition of the castle, but it was reserved for the Regent Murray to effect its destruction in 1567. A battle popularly known as the "race of Dunbar" was fought in 1650 between Cromwell and Leslie, and resulted in the total rout of the Scotch.

DUNBAR, WILLIAM, one of the most distinguished of the early poets of Scotland, is supposed to have been born about 1460. Comparatively little is known about his personal history, but, from an allusion in one of his poems, he seems to have been a native of Lothian.¹ In his fifteenth or sixteenth year he was sent to the university of St Andrews, where he received the degree of B.A. in 1477, and that of M.A. in 1479.

Of the events of his life for nearly twenty years after this we possess little information. He mentions, however, in his poems that he had been employed as a preaching friar of the order of St Francis, and as such had made good cheer in every flourishing town in England had ascended the pulpit at Derton and Canterbury, and had crossed the sea at Dover, and instructed the inhabitants of Picardy. He also mentions that this mode of life compelled him to have recourse to many a pious fraud, from whose guilt no holy water could clear him. After this he appears to have entered the service of James IV, by whom he was sent on numerous embassies to foreign princes.² In 1491 he was residing at Paris, most likely in connection with the Scottish embassy there. The knowledge of the Continent he thus obtained must have had considerable influence in imparting greater strength and energy to his poetical conceptions.

In the year 1500 Dunbar obtained from the king a yearly pension of £10, until he should be promoted to one of greater value. In 1501 he went to England with the ambassadors sent to conclude the negotiations for the marriage of the young King James with the Princess Margaret, daughter of Henry VII. During the festivities on this occasion Dunbar was styled "the Rhymer of Scotland," and received from Henry a present of £6, 13s 4d in December, and a similar sum in January of the subsequent year. On his return to Edinburgh a sum of £5 was paid to him in addition to his salary. In honour of this

marriage Dunbar composed his well known poem, *The Thrissil and the Rois*, another in honour of the city of London, and several others in which he described the personal attractions of the young queen. After this he lived much at court writing poems, although at the same time he hoped to obtain preferment in the church.

In 1504 he first performed mass before the king, whose offering on that occasion was £4, 18s, a larger sum than that usually paid on the occasion of a priest's first mass. In 1507 his pension was augmented to £20, and three years afterwards it was raised to £80, to be paid during his life, or until he should be promoted to a benefice of £100 or more. In 1511 he seems to have been in the train of Queen Margaret when she visited the northern part of Scotland, as one of his poems, descriptive of her reception at Aberdeen, is evidently written by an eye-witness.

After the disaster of Flodden, in 1513, Dunbar's fortunes seem to have changed, and no further mention of him occurs as receiving pension. That he may have obtained church preferment is quite possible, but the probability is, that the early death of the king, and the unpopularity of the queen and the little influence she had after her marriage with the earl of Angus, may have led to neglect of Dunbar in his old age. His poems contain many allusions to the unequal division of the world's goods. He was alive in 1517, as in that year he wrote a poem on the occasion of the Regent Albany passing into France, in which he laments the distracted state of public affairs in Scotland.³ He is supposed to have died about the year 1520, when he had attained his sixtieth year.

The poems of Dunbar, "the darling of the Scottish muse," are about a hundred in number, for the most part of no great length. *The Thrissil and the Rois*, written, as before remarked, on the occasion of the marriage of James IV., is an allegory in which he describes the amity between England and Scotland in consequence of that event. *The Golden Targe* is a moral poem of great power of imagery, in which the ascendancy of love over reason is shown to be general—the golden shield of reason being insufficient to ward off the shafts of Cupid. *The Trea Maryut Wemen and the Wedo*, a tale in which the poet overhears three females relating their experiences of married life, is an imitation of Chaucer's *Wife of Bath*. *The Freiris of Berwik*, a tale, is also in the Chaucerian style. *The Flying of Dunbar and Kennedy* is perhaps the most obscure of his poems, though it seems to have been very popular, and frequently imitated in the 16th century. Several of his smaller poems show a quick appreciation of peculiarities of character, but some of them—such as the tournament, or *Justis betuix the Tailyeour and Sowtar*—though ludicrous, are very coarse. In one called *A Dance in the Queenis Chalmer*, he describes himself as one of the performers:—

Thain cam in Dunbar the makkar,
On all the flure thair was naue frakkar,
And thair he dautit the dirrye dantoun,
He hoppit like a pilbe wantoun
For luif of Musgraiffe, men tellis me,
He trippet quhile he tint his pantoun,
A mirrear dance mycht na man see.

Another *Dance*, that of the *Sevin Deidlie Synnis*—in which Mahoun, prince of devils, is described as holding a carnival with Pride, Ire, Envy, Covetousness, Idleness, Treachery, Gluttony, each with a train of followers, while a company of fiends stand by enjoying the sport, encouraging

² There is considerable doubt about the period of Dunbar's death, as the poem relative to the Regent Albany may have been attributed to him by mistake. Mr Laing has conjectured that he may have accompanied King James, and been killed along with him in the battle of Flodden, where so many ecclesiastics perished. The volume of the accounts of the Treasurer from 1513 to 1515, which might have settled this and other important points, has been lost.

¹ *Flying with Kennedy*, line 110.

² In a poem to the king he reminds him that he had been employed not only in France, England, and Ireland, but also in Germany, Italy, and Spain. (Noted by Laing, vol. i. app. 263.)

the performers with various hot applications—is as extravagant a piece as can well be conceived. In contrast, however, he wrote several poems of a religious character, *e.g.*, *Off the Nativity of Christ*; *Off the Passoun of Christ*; *Off the Resurrection of Christ*, and *The Maner of Passyng to Confessioun, &c*

More fortunate than Douglas and some of the earlier Scottish poets, Dunbar had the satisfaction of seeing his principal works in print. *The Thrissil and the Rois*, *The Golden Targe*, *The Flying with Kennedy*, and the ballad of *Lord Barnard Stewart* were printed by Chepman and Myllar in 1508, and are the first specimens of typography that issued from the Scottish press.¹ Several of his poems were preserved in the Asloane MS, written in 1575, the Bannatyne MS 1568 preserved in the Advocates' Library, the Maitland MS, in the Pepysian Library, and the Reidpeth MS in the University Library, Cambridge. Of these detached poems some appeared in collections edited by Allan Ramsay, John Pinkerton, and Lord Hailes, in the course of the last century, but at length the works of Dunbar were collected and published in 1834 by Dr David Laing (2 vols. 8vo, with a supplement, 1875), having a biography and valuable illustrative notes. In 1873 a minute analysis of the language of Dunbar was published at Bonn by Dr Johannes Kaufmann of Elberfeld.

DUNBLANE, a market-town in Perthshire, Scotland, formerly the seat of a bishopric, pleasantly situated on the banks of the Allan. Its cathedral is one of the few specimens of Gothic architecture in Scotland which escaped destruction at the Reformation. It is said to have been founded in 1142, and was nearly rebuilt by Clemens, bishop of Dunblane, about 1240. The whole building is of the Early Pointed style of architecture, except the tower, which is Early Norman. The cathedral remains unroofed, with the exception of the choir and chapter house. The choir has been used as the parish church since the Reformation, but lately alterations have been made by the removal of a thick partition wall and galleries, and the erection of a light partition wall containing two windows, the gift of Sir William Stirling Maxwell, Bart. One of the bishops of Dunblane was Leighton, who left his library, which is still preserved, to the clergy of the diocese. About a mile and a half to the east of the town is Sheriffmuir, where a battle was fought in 1715 between the earl of Mar, in the command of the troops of the Pretender, and the royal forces under the duke of Argyll. Dunblane has no charter. A sheriff court and commissary courts are held there, and there is a large district prison. There is a market on Thursdays, and several fairs are held annually. At Cromlix, a mile and a half to the north, there are two mineral springs, and not far from the town an elegant hydropathic establishment has been erected. The population in 1871 was 1921.

DUNCAN, ADAM, FIRST VISCOUNT (1731–1804), an illustrious naval commander, was born July 1, 1731, at Lundie, in Forfarshire, Scotland. After receiving the rudiments of his education at Dundee, he was in 1746 placed under Captain Haldane, of the "Shoreham" frigate, and in 1749 he became a midshipman in the "Centurion." In 1755 he was appointed second lieutenant of the "Norwich," a fourth-rate; but on the arrival of that ship in America, whither, with the rest of Keppel's squadron, it had convoyed General Braddock's forces, he was transferred to the "Centurion." Once again in England, he was promoted to be second lieutenant of the "Torbay," 74, and after three years on the home station he assisted in the attack on the French settlement of Gorée, on the African coast, in which he was slightly wounded. He returned to England as first lieutenant of the "Torbay," and in 1759 was made a commander, and in 1761 a post-captain. His vessel, the

"Valiant," was Commodore Keppel's flag-ship in the expedition against Belleisle in that year, and also in 1762, when it took an important part in the capture of Havana. In 1778, on the recommencement of war with France, Captain Duncan was appointed to the "Suffolk," whence before the close of the year he removed to the "Monarch," one of the Channel Fleet. On January 16, 1780, in an action off Cape St Vincent, between a Spanish squadron under Don Juan de Langara and the British fleet under Sir George Rodney, Captain Duncan in the "Monarch" was the first to engage the enemy, and in 1782, as captain of the "Blenheim," he took part in Lord Howe's relief of Gibraltar. From the rank of rear-admiral of the blue, received in 1789, he was gradually promoted until, in 1799, he became admiral of the white. In February 1795 he hoisted his flag as commander-in-chief of the North-Sea fleet, appointed to harass the Batavian navy. Towards the end of May 1797, though in consequence of the wide-spread mutiny in the British fleet, he had been left with only the "Adamant," 50, besides his own ship the "Venerable," 74, Admiral Duncan proceeded to his usual station off the Texel, where lay at anchor the Dutch squadron of fifteen sail of the line, under the command of Vice-Admiral De Winter. From time to time he caused signals to be made, as if to the main body of a fleet in the offing, a stratagem which probably was the cause of his freedom from molestation until, in the middle of June, reinforcements arrived from England. On October 3 the admiral put into Yarmouth Roads to refit and victual his ships, but, receiving information early on the 9th that the enemy was at sea, he immediately hoisted the signal for giving him chase. On the morning of the 11th De Winter's fleet, consisting of four seventy-fours, seven sixty-fours, four fifty-gun ships, two forty-four-gun frigates, and two of thirty-two guns, besides smaller vessels, was sighted lying about nine miles from shore, between the villages of Egmont and Camperdown. The British fleet numbered seven seventy-fours, seven sixty-fours, two fifties, two frigates, with a sloop and several cutters, and was slightly superior in force to that of the Dutch. Shortly after mid-day the British ships, without waiting to form in order, broke through the Dutch line, and an engagement commenced which, after heavy loss on both sides, resulted in the taking by the British of eleven of the enemy's vessels. When the action ceased the ships were in nine fathoms water, within five miles of a lee shore, and there was every sign of an approaching gale. So battered were the prizes that it was found impossible to fit them for future service, and one of them, the "Delft," sank on her way to England. In recognition of this victory, Admiral Duncan was, on October 21, created Lord Viscount Duncan of Camperdown, and baron of Lundie, with an annual pension of £3000 to himself and the two next heirs to his title. In 1800 Lord Duncan withdrew from naval service. He died August 4, 1804.

DUNCAN, THOMAS (1807–1845), a distinguished Scottish portrait and historical painter, was born at Kinclaven, in Perthshire, May 24, 1807. He was educated at the Perth Academy, and afterwards began the study of the law, which, however, he speedily abandoned for the more congenial pursuit of art. Commencing his new career under the instruction of Sir William Allan, he early attained distinction as a delineator of the human figure; and his first pictures established his fame so completely, that at a very early age he was appointed professor of colouring, and afterwards of drawing, in the Trustees' Academy of Edinburgh. In 1840 he produced one of his finest pieces, Prince Charles Edward and the Highlanders entering Edin-

¹ Of these the only copy known to exist is preserved in the Advocates' Library, Edinburgh. This unique volume was reprinted in 1827 under the title *The Knightly Tale of Golagrus and Gawan, and other ancient poems printed at Edinburgh by W. Chepman and Andrew Myllar in the year 1508*, 4to.

burgh after the Battle of Prestonpans. This painting secured his election as an associate of the Royal Academy in 1843. In that same year he produced his no less famous picture of Charles Edward asleep after Culloden, protected by Flora Macdonald, which, like many other of his pieces, has been often engraved. In 1844 appeared his *Cupid and his Martyrdom* of John Brown of Priesthill, the last effort of his pencil, with the exception of a portrait of himself, now in the National Gallery in Edinburgh. He particularly excelled in his portraits of ladies and children. He died at Edinburgh, May 25, 1845.

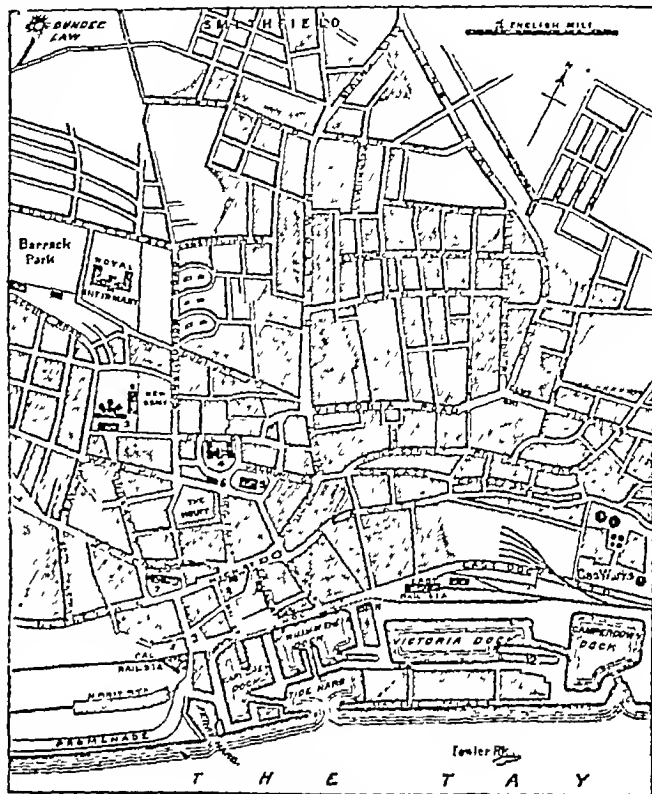

DUNDALK, a parliamentary borough, seaport, and market-town of Ireland, county Louth, on the south bank of the Castletown river, near its mouth in Dundalk Bay, 50 miles north of Dublin. It consists of one long street intersected by several shorter ones. The parish church is an old and spacious edifice with a curious wooden steeple covered with copper, and the Roman Catholic chapel is a handsome building in the style of King's College Chapel, Cambridge. The other public buildings that may be noted are the Exchange Buildings (containing the town hall and a free library), the county court house and prison, the union workhouse and infirmary, and the cavalry barracks. There are several educational establishments in the town. The municipal government is in the hands of town commissioners, and the port is under the control of harbour commissioners. The county assizes are held in the town, as well as quater and petty sessions; and it returns one member to Parliament. A brisk trade, chiefly in agricultural and dairy produce, is carried on, and the town contains some manufactories. Distilling and brewing are the principal industrial works, and there are besides a flax and jute spinning mill, salt works, &c. The port and harbour of Dundalk have recently been undergoing extensive improvements. The course of the river has been straightened, and the bar and harbour deepened, so that vessels of considerable draught can now come up to the town. In the reign of Edward II Dundalk was a royal city, and Edward Bruce proclaimed himself king there in 1315. Population in 1851, 9995, and in 1871, 11,377. Area, 1386 acres.

DUNDAS, HENRY. See MELVILLE, VISCOUNT.

DUNDEE, a royal and parliamentary burgh and seaport, is situated on the east coast of Scotland, in the county of Forfar, on the north bank of the Firth of Tay, twelve miles from the confluence of that estuary with the German Ocean. It is the third town in Scotland as regards population, and the second in commercial importance. Its latitude is $56^{\circ} 27' N$, its longitude $2^{\circ} 58' W$; it is distant from Edinburgh 42 miles N.N.E., from Perth 22 miles E., and from Forfar, the county-town, 14 miles S. It extends nearly three miles along the shores of the Tay, and varies in breadth from half a mile to a mile, and the ground gradually rises towards the hill of Balgay and Dundee Law, the summit of the latter being 535 feet above the sea-level. Its general appearance is pleasing and picturesque, and the surrounding scenery very beautiful.

Dundee is the chief seat of the linen manufacture in Britain, and from a very early time appears to have had a special reputation in this branch of industry. Hector Boece, a native of the town, in his *History and Croniklis of Scotland*, thus quaintly refers to it: "Dunde, the town quhair we wer born; quhair mony virtewus and lauborius pepill ar in, making of clath." It was not, however, till the introduction of steam power, in the beginning of the present century, that there was any remarkable development of flax-spinning in Dundee. The first work of importance was the Bell Mill (which is still extant), built in 1806, and the first power-loom factory was erected in 1836. Side by side with the extension of the linen trade

has been that of jute spinning and weaving. Large cargoes of this material are imported into Dundee direct from India, and it is manipulated on an enormous scale. In fact, the manufacture of flax, hemp, and jute fabrics constitutes the staple trade of the town, and supports, directly or indirectly, the great bulk of the inhabitants. There are upwards of seventy steam spinning-mills and

power-loom factories, employing above 50,000 persons. Some of these buildings are of great size and considerable architectural elegance, those of Messrs Baxter, Messrs Cox, and Messrs Gilroy being especially conspicuous. These three afford employment to above 12,000 hands. The principal textile productions are osnaburgs, dowlas, canvas, sheetings, bagging, jute carpeting, &c., and the total value of these fabrics annually produced has been estimated at upwards of £7,000,000. Among the other industries of Dundee may be mentioned ship-building, engineering, tanning, and leather manufactures (including shoemaking by machinery), all of which are conducted on a large scale. There are also considerable foundries, breweries, corn and flour mills, and confectionery and fruit-preserving works—Messrs Keiller & Son's "Dundee marmalade" having a most extensive reputation. The prosperity of Dundee is in a large measure due to its commodious harbour and its magnificent docks. The harbour works extend about two miles along the river side, and the docks, five in number, cover an area of 35 acres. Although they cannot compare in extent with those of London or Liverpool, they are probably unsurpassed in the kingdom for stability and convenience. They have cost, from 1815, when the works were begun, to May 1877, £800,000; and the harbour revenue amounted in 1876 to £50,751. The principal imports for year ending May 1876 were

Flax, codilla, and hemp	31,300 tons.
Jute	106,727 "
Coals	146,399 "
Timber	46,256 loads
Whale and seal blubber	1,694 tons
Breadstuffs ...	6,508 "

The principal exports were

Linen and jute manufactures—first six months	346,472 pieces.
second	19,117 tons
Bags and sacks	first 12,001,032
second	8,853 tons
Yarns	8,630
Grain	3,506 "

There were built at Dundee, in 1876, 32 vessels with a tonnage of 18,794, and at the end of that year the shipping belonging to the port consisted of

156 sailing vessels	..	tonnage 68,314
38 steamers	..	17,078

Total 194 tonnage 85,392

Eleven of the steamers are in the seal and whale fishing trade, each making two voyages yearly to the Arctic Seas.

The principal public buildings are the following.—The Town-House, designed by "the elder Adam," and erected in 1731, a plain but pleasing structure, the Custom-House, the Post-Office, the Town Churches, an imposing group, surmounted by a noble old tower, St Paul's Free Church, with spire 167 feet high, St Paul's Episcopalian Church, designed by Sir G. G. Scott, with spire 211 feet high; the High School, a fine specimen of Grecian Doric, designed by Angus; Morgan Hospital, erected and endowed by bequest (amounting to nearly £80,000) of the late Mr John Morgan, a native of Dundee, for the board and education of a hundred boys; the Royal Infirmary, a magnificent structure in the Tudor style, designed by Coe and Godwin, and costing about £15,000, the Lunatic Asylum; the New Orphan Institution; the Industrial Schools; the Convalescent Hospital, the Asylum for Imbecile Children; the Deaf and Dumb Institution, the Royal Exchange; the Clydesdale Bank, the court-house and police buildings, with a fine bold portico; the Eastern Club, designed by Pilkington and Bell; the Christian Young Men's Association Buildings, the Theatre Royal, drill hall, newspaper offices, and public baths. To these may be added as deserving of notice the Royal Arch, designed by Mr Rothead, and commemorating Her Majesty's visit to Dundee in 1844, and the Albert Institute, a Gothic building in memory of the late Prince Consort (mainly designed by Sir G. Gilbert Scott), and erected, at a cost of upwards of £20,000, on a site purchased for £8000. Bronze statues of George Kinloch, the first M.P. for Dundee in the Reformed Parliament, and James Carmichael, the engineer, have been erected in Albert Square.

The most notable of the few antiquities of Dundee is the "Old Steeple" (dating from the 14th century), 156 feet high, which has been recently restored, under the direction of Sir G. Gilbert Scott, R.A., at a cost of £7000. Dudhope Castle, the old seat of the Scrymgeours, hereditary constables of the burgh, and granted by James II. to Viscount Dundee, is now used as barracks. The old custom-house, in the Green Market, is a quaint building of the 16th century. The East Port, the sole relic of the ancient walls, is allowed to stand in commemoration of George Wishart the martyr, who, according to tradition, preached from it during the plague in 1544. The pillar of the old town cross, bearing date 1586, has been re-erected. In High Street, Vault, Castle Court, and Fish Street there still remain a few buildings of the 16th and 17th centuries. But the castle, the mint, and the numerous convents have entirely disappeared, the last of the monastic buildings, once occupied

by the nuns of St Clare, having been demolished only a few years ago. The old burying-ground (or "Howff"), now closed, contains many interesting monuments and epitaphs. Three spacious suburban burying-grounds have taken its place—the Western Cemetery, the Eastern Necropolis, and the Balgay Cemetery. Till the middle of the present century, or even later, many of the streets were narrow and irregular, and many of the buildings unhealthy and unsightly; but of late a great change for the better has taken place. Under the Improvement Act of 1871, the narrow gorge

Arms of Dundee

of the Murraygate has been swept away, the ugly and tortuous Bucklemaker Wynd has been transformed into the spacious Victoria Road, with the Victoria Bridge at its upper end, and a dense and dingy mass of buildings between Meadowside and Seagate has been replaced by Commercial Street, which, when completed, will be one of the finest civic thoroughfares in Britain. Many improvements still remain to be accomplished, and although the total cost will probably amount to £400,000, it is expected that there will be ultimately a profit on the street improvements. By the aid of local building societies a large number of working men's houses have recently been erected; and a double line of tramways has been laid from the post-office to the west end of the town.

Dundee is well supplied with recreation grounds. The Baxter Park, 35 acres in extent, designed by Sir Joseph Paxton, was presented by Sir David Baxter to the community in 1863, the pavilion contains a marble statue of the donor by Sir John Steell, erected by public subscription. The Balgay Park, a picturesque wooded hill commanding fine prospects on every side, was secured by the police commissioners and opened to the public in 1871. Besides these there are the Magdalen Green, the Barrack Park, the Bleaching Green, and Dundee Law. A magnificent promenade along the river side between Magdalen Point and the Craig Pier has lately been opened. It is called the Esplanade, and incloses a space of 54 acres, which when filled up will give ample station and traffic accommodation for the Caledonian and North British railways, and leave the public a clear carriage-way and foot-path by the river side. The expense of the undertaking (about £40,000) is borne in nearly equal proportions by the two railway companies and the Harbour Trustees. An extensive abattoir and cattle market have recently been constructed by the police commissioners at the east end of the town. Dundee has regular and frequent steam-boat traffic with London, Hull, Newcastle, Liverpool, Leith, and Rotterdam. To render communication with the south more direct, the North British Railway Company designed the Tay Bridge, a colossal work, completed in 1877 (see BRIDGES, vol. iv p 340).

The water supply of Dundee is copious and excellent. Thirty years ago works were established at Monikie, but in time the quantity (about 2½ million gallons per day) proved insufficient, while the quality deteriorated. The loch of Lintrathen, 20 miles distant, with necessary grounds, was accordingly purchased for £33,108. The surface of the loch, originally 180 acres, has been raised 20 feet, and is now 405 acres in extent, the storage capacity is 257,000,000 cubic feet, the drainage area, 19,000 acres. The main pipe from Lintrathen, 27 inches in diameter, transmitting 8 million gallons per day, conveys the water to Clatto reservoir, four miles from the town, which has an area of 21 acres, and holds 80 million gallons; two pipes from Clatto lead to the service reservoirs. The total cost of the works exceeds £305,000.

Dundee possesses a large number of benevolent institutions, as well as "mortifications" (dating from 1656 downwards) for charitable or educational purposes.

Among eminent men who were natives of Dundee may be named Hector Boece or Boethius, historian, born about 1465; John and Robert Wedderburn, authors or collectors of the book of *Gude and Godlie Ballatis* published 1578; Sir George Mackenzie, the celebrated lawyer, born in 1636; Rev. John Willison, author of *The Afflicted Man's Companion*, born 1680; Viscount Duncan of Camperdown, born 1731; James Ivory, an eminent mathematician, born 1765; and Dr Dick, author of *The Christian Philosopher*, born 1774. The father of Thomas Hood, author of *The Song of the Shirt*, was a native of the town, and Hood's first literary production appeared in the *Dundee Advertiser*, about 1816. Robert Nicoll, "Scotland's second Burns," at one time kept a circulating library in Castle Street, and William Thom, the Inverury poet, rests in the Western Cemetery, where a monument was erected by public subscription over his grave.

Statistics—The terrible havoc resulting from the siege of 1651 greatly checked the progress of Dundee, but the following century witnessed the beginning of that rapid and healthy growth which of late years has been so marked. The following figures show the population at successive periods of 30 years since 1755:—

1755	Population 12,480	1841... ..	Population 64,629
1781	" 15,706	1871	" 121,975
1811	" 29,716	1877(estimated) 142,251

In 1876 the births numbered 5231, deaths 3076, marriages 1222. The birth-rate was 37 and the death-rate 22 per 1000.

The rainfall in Dundee for 1876 was 43.12 inches, which is considerably above the average, in fact, the highest of any recorded year except 1872, when it was 43.70. The number of "wet days" in 1876 was 280, being 50 above the average. The prevailing winds are westerly.

Previous to 1832, Dundee was grouped with Forfar, Perth, Cupar, and St Andrews in returning a member to Parliament; the Reform Act gave it the privilege of a member for itself, and the Act of 1868 added another. For municipal purposes the town is divided into nine wards, the third of which includes the populous and thriving suburb of Lochee. The town council is composed of the provost, dean of guild, 6 bailies, and 20 councillors, these are also the police and water commissioners. Part of the town being in the parish of Dundee, and part in the united parishes of Liff and Benzie, there are two parochial boards. When the Education Act came into operation (1873) there was class-room accommodation within the burgh for 17,719 pupils, and since then the school board has built or enlarged 10 schools. In 1877 there was accommodation for 20,615 pupils, and the number of children in the town of school age, that is from 5 to 13 years, was estimated at 21,000. The principal educational institution is the high school, where an excellent curriculum is available, and since 1875 classes, taught by professors from St Andrews, have been opened for the study of chemistry, geology, physiology, and literature.

In 1866 the ratepayers cordially adopted the Free Libraries' Act, and advantage has been largely taken of the privileges thus afforded. The library premises are centrally situated in Albert Square, and include a lending library, reference library, museum, and picture gallery, admission being free. In the lending library there are 25,000 volumes, in the reference library 5500. A fine arts exhibition is occasionally held within the free library buildings, and an Art Union for Dundee has just been sanctioned by the Board of Trade.

There are 78 places of worship in the town, which may be classified as follows:—In connection with the Established Church, 16; Free Church, 20; U.P. Church, 11; Congregationalist, 6; Episcopalian, 5; Roman Catholic, 4; Baptist, 3; other denominations, 13.

Lochee, a suburb of Dundee, forming part of the municipality, is situated about two miles to the north by the Coupar-Angus road. Till within recent years only a small country village, it has now a population of 15,000. It contains several flax and jute factories,—by far the largest and most comprehensive in the whole district being the Camperdown Linen Works, belonging to Messrs Cox Brothers and Co. They cover an area of 25 acres, and employ upwards of 5000 persons. The most striking external feature, and one of the prominent landmarks in the district, is the stately chimney-stalk (282 feet high) in the style of the Italian campanile, built of parti-coloured bricks, with stone cornices.

Broughty Ferry, three miles distant, towards the mouth of the Firth of Tay, may also be considered as a suburb of Dundee. The name originally *Brach-tay*, is believed to be Pictish, and refers to the castle or fortress, which is mentioned repeatedly during the

Wars of the 16th century. Its picturesque ruins continued till about 1857, when they were removed to make way for the present fort, which is intended as a defence for the Tay, and which mounts 9 guns, and can accommodate 60 men. Broughty Ferry is a burgh under the General Police Act, which was adopted in 1864, and is partly in the parish of Dundee partly in that of Monifieth. Some thirty years ago it was only a fishing village, although designed and partly laid out with a degree of breadth and regularity in the streets which fishing-villages rarely display. The population in 1861 was 3513, in 1871 it was 5707, and now (1877) it is estimated at 8000. There are nine churches of various denominations, the finest, in an architectural point of view, being the East Free and the Episcopalian, the latter designed by Sir G. G. Scott. Some of the villas on and around Fort Hill, occupied by Dundee merchants, are exceedingly handsome. Reres Hill and the Castle Green have been acquired by the commissioners of police as recreation grounds for the use of the public.

History—Dundee is said to have been at one time called *Alectam*, but of this assertion there is no explicit documentary evidence. The earliest authentic mention of the town is in a deed of gift by David earl of Huntingdon, dated about 1200, which distinctly designated it "Dunde." The origin of the name is disputed,—some absurdly tracing it to the Latin *Donum Dei*, "the gift of God," others to the Celtic *Dun Dhu*, the Hill of God, others to *Dun-tay*, the hill or fort on the Tay; the last named derivation is the most probable. Dundee was erected into a royal burgh by William the Lion, and has always been a place of considerable importance, figuring conspicuously in the early history of Scotland, especially about the time when Bruce and Baliol were contending for the crown. It was here that Wallace was educated; and here he struck the first blow against the English domination. In the great Reformation movement of the 16th century the inhabitants took such a leading and active part as to earn for the town the appellation of "the Scottish Geneva." Few places have been subjected to more frequent or serious calamities. It was twice taken by the English in the reign of Edward I., again in that of Richard II., and a fourth time in that of Edward VI. The marquis of Montrose took it by assault, and set part of it on fire in 1645, and in 1651 it was besieged by General Monk, and, after an obstinate resistance, was taken by storm, and given up to plunder and massacre. It was then probably the most opulent, and was certainly the best fortified town in Scotland, and many people of note from Edinburgh and elsewhere had found refuge within its walls. More than one-sixth of the inhabitants and garrison, including the brave governor Lunisden, were put to the sword; while the plunder was so great as to fill 60 vessels which were seized in the harbour; but, says Gumble in his life of Monk, "the ships were cast away within sight of the town, and that great wealth perished." Notwithstanding the number of burnings and plunderings to which Dundee has been subjected, the collection of charters, council-records, and other ancient documents preserved in the archives of the Town House is remarkably interesting and complete. There are characteristic dispatches from Edward I. and Edward II., the original charter of King Robert Bruce, dated 1327, a papal order from Leo X., and a letter from Queen Mary, dated 1564, providing for extra-mural internments. (C. C. M.)

DUNDEE, JOHN GRAHAM OF CLAYHOUSE, VISCOUNT (1643–1689), born in or about the year 1643, was the elder son of Sir William Graham and Lady Jean Carnegie. Of his youth little record has been kept; but in the year 1665 he appeared in St Andrews as a student of St Leonard's College. His education was upon the whole good, as appears from the varied and valuable correspondence of his later years. Young Graham was destined for a military career; and, having remained in St Andrews for about four years, he proceeded abroad as a volunteer in the service of France. Thereafter, in 1672, he went to Holland, and obtained the post of cornet in one of the cavalry regiments of William, prince of Orange. In 1674 he was raised to the rank of captain, as a reward for having rescued the prince from a marsh where his horse had foundered during a retreat. Shortly afterwards, William having at his disposal the command of one of the Scotch regiments in Holland, Graham made application for the post. He was not appointed, and resigned his commission. In the beginning of 1677 he returned to England, bearing, it is said, letters of strong recommendation from William to Charles II. and the duke of York.

Early in 1678 he accepted a lieutenancy in a troop of horse under the command of his relative the marquis of Montrose. Promotion immediately followed. He was ex-

pressly nominated by Charles II. to the command of one of the newly raised troops of cavalry. From the time, indeed, of his return to Scotland he assumed an influential position. His prestige as a soldier, his uncompromising disposition, and his unmistakable capacity, at once marked him out as a leader upon whom Government could rely. In the end of the year he was despatched with his troop to Galloway to suppress the disorders which prevailed in the district. He had a difficult and unpopular task,—that of carrying out the policy of Lauderdale in the most disaffected part of Scotland. The Act of 1670, imposing the punishment of death and confiscation of goods, was still in operation, and the Covenanters had for years before Graham's return to Scotland propounded the theory that opposition to the Government and the actual slaughter of the king were not only just, but a religious duty. Opposition to Lauderdale's measures, however, was winked at by the duke of Hamilton, and the recent authorized inroad of the Highlanders had widened the area of dissatisfaction. It is not wonderful that the success of Graham in his mission was small. He entered, however, upon his occupation with zest, and interpreted consistently the orders he received. There is evidence, also, that his efforts were appreciated at headquarters, in his appointment, jointly with the laird of Earls-hall, to the office of sheriff-depute of Dumfriesshire in March 1679, with powers—specially narrated in his commission—anent "separation," conventicles, "disorderly baptisms and marriages," and the like.

For some years thereafter the position of Graham was perhaps as difficult and delicate as one man was ever called upon to occupy. In the midst of enemies, and in virtue of the most erroneous but direct orders of his Government, he combined the functions of soldier, spy, prosecutor, and judge. Shortly after the murder of Archbishop Sharp, on 5th May 1679, he was summoned to increased activity. There were reports of an intended gathering in the neighbourhood of Glasgow, and at the head of his dragoons Graham went in pursuit of the rebels. On Sunday the 1st of June, the Covenanters having removed from Loudon Hill to a well-protected position upon the marshy ground of the farm of Drumclog, Graham, who had gone in search of them, advanced. Hindered from the attack by the nature of the ground, he had to wait till the impatience of his adversaries, who were under better leadership than they ever afterwards enjoyed, induced them to commence an impetuous attack. Headed by the youthful Clelland, the Covenanters charged the cavalry, who in a little turned and fled. The loss of the victors was but three men, while thirty-six dragoons were killed, Graham himself having a narrow escape. This was the only regular engagement he had with the Covenanters. Small as it was, the result raised an enthusiasm in the bosoms of the victors, and was the beginning of an actual rebellion.

On the 22d June Graham was present at the battle of Bothwell Bridge, at the head of his own troop. Immediately thereafter he was commissioned to search the south-western shires for those who had taken part in the insurrection. In this duty he seems to have been engaged till the early part of 1680, when he disappears for a time from the record of these stringent measures. His powers during these months were of the most sweeping description; and it appears that his ample commission was most slenderly used. The gravest accusation against him in reference to this period is that he was a robber.

Graham had for some time been recognized as an adherent of the party who were adverse to measures of leniency and conciliation. During these months he was accordingly despatched to London along with Lord Lanthgow to influence the mind of Charles II. against the

indulgent method adopted by Monmouth with the extreme Covenanting party. It is perhaps not to his credit that he succeeded in the object of his mission. He was then in the prime of life, was commandingly handsome in appearance, a lover of sport, and a devoted royalist. Charles seems to have been fascinated by his loyal supporter, and from that moment Graham was destined to rise in rank and honours. On the 21st of April 1680 he obtained a royal grant of the barony of the outlawed Macdowall of Freugh, and the grant was confirmed by subsequent orders upon the Exchequer in Scotland. In April 1680 it appears that his roving commission had been withdrawn by the Privy Council. He is thus free from all concern with the severe measures which followed the Sanquhar Declaration of 22d June 1680.

The turbulence occasioned by the passing of the Test Act of 1681 required to be quelled by a strong hand, and in the beginning of the following year Graham was again commissioned to act in the disaffected districts. In the end of January he was appointed to the sheriffships of Wigtown, Dumfries, Kirkcudbright, and Annandale. He was besides acting captain of a troop of dragoons—the pernicious combination of his offices being thus repeated. He appears further to have had powers of life and death in virtue of a commission of justiciary granted to him about the same time. In his despatches there are indications that he disapproved of a system of indiscriminate punishment, and desired that severe vengeance should only be executed upon ring-leaders and men of rank. This, however, applied solely to the harshest measures then known to the law, those of torture and death. Where these were involved he preferred, after hunting out and seizing his prisoners, to send them to Edinburgh for trial. But within these limits his methods of procedure in the large districts over which he had control were uncompromising, and, if we suppose him to have had sympathy with his orders, most cruel. He quartered on the rebels, rifled their houses, and, to use his own words, "endeavoured to destroy them by eating up their provisions." The effect of his policy, if we believe his own writ, is not overstated as

"Death, desolation, ruin, and decay."

The result of a bitter quarrel with Sir John Dalrymple confirmed the prestige of Graham, who was not only acquitted by the verdict of the Privy Council of the grave charges of exaction and oppression preferred against him, but had the satisfaction of seeing Sir John condemned to fine and imprisonment for interference with his proceedings. On 25th December 1682 he was appointed colonel of a new regiment raised in Scotland, and captain of its leading troop. He had still greater honours in view, and in March 1683 he started for Newmarket to demand an audience of the king. In the preceding January the case of the earl of Lauderdale, late Maitland of Hatton, which involved the question of his malversations with regard to the Scottish mint, was debated in the House of Lords. Maitland was proprietor of the lands and lordship of Dundee and Dudhope, and the decree of the lords against him was in March 1683 issued for the sum of £72,000. Graham succeeded in having the property of the defaulter transferred to him by royal grant, and in May the additional honour was conferred upon him of nomination to the Privy Council of Scotland.

Shortly afterwards Claverhouse was appointed to be present at the sittings of the recently instituted Circuit Court of Justiciary in Stirling, Glasgow, Dumfries, and Jedburgh. The notable objects of the circuit were the imposition of the test and the punishment of rebels. Several were sentenced to death. During the rest of the year he attended the meetings of council. As a statesman he was

incapable of rising to an independent view of affairs, and was unable to overcome his dutiful obedience to superior orders. Although he had had experience of the most disaffected portions of the country, there is but one record of his having interfered to prevent the accustomed irritating measures. He declared decisively against the proposal to let loose the Highland marauders upon the south of Scotland.

In June 1684 he was again at his old employment—the inspection of the southern shires, and in August, after the ambushade of Enterkine-hill, he was commissioned as second in command of the forces in Ayr and Clydesdale to search out the rebels and report to head-quarters. By this time he was in possession of Dudhope, having on the 10th of June married Lady Jean, daughter of Lord Cochrane. As constable of Dundee it is recorded to his honour that he recommended to the Privy Council the remission of extreme punishment in the case of many petty offences. He issued from his retirement to take part in a commission of lieutenancy which perambulated as a criminal court the southern districts, and in the end of the year he was again in the same region on the occasion of the disturbances in the town of Kirkeudbright.

Shortly after the death of Charles II. (6th February 1685), Graham, through the jealous efforts of Queensberry, incurred a temporary disgrace by his deposition from the office of privy councillor, but in May he was reinstalled, although it is to be observed that his commission of justiciary which had expired was not renewed.

In May 1685 he was ordered with his cavalry to guard the borders, and to scour the south-west in search of rebels. By Act of Privy Council, a certificate was required by all persons over sixteen years of age to free them from the hazard of attack from Government officials. Without that they were at once liable to be called upon oath to abjure the declaration of Renwick, which was alleged to be treasonable. While on this mission he pursued and overtook two men—John Brown, and a nephew whom he calls John Brownen. Brown, having refused the abjuration oath, was shot dead. The order was within the authorized power of Graham.

Until 1688 there is little more of note in his career. In 1686 he was promoted to the rank of major-general, and had added to his position of constable the not inconsiderable dignity of provost of Dundee. He appears, however, in the Privy Council in 1688 opposing the proposal that Lieutenant-General Douglas should have command of the whole army which had been ordered to England to aid the falling dynasty.

A week or two after his departure with the army his fascinating influence had made itself felt upon James II., and amid the hurry of events he was created viscount of Dundee on 12th November 1688. From York he went to Salisbury, where he advised James to sterner measures than the feeble-hearted monarch had the courage to adopt. Throughout the vexed journeyings of the king, Dundee is found accompanying or following him, endeavouring in vain to prompt him to make his stand in England and fight rather than flee from the invader. At last James announced his resolve, with the promise that he would send from France an appointment in favour of Dundee to command the troops in Scotland, and arrangements were entered into for communication with the voluntary exile.

Dundee returned to Scotland in anticipation of the meeting of the Convention, and at once exerted himself to increase the waning resolution of the duke of Gordon with regard to holding Edinburgh Castle for the exiled king. He had conceived the idea of forming a rival Convention at Stirling to sit in the name of James II., but the hesitancy of his associates rendered the design futile, and it was given up. Dundee, however, boldly appeared at the first meeting of

Convention on 16th March 1688, and disclosed a plot which he declared he had discovered against his own life, but the matter after some inquiry was departed from.

On the 18th of March, despising the fears of his promised allies, he left Edinburgh at the head of a company of fifty dragoons, who were strongly attached to his person. He was not long gone ere the news was brought to the alarmed Convention that he had been seen clambering up the west side of the castle rock and holding conference with the duke of Gordon. In excitement and confusion order after order was despatched in reference to the fugitive, and the Convention sat with locked doors to prevent communication with traitors without. Dundee retired to Dudhope. On the 30th of March he was publicly denounced as a traitor, and in the latter half of April attempts were made to secure him at Dudhope, and the residence in Glen Ogilvy to which he had retired. But the secrecy and speed of his movements outwitted his pursuers, and he retreated to the north. His career presents strange peculiarities. It was only in 1678 that he had returned to Scotland from abroad. Yet in the short period of intervening years he had, despite the opposition of his superiors in rank, risen from the post of captain, and the social status of a small Scotch laird, to positions as a soldier and statesman and the favourite of his sovereigns, of the greatest dignity, influence, and wealth. Yet it was in this period that he committed those acts on account of which his memory is loaded with reproach. When the ruling dynasty changed, and he who had so often been commissioned to quell insurrection had himself become an outlaw and a rebel, he supported the cause of his exiled monarch with such skill and valour that his name and death are recorded as heroic.

On his march into the Highlands he commenced among the chieftains the diplomatic policy in which he excelled. General Hugh Mackay was now in the field against him, and what was simply a Highland chase began. Mackay started with a body of cavalry, marched to the north, and having refused reinforcements from the untrained peasantry of Aberdeenshire, pushed the pursuit further and further to the west. Elgin, and latterly Inverness, were occupied by the Government troops. Dundee had in the meantime been scouring the country from Perth, which on the 11th of May he had plundered, to the wilds of Lochaber, to which he had latterly retired. The clans were assembled by the 28th of May, and on the 29th the castle of Ruthven, near Kingussie, was seized. The army of Dundee was now much superior in numbers to that of Mackay, and the prudent general beat a hasty retreat. Having received reinforcements, however, he again advanced northward, and in Strathdon, in the early part of June, it seemed likely that the opposing forces would meet. But the Highland warriors, laden with plunder, were returning homeward, and the army of Dundee was melting away. The outlawed leader again retired, and Mackay conceived his mission at an end. He proceeded westward, and, having garrisoned Inverness, marched to the south.

Throughout the whole of the campaign Dundee was indefatigable in his exertions with the Highland chiefs and his communications with his exiled king. To the day of his death he believed that formidable succour for his cause was about to arrive from Ireland and France. He justly considered himself at the head of the Stewart interest in Scotland, and his despatches form a record of the little incidents of the campaign, strangely combined with a revelation of the designs of the statesman. It mattered little to him that on the 24th of July a price of £20,000 had been placed upon his head. The clans had begun to reassemble, and he was now in command of a considerable force.

Mackay, who had visited Edinburgh to report events, re-

turned to Perth, whence, with an army now amounting to about 4000 men, he proceeded to Dunkeld on the 26th of July. While in the metropolis he had endeavoured to secure the Athole interest, and that the castle of Blair should be held for King William. But he was as usual outwitted by Dundee, who, after unsuccessful negotiations with Lord Murray, won over the Athole factor by the presentation of a commission prepared for the occasion. The castle was at once occupied, and at Dunkeld Mackay received intelligence that the design of his march was frustrated. By ten A.M. of the 27th of July 1689 he was at the entrance to the pass of Killiecrankie.

Dundee had appointed a gathering of the clans at Blair for the 29th, and on the 27th he was at the head of at least 2000 men, including a contingent from Ireland. The reports of scouts that 400 of the enemy had already threaded the pass roused the impatience of the chiefs. But it was not until he received intelligence that the whole army of Mackay had entered the defile that he gave the order to march. With caution he disposed his troops on the hills to the right of the opposing army, which, making its exit from the gully, was forming on the haughs. On Mackay's right and beyond the narrow plain were undulating heights backed by Craig Culloch. On one of these Mackay was astonished to observe the movement of the troops of Dundee. To prevent the enemy from gaining an intervening eminence, he at once ordered a flank movement, and his army marched up the face of the hillock, leaving the Garry in the rear. For several hours the two armies faced each other, Dundee restraining the impatience of his troops, but at eight in the evening the order was given to advance. Mackay had formed his line three deep, while his opponent had arranged his men in battalions with intervals wide enough to prevent the outflanking of superior numbers. The Highlanders having discharged their firelocks threw them on the ground, and rushed impetuously on the foe. The result was instantaneous; Mackay's line was broken and driven helplessly into the gorge. Dundee, at the head of his cavalry, charged the enemy, but, confusion having arisen as to the leadership of the troop, he was not at once followed. The gallant soldier, waving on his men, was pierced beneath the breastplate by a bullet of the enemy, and fell dying from his horse. Dundee asked "how the day went," and, hearing the answer and the expression of sympathy, replied that "it was the less matter for him seeing the day went well for his master." He was conveyed to the castle of Blair, where within an hour or two of his death he was able to write a short account of the engagement to King James. The battle, in which the Government forces had lost 2000 men as against 900 of the enemy, was in truth the end of the insurrection. The Highland camp was broken by jealousies, for the controlling and commanding genius of the rebellion was no more.

See *Memorials and Letters of Graham of Claverhouse*, by Mark Napier, 1859-62, where the literature of the subject is referred to. The work itself must be read with caution. (T. S.)

DUNDONALD, THOMAS COCHRANE, TENTH EARL OF (1775-1860), known during his brilliant naval career as Lord Cochrane, was born at Annsfield, in Lanarkshire, on the 14th December 1775. His father, the ninth earl, had great scientific attainments, especially in chemistry, and possessed a genius for invention which ruined his fortune without much benefiting any one. He was so poor that the education of Thomas, his eldest son and heir, was left very much to such volunteer instructors as the parish minister. At the age of seventeen Lord Cochrane joined the navy on board the "Hind," of which his uncle, afterwards Admiral Sir Alexander Cochrane, was at the time captain. His father had previously procured for him a commission in the 79th regiment, but his own preference

for the other branch of the service was so decided that it was found necessary to gratify it. In 1795 he was transferred with his uncle to the frigate "Thetis," which proceeded to the North American station. Soon afterwards he received his lieutenant's commission, and in 1798 he was sent to the Mediterranean to serve in the fleet under the command of Lord Keith. He had already begun to show that rare combination of daring and prudence which probably no British naval officer, save Nelson, ever possessed to a greater degree. As commander of the sloop "Speedy," to which he was appointed in 1800, he performed a series of exploits in capturing vessels of immensely larger size than his own which are almost without parallel in the annals of naval warfare. The little "Speedy," with its miserably weak armament of four-pounders, became the terror of the Spanish coasts, and more than once she was honoured by a frigate being especially detached to capture her. One of the attacks she ingeniously evaded; another she boldly met (28th February 1801), and actually succeeded in capturing her opponent, the "El Gamo," a Spanish frigate of 32 guns. Her cruise of thirteen months, during which she took upwards of fifty vessels with 122 guns and 534 prisoners, ended in her own capture by three French line of battle ships, after making so gallant a resistance that the French captain, to whom Cochrane delivered up his sword, at once returned it. After a brief imprisonment, Lord Cochrane was exchanged. The promotion to post-rank, to which he was fully entitled, came somewhat tardily in August 1801, and the persistence with which his claims had to be urged laid the foundation of the bad understanding with the authorities at the Admiralty that caused him to be lost to the British service a few years later, while he was still in his prime. Its immediate result being that he was refused further employment, he spent the period of enforced leisure (1802) at the university of Edinburgh, where he wisely endeavoured to repair the defects of his early education. The renewal of hostilities in 1803 brought him the opportunity of such distinction as was likely to be gained in the command of the "Arab," an utterly unseaworthy old collier purchased into the navy, in which he was sent to take part in the blockade of Boulogne. The animus against him in official circles was clearly shown when, on his complaining that his vessel was unfit for service, he was sent to the North Sea to protect non-existent fisheries. In 1804, on the advent of Lord Melville to the head of the Admiralty, tardy justice was done by his appointment to the command of the new frigate "Pallas" (32), in which, after making several valuable prizes within ten days, he entered Plymouth harbour in charge of them with three golden candlesticks, each five feet high, at the mastheads as a sample of the spoils. Before the "Pallas" was again sent to sea her fortunate captain was returned to Parliament as member for Hoxton, partly through the influence of his fame, but still more through the influence of his prize-money. In her second cruise the "Pallas," after conveying a merchant fleet to Quebec, returned to the coast of France, where she cut out and captured several of the enemy's corvettes, and destroyed many of the signals. In August 1806 Lord Cochrane was transferred to the command of the "Imperieuse" (44), in which during the succeeding two years he did immense damage to the enemy's fleet in the Bay of Biscay and the Mediterranean. One of his most gallant exploits during this period was his defence of Fort Trinidad, near Rosas, which he held for twelve days (November 1808) against overwhelming odds. When he found further resistance impossible he blew up the magazines and returned to his ship.

Meanwhile, though his services were so distinguished, his relations with the Admiralty had not become more friendly. At the general election in May 1807 he had been returned

triumphantly for Westminster in the Radical interest, along with Sir Francis Burdett; and during a brief interval spent at home, while he was in command of the "Imperieuse," he had rendered himself still further obnoxious as a critic in Parliament of naval abuses. In 1809, however, the authorities had occasion for a daring service which he alone was found competent and willing to undertake. It had been suggested to them that the French fleet blockaded in Basque Roads might be destroyed by means of fire ships, and the hazardous duty was intrusted to Cochrane. On the night of the 11th April he personally piloted the vessels loaded with explosives to the entrance of the harbour, where they spread such terror that seven French frigates slipped their cables and ran on shore, five of them being afterwards destroyed. Unfortunately this first success was not followed up as it ought to have been. Lord Gambier, the commander of the blockading fleet, ignoring the repeated and urgent requests of Cochrane, refused to order a general attack, and thus the opportunity of destroying the whole of the enemy's ships was lost. Lord Cochrane was bitterly disappointed, and made no attempt to conceal his opinion of the incompetency of his superior, who found himself compelled to demand a court martial. The trial was worse than a mockery, the court was packed, witnesses were manipulated, and charts fabricated,—with the scandalous result that Gambier was acquitted and Cochrane by implication disgraced. There was, of course, no further professional employment for one who had been stigmatized as a false accuser. For four critical years Lord Cochrane held no command, and his country lost the services of one of the few naval heroes she has had worthy to be named along with Nelson. In his place in Parliament he did what he could to secure a reform of the many abuses connected with the administration of the navy, and his unsparring criticisms greatly embittered his already unfriendly relations with the Admiralty and the Government. In 1814 an unfortunate concurrence of circumstances, suspicious in themselves though capable of a satisfactory explanation, led to his being accused, along with several others, of a conspiracy to defraud the Stock Exchange, by circulating a false report of the success of the Allies and the death of Napoleon. He had only a week or two before so far overcome the disfavour with which he was regarded by the Admiralty as to secure his appointment to the command of the "Tonnant," the flag-ship of his uncle Sir Alexander Cochrane, but he had to resign the position in order to meet the prosecution which the Government were not slow to institute. The trial was conducted before Lord Ellenborough, a noted partisan, who, if he did not, as Cochrane's friends have insinuated, exceed the limits of his office in order to secure a conviction, certainly showed no favour to the accused, who were all found guilty. Lord Cochrane was sentenced to a fine of £1000, twelve months' imprisonment, and an hour in the pillory. His ruin and disgrace were completed by his being expelled from the House of Commons, and deprived with the usual humiliating ceremony of the knighthood of the Bath, which had been bestowed on him after his heroic service at Basque Roads. Popular sympathy, however, was strongly with him. An influential minority of forty-four voted against his expulsion from the House of Commons, and when a new writ was issued for Westminster he was unanimously returned, no one having ventured to stand against him. A public subscription was raised by his constituents for the payment of his fine. His colleague, Sir Francis Burdett, pledged himself to stand along with him in the pillory if that part of the sentence was carried out, and the Government judged it prudent to remit it. Lord Cochrane's conduct was throughout that of an innocent, if somewhat imprudent, man. At his trial he volunteered a full explanation of the

suspicious circumstances that were urged against him, and after his conviction he took every opportunity of protesting against the injustice that had been done him, and was urgent in his demand for a new inquiry. During the currency of his sentence he contrived to make his escape from prison, and took his seat in the House of Commons, from which he was forcibly removed by the warden and officers of the King's Bench.

At the close of his imprisonment Lord Cochrane soon found that there was little hope of his being again actively engaged in the service of his native country. The peace that followed Waterloo promised to be enduring, and, even had it been otherwise, he could not expect employment, as his name had been struck off the navy list. When, therefore, the command of the fleet of the republic of Chili was offered to him in 1818, he at once accepted it, finding a congenial task in the endeavour to aid a weak state in its struggle for freedom. He arrived at Valparaiso in November 1818; and in a short time afterwards he was ready for action, though the fleet under his command was in every respect miserably weak when compared with that of Spain, to which it was opposed. It seemed almost the characteristic feature of his genius, however, that the greater the odds against him the more brilliant the success he achieved, and this was signally exemplified during his career in South America. It is impossible to detail all his marvellous exploits. Two, however, must be specially mentioned as among the most extraordinary achievements in the annals of naval warfare. On the 2d February 1820 he captured Valdivia, a very strongly fortified town and harbour in the possession of the Spaniards, the forces under his command consisting of his own single frigate and 250 land troops in three small vessels. The place yielded to the mere terror of his name, the handful of troops that obtained possession of it being insufficient to man its guns or even to keep its civil population in order. In the autumn of the same year he blockaded the harbour of Callao, one of the strongest in the world. Within it, fixed to chain moorings, protected by twenty-seven gun-boats, and covered by the fire of no less than 300 guns in the batteries, lay the Spanish frigate "Esmeralda." The ambition of Lord Cochrane was fired by the apparent impossibility of the task to attempt his favourite exploit of cutting out. The attempt was made on the night of the 5th November, and, in spite of the apparent impossibility, it was completely successful after a sharp engagement of a quarter of an hour's duration, in the course of which Lord Cochrane was severely wounded. The moral effect of this achievement upon the Spaniards was all that Cochrane had anticipated; they were completely paralyzed, and left their daring opponent undisputed master of the coast. Unfortunately, just at the time when he was rendering her these signal services, the jealousies and intrigues of various members of the Chilian Government were making Lord Cochrane's position uncomfortable, if not untenable. The withholding of prize-money, and even of pay, had nearly caused a mutiny in the fleet, when Lord Cochrane, by taking strong measures to obtain part of what was due to his men, brought on an open rupture between himself and the Government. An invitation from the regent of Brazil to undertake the command of his fleet against the Portuguese was, therefore, accepted as a welcome deliverance. Lord Cochrane entered on his new duties at Rio do Janeiro in March 1822. His services to Brazil were quite as important, though scarcely marked by so many brilliant episodes, as those to Chili, and they were in the end equally ill-requited. His daring capture of Maranhão with a single frigate, in July 1823, added a province to the newly-formed empire, and the value of the accession was acknowledged by the title of marquis of Maranhão being conferred

upon the captor, along with an estate, of which, however, Lord Cochrane never obtained possession. In fact, both by Chili and Brazil he was unjustly defrauded of all substantial rewards, and his connection with the new empire which he had done so much to aid in establishing was ignominiously terminated by his dismissal from her service in 1825. He had given some provocation to this by his obstinacy in refusing to appear at a court-martial, and account for his conduct in taking the frigate under his command to England without orders. The Brazilian Government itself, however, practically admitted the gross injustice with which it had treated him by awarding him twenty years afterwards the pension that had been agreed upon in the first engagement made with him.

On his return to England Lord Cochrane found himself the object of a popularity that had grown rather than abated during his absence. His great achievements had been spoken of in the warmest terms in the House of Commons by Sir James Mackintosh, who urged the Government to restore him to his place in the service of his native land. But the time for the redress of his wrongs was not yet, and, finding inaction impossible, he gladly gave his services to the cause of Greek independence. Appointed by the National Assembly admiral of the Greek fleet, he found himself for the first and only time in his career in a position where success was impossible even for him. The want of union and discipline among the Greek troops frustrated all his plans, and an attempt to relieve the Acropolis at Athens in 1827 ended from this cause in a disastrous failure, Lord Cochrane only escaping by jumping into the sea. In 1828, after the Great Powers had secured the recognition of the independence of Greece, he returned to England.

With the accession of King William and the formation of a Liberal ministry there came at last a tardy and imperfect reparation to Lord Cochrane for the injustice he had suffered. He was restored to his rank in the navy, but with this he had to remain content. It was with bitter and indignant feelings that he found himself compelled to accept a pardon under the Great Seal instead of the new trial he had long and vehemently demanded. And the restoration to his rank was robbed of much of its grace by the facts that the honour of the knighthood of the Bath, of which he had also been deprived, was not restored at the same time, and that the arrears of his pay were withheld. In 1831 he succeeded his father in the earldom of Dundonald. On the 23d November 1841 he became vice-admiral of the blue. Another instalment of the lingering atonement that was due to him was paid in 1847, when the honour of knighthood of the Bath was restored, though, by that strange fatality which seemed to have decreed that no reparation made to him should be complete, his banner was not replaced in the chapel of the order until the day before his burial. In 1848 he was appointed to the command of the North American and West Indian station, which he filled until 1851. Immediately after his return he published *Notes on the Mineralogy, Government, and Condition of the British West India Islands*. When unfitted by advancing age for active service, he busied himself with scientific inventions for the navy, such as improved poop and signal lights, improved projectiles, &c. During the Russian war he revived secret plans which he had detailed to the prince regent nearly fifty years before for the total destruction of an enemy's fleet, and he offered to conduct in person an attack upon Sebastopol and to destroy it in a few hours without loss to the attacking force. That his intellect remained clear and vigorous to the close of his life was shown by the publication in his eighty-fourth year of his *Narrative of Services in the Liberation of Chili, Peru, and Brazil* (1858), and of his *Autobiography*, in two volumes, the second of which appeared just before his death. The literary style

of both works is admirably appropriate to the subject, simple, lucid, and dashing; and the story they tell is one of heroism and adventure that has scarcely its parallel even in romance. The author's burning sense of his wrongs, and his passionate desire for a thorough vindication, reveal themselves at every turn. If he is not unnaturally blind to the fact that his own imprudence and want of self-command contributed in some small degree to his misfortunes, no one will now deny that this "heroic soul branded with felon's doom" suffered more cruel and undeserved wrongs than ever fell to the lot of any warrior of his genius and achievements.

Lord Dundonald died at Kensington on the 30th October 1860, and was buried in Westminster Abbey. (W. B. S.)

DUNEDIN, a city in New Zealand, in 45° 52' 12" S. lat. and 170° 32' 37" E. long., at the head of Otago harbour, an arm of the sea on the east coast of the South Island. It is the capital of the late province and present provincial district of Otago, and was founded as the chief town of the Otago settlement by settlers sent out under the auspices of the Lay Association of the Free Church of Scotland in 1848. The discovery of large quantities of gold in Otago in 1861 and the following years, and the great increase in the production of wool, have made Dunedin a very flourishing place. The city is beautifully situated in an amphitheatre of hills. The streets, nearly all paved and kerbed, have been made at considerable expense and trouble,—some being carried through swamps and others through cuttings and along embankments. The cost of permanent improvements during the last fifteen years has been about £300,000. The town is supplied with pure water, and (since 1862) with gas from works belonging to the corporation. Dunedin is the seat of a judge of the supreme court, and of a resident minister, who is a member of the Colonial Executive; and it also has a Waste Lands Board, a body constituted for the purpose of administering the public estate of the provincial district. The city contains some fine buildings, especially two handsome Presbyterian churches, constructed of white stone from Oamaru. The so-called university of Otago, now affiliated with the university of New Zealand, which alone has the power to grant degrees, possesses chairs of classics, mathematics, mental and moral philosophy, as well as lectureships on botany, mineralogy, law, and modern languages. A museum (well built of concrete) contains an excellent collection of New Zealand flora and fauna, including some fine skeletons of the *Dinornis*. There is also a scientific body called the Otago Institute, affiliated with the New Zealand Institute. There are three good libraries—one at the supreme court, a second at the university, and a larger one at the Athenæum—six banks, and several large mercantile houses. The people are mostly of Scotch origin, with a considerable intermixture of immigrants from England, Ireland, the British colonies, and Germany. All classes are prosperous—except among the extremely limited criminal class, poverty rarely occurs, and absolute pauperism is quite unknown.

Otago harbour, by which the city is approached from the sea, is an inlet about 18 miles long. There is about 22 feet of water on the bar at low tide. Half way up to Dunedin is Port Chalmers, a fine anchorage for the largest vessels, where, owing to the presence of precipitous hills, the land was found too limited in area for a large city. From this point the water grows shallower as it approaches Dunedin. Until lately no vessels drawing more than 10 feet could pass up, but by two years dredging the channel has been made available for steamers drawing 13 or 14 feet, and this depth is gradually being increased. The Harbour Board has authority to raise £250,000 by bonds, of which £129,400 has been raised, but £66,000 is still unexpended. The revenue of the

board is £14,500, which is rapidly increasing, as it arises from a munificent landed endowment. A large part of this money is available for works. The harbour was until lately the terminus of a line of large mail steamers running monthly to San Francisco *via* Auckland and Honolulu, but it is now found more convenient to use smaller steamers for the coastal section. It is, however, still the terminus of a line of fine vessels running at intervals of about ten days to Melbourne, and carrying the monthly mail for Suez and England. There is also direct steam communication with Sydney and Hobart Town, and communication *via* Auckland with Fiji. All the coasting steamers and many sailing vessels are owned in Dunedin. In 1875, besides the San Francisco boats, 69 vessels, varying from 250 to 1800 tons, entered the port from places beyond the seas other than Australasia. The greater number of these arrive in the early part of the summer, and load with wool for London. The customs revenue collected in 1876 amounted to £362,335. The municipal debt amounts to £328,000, and the revenue (raised by rates, rents, water and gas works, &c.) to £47,500. The population of the city in the beginning of 1877 was about 22,500, and that of the suburbs about 9000, while other towns within a circuit of a few miles bring it up to 35,000.

DUNFERMLINE, a city and royal burgh of Scotland, situated in the western district of the county of Fife, about three miles from Limekilns, the nearest point on the Firth of Forth. It is connected with Glasgow by railway *via* Stirling, and with Edinburgh, from which it is distant 16 miles, both *via* Thornton and by a direct line constructed in 1877 to North Queensferry. The town is situated about 300 feet above the sea, on the brow of a slope which ascends from the Forth, and it accordingly commands a very extensive view of the country towards the south. It is intersected from north to south by a deep ravine, at the bottom of which a small stream pursues its tortuous course; and this ravine is crossed by an earthen mound, on which an excellent street is built. At the east end of the town, on the south side of the turnpike road, is a public park comprising about 36 acres, partly the gift of the late Mr Ker of Middlebank, and to the north of the road, at a little distance, are the jail, the workhouse, a hospital, and a cemetery, all in close proximity to each other. The county buildings, with their tall and graceful spire 132 feet high, the new corporation buildings, at present (1877) in course of erection, at an estimated cost of £20,000; the new Assembly Hall, capable of accommodating 1500 persons, now being built by a private company at a probable outlay of £10,000, the Carnegie Public Baths, finished and opened in 1877, and presented to his native town by Mr Andrew Carnegie of New York, the Savings Bank, and the British Linen Company's Bank are all worthy of notice. But the most interesting building in the town is the Abbey Church. The western portion is the nave of the cathedral of the Holy Trinity, originally erected in the massive Norman style by Malcolm Canmore about the middle of the 11th century; it escaped destruction when the rest of the building was demolished by the Reformers on 28th March 1560, served as the parish church till the present century, and now forms a fine vestibule to the New Church. Extensive reparations have been made by the Commissioners of the Woods and Forests, and a number of stained glass windows have been contributed by private individuals. The eastern portion, or New Church—opened for public worship on 30th Sept. 1821—occupies the site of the ancient chancel and transepts, but does not agree in proportions or style with the original edifice. Exactly below the pulpit lie the remains of King Robert Bruce; in the north transept are buried seven other kings, two queens, and numbers of the nobility; and in the southern transept, above the vault of the Elgin family, are

monuments in white marble to the Hon. Robert Bruce, tutor to the prince of Wales, and Charles Dashwood Bruce, cousin of the late Lord Elgin, as well as a bust in marble erected by Dean Stanley in memory of his wife Lady Augusta Bruce. The tomb of Queen Margaret, the wife of Malcolm Canmore, lies immediately to the east of the session-house. Of the ancient abbey buildings there still remains the south wall of the Refectory, or Fraters' Hall, with an entire window much admired for its elegant and complicated workmanship. The south-west wall of the palace still stands in testimony of its former stateliness, and an apartment is pointed out by tradition as the spot where Charles I. was born. There are also some slight traces of an ancient tower popularly ascribed to Malcolm Canmore, but in all probability not of so early a date.

Dunfermline has three Established churches, four United Presbyterian, three Free, one Congregational, one Episcopalian, one Evangelical Union, and one Roman Catholic, as well as several places of worship belonging to smaller denominations. The Queen Anne Street United Presbyterian Church was founded by Ralph Erskine, and the Gillespie church by George Gillespie. The former of these two great dissenters is commemorated by a statue in front of his church, and a sarcophagus over his grave in the abbey churchyard, to the memory of the latter a marble mural tablet is inserted above his resting-place within the abbey. The town is well supplied with means of education in all the ordinary branches; but there is no special provision for the higher departments of learning.

The staple industry of Dunfermline is the manufacture of table-linens, and in this department it has almost no rival. The weaving of damask was introduced into the town in 1718 by a Mr James Blake, who had succeeded in getting possession of the jealously guarded secret in workshops at Drumsheugh, near Edinburgh, to which he obtained access by feigning idiocy. Till about 1845 the bulk of the population were engaged on handlooms, but at present only a comparatively small number earn a scanty and precarious subsistence by the old method. The eleven power-loom factories in the town in 1877 give employment to about 5000 persons, of whom a large proportion are females. The annual value of the goods manufactured is about £850,000. Iron and brass foundries, soapworks, and dyeworks are among the minor industrial establishments, and in the vicinity there are about 22 collieries.

Dunfermline returns a member to Parliament in conjunction with Stirling, Inverkeithing, and Culross. The population of the town was 14,963 in 1871, and is now (1877) 15,839; that of the parish, which, besides the strictly rural district around, includes Limekilns and Charleston, with several colliery districts, was 23,123 in 1871, and is now 24,329. The town is governed by a council consisting of 22 members, including a provost, four bailies, and other officials. The revenue of the town, derived principally from coal-fields, was £7875 in 1876. The number of inhabited houses is 1638; the annual value of real property, £56,038. There are two newspapers published weekly, and four banks, besides the National Savings Bank.

In spite of the introduction in 1850 of an apparently abundant supply of spring water, a scarcity has since been felt in dry seasons; and accordingly at present (1877) works are in progress to effect a communication with the River Devon. It is anticipated that the cost of these will be nearly £60,000. Drainage works are also being constructed, at an estimated cost of £9000, to convey the sewage of the city to the sea at Limekilns. The situation of Dunfermline is very favourable to health: the birth rate is 40 per thousand, the rate of mortality 18.4, and the marriage rate 8.7.

Dunfermline derives its name, "The Town or Fort on the crooked Linn," from the ravine already mentioned. From an early period it was a favourite royal residence, and in 1070 Malcolm III. was there married to Margaret. The Culdees are supposed to have had an establishment in the place, and the Benedictine priory, founded by Canmore, was raised to the rank of an abbey under David I., who bestowed numerous privileges on the community. In 1244 the abbot received a mitre, and in 1249 Queen Margaret, the patron saint, was canonized. During the winter of 1303 the court of Edward I. of England was held in the abbey, and on his departure next year most of the buildings were destroyed by fire. In 1329 King Robert Bruce was interred in the choir of the church. The last royal occupant of the palace was Charles II., who there signed the National League and Covenant. Shortly after the town was plundered by Cromwell's soldiers.

DUNFERMLINE, LORD. See **ABERCROMBY**

DUNGANNON, a parliamentary borough and market-town of Ireland, in the county of Tyrone, standing on an acclivity 8 miles W. of the south-western shore of Lough Neagh, and 94 miles N.W. of Dublin. It consists of a square with diverging streets, and is generally well built. The only public buildings of note are the parish church, with an octagonal spire, a court-house, a market hall, and a college founded by Charles I. Linens are manufactured and coarse earthenware. The town also contains a power-loom weaving manufactory and flour mills. It returns one member to Parliament. The early history of the place is identified with the once powerful family of the O'Neals, whose chief residence was there. In Dungannon the independence of the Irish Parliament was proclaimed in 1782. The population in 1871 was 3886, of whom 55 per cent. were Roman Catholics, area, 230 acres.

DUNGARVAN, a parliamentary borough, market-town, and seaport of Ireland, in the county Waterford, 125 miles S.W. of Dublin. It is situated on the Bay of Dungarvan, at the mouth of the Colligan, which divides the town into two parts, connected by a bridge of a single arch. The eastern suburb is called Abbeyside, where the remains of an ancient keep, erected by the M'Graths still exists. The town contains a town hall, a sessions house, a union work-house, a market house, and barracks. Brewing is carried on to a small extent, and there is a steam mill. The borough returns one member to Parliament. Area of town, 392 acres; of borough, 8499 acres. Population of borough (1871), 7719, of whom 36 per cent. were Roman Catholics.

DUNKELD, a burgh of barony and market-town of Perthshire, Scotland, situated on the north bank of the Tay, 15 miles N.N.W. from Perth. The river is crossed there by a fine bridge of seven arches, begun in 1805 and completed in 1808, at a cost of £42,000. With the exception of the town-hall (erected 1877) and some other modern buildings, the village consists of narrow and ill-built streets presenting an antiquated aspect. It is buried among the dark shades of luxuriant trees, and stands in the centre of a valley surrounded by mountains of considerable elevation, which are wooded to their summits. The river, the bridge, the surrounding mountains, and the remains of an ancient cathedral combine to give the town a very romantic appearance. As early as 729 the Culdees had a monastery at Dunkeld, which was converted into a cathedral by David I. in 1127. Its architecture is of a composite character, exhibiting features both of the Norman and Pointed styles. The centre of the nave is 120 feet by 60, the walls are 40 feet high, and the aisles 12 feet wide. The choir was founded by Bishop Sinclair in 1350; and the tower, which is about 90 feet high, was begun by Bishop Jauder in 1469, and completed by Bishop Brown in 1501. It contains four bells. The cathedral was unroofed at the Reformation, but the choir has been rebuilt, and is now used as the parish church. Beneath the charter-house is the sepulchral vault of the Athole family. In the porch of the church is the tomb of Alexander Stuart, earl of Buchan,

better known as the Wolf of Badenoch, who died in 1394. The most famous of the bishops of Dunkeld was Gavin Douglas, the translator of the *Æneid*. Immediately behind the cathedral stands Dunkeld House, the mansion of the dukes of Athole. The grounds of the ducal residence (which are extensive and picturesque) contain two of the earliest larch trees introduced into Britain, they were brought from Tyrol in 1738. A mile south of Dunkeld, on the other side of the Tay, is the modern village of Birnam, which has sprung up at the railway station. It lies at the foot of Birnam hill, said to derive its name from the famous wood connected with the fate of Macbeth. The population of the burgh in 1871 was 783.

DUNKERS, or **TUNKERS**, a sect of American Baptists originating in Germany. The name, as its second form indicates, is a nickname meaning *dippers*, from the German *tunken*, to dip. From the first the members recognized no other name than "Brethren." The founder of the sect was Alexander Mack of Schwartzenu, who, along with one or two companions, was led to adopt anti-pædobaptist views about the year 1708. It had scarcely assumed organized existence in Germany when its members were compelled by persecution to take refuge in Holland, from which they emigrated to Pennsylvania in small companies in the years between 1720 and 1729. Their first community was established at Germantown, not far from Philadelphia, and other settlements were gradually formed in New England, Maryland, Virginia, Ohio, and Indiana. In the early history of the sect the sexes dwelt apart, and marriage, while not forbidden, was discouraged. Similarly, while the holding of private property was not absolutely prohibited, a certain community of goods was established and maintained by the voluntary action of the members, and it was considered unlawful to take interest for money. These features have now disappeared, but in other respects the sect retains much of its original character. Every member has the right to exhort and take part in the religious services, and for a considerable period no special provision was made for the conduct of worship. There is now, however, a recognized unpaid ministry of bishops and teachers. There are also deacons and deaconesses. In baptism true immersion is used. The Lord's Supper is observed in the evening only, and connected with it are the *lavapedium*, or ceremonial feet washing, and the apostolic "love-feasts." Putting a literal interpretation on James v. 14, they practise the anointing with oil for the healing of the sick, and many of them will not adopt any other means of recovery. They resemble the Quakers in their plainness of speech and dress, and their refusal to take oaths or to serve in war. Their number, which at one time was estimated at 30,000, has very considerably declined, and the latest account states it at less than 8000. An early offshoot from the general body of Dunkers were the Seventh Day Dunkers, whose distinctive principle, as their name imports, was that the seventh day, and not the first day, of the week was the true Sabbath intended to be perpetually and universally observed. Their founder was Conrad Peyso, one of the first emigrants, who established a settlement at "Ephrata," about fifty miles from Philadelphia, in 1733. This branch of the sect has almost died out.

DUNKIRK, or **DUNKERQUE**, a strongly fortified seaport town of France, and capital of an arrondissement in the department of Nord, is situated on the Straits of Dover. 40 miles N.W. from Lille, and 194 N. from Paris, in 51° 2' N. lat. and 2° 22' 32" E. long. It is a well-built town, the streets being large, wide, and regular. It is divided into three parts—(1) the town proper, which is the centre of trade, (2) the low town, containing the principal industries, and (3) the citadel, including docks and granaries, and containing the houses of labourers and sailors. Dunkirk is both a naval port and

one of the merchant ports of Paris, and has two harbours, its maritime trade employing about 5000 vessels with a tonnage of 270,000. The docks occupy about 100 acres. It possesses sugar refineries, starch manufactories, distilleries, foundries, and large ship-building yards. The fisheries of the coast are valuable and extensive. The public buildings most worthy of notice are the church of St Eloi, reconstructed about 1560 in the Gothic style, with a Corinthian peristyle built in 1783; the lighthouse, 170 feet high; the Beffroi, 300 feet high, surmounted with signals for vessels in distress, and containing a celebrated peal of bells; the exchange, the second story of which is a gallery for pictures, statuary, medals, and curiosities; and the theatre. The principal square contains the statue of Jean Bart by David of Angers.

Dunkirk is said to have originated in a chapel founded by St Eloi in the 7th century, round which a small village speedily sprang up. In the 10th century Baldwin III., count of Flanders, raised it to the rank of a town. In 1358 it was burned by the English, and in the 16th century Charles V. built a tower for its defence, of which no traces now remain. In 1553 the English, who had for some time held the town, were expelled from it by the French, who in the ensuing year surrendered it to the Spaniards. In 1646 it once more passed into the hands of the French, who, after a few years' occupation of it, again restored it to Spain. In 1658 it was retaken by the French and made over to the English. After the Restoration, Charles II., being in money difficulties, sold it to the French king Louis XIV., who fortified it. In 1793 it was attacked by the English under the duke of York, who, however, were compelled to retire from its walls with severe loss. The population in 1872 was 34,342.

DUNKIRK, a lake-port town of the United States, in Chautauqua county, New York, situated on a small bay in Lake Erie, 40 miles south-west of Buffalo. It is an important station on the Lake railroad, and forms the western terminus of the Erie line; and by means of the Carrolton railroad it has connection with the Pennsylvania coal-fields. The town occupies an elevated and agreeable position on the lake, and its harbour is free of ice earlier in the spring than the neighbouring port of Buffalo. The industries of the place comprise oil-refining, and the manufacture of glue, flour, and iron-work. Population (1870), 5231.

DUNMOW, GREAT, a market-town of England, in Essex, situated on a *via militaris*, some remains of which still exist. It consists of two good streets, built on an acclivity near the right bank of the Chelmer, 40 miles north-east of London by rail. Its public buildings include a town hall and a literary institute, besides the parish church of St Mary the Virgin, recently restored. Population in 1871, 2983. Two miles to the east is the village of Little Dunmow (population, 359), formerly the seat of a priory remarkable for the custom of presenting a fitch of bacon to any couple who could satisfy a jury of six bachelors and six maidens that they had spent the first year of married life in perfect harmony, and had never at any moment wished they had married. The institution of this strange matrimonial prize—which had its parallel at Whitchanoure (or Winchnor) in Staffordshire, at St Meleine in Brittany, and apparently also at Vienna—appears to date from the reign of John; and the only instances recorded of its award occurred in 1445, 1467, 1701, 1751, and 1763. A revival of the custom was effected in 1855 by Mr Harrison Ainsworth, but the scene of the ceremony was transferred to the town-hall of Great Dunmow. For details see Chambers's *Book of Days*, vol. ii. p. 748-751; and W. Andrews, *History of the Dunmow Fitch of Bacon Customs*, 1877.

DUNNING, JOHN, BARON ASHBURTON (1731-1783), an eminent English lawyer, the second son of John Dunning of Ashburton, Devonshire, an attorney, was born at Ashburton, October 18, 1731, and was educated at the free grammar-school of his native place, where he distinguished himself in classics and mathematics. On leaving school he was taken into his father's office, where he remained until

the age of nineteen, when he was sent to the Temple. Called to the bar in 1756, he came very slowly into practice. He went the Western Circuit for several years without receiving a single brief. In 1762 he was employed to draw up *A Defence of the United Company of Merchants of England trading to the East Indies, and their Servants, particularly those at Bengal, against the Complaints of the Dutch East India Company to his Majesty on that subject*; and the masterly style which characterized the document procured him at once reputation and emolument. In 1763 he distinguished himself as counsel on the side of Wilkes, whose cause he conducted throughout. His powerful argument against the validity of general warrants (18th June 1763) established his reputation, and his professional business from that period gradually increased to such an extent that in 1776 he is said to have been in the receipt of nearly £10,000 per annum. In 1766 he was chosen recorder of Bristol, and in December 1767 he was appointed solicitor-general. The latter appointment he held till May 1770, when he retired, along with his friend Lord Shelburne. In 1771 he was presented with the freedom of the city of London. From this period he was considered as a regular member of the Opposition, and distinguished himself by many able speeches in Parliament. He was first chosen member for Calne in 1768, and continued to represent that burgh until he was promoted to the peerage. In 1780 he brought forward a motion that the "influence of the crown had increased, was increasing, and ought to be diminished," which he carried by a majority of eighteen. He strongly opposed the system of sinecure offices and pensions; but his probity was not strong enough to prevent his taking advantage of it for himself. In 1782, when the marquis of Rockingham became prime minister, Dunning was appointed chancellor of the duchy of Lancaster, a rich sinecure; and about the same time he was advanced to the peerage, by the title of Lord Ashburton. Under Lord Shelburne's administration he accepted a pension of £4000 a year. He died while on a visit to Exmouth, August 18, 1783. Though possessed of an insignificant person, an awkward manner, and a provincial accent, Lord Ashburton was one of the most fluent and persuasive orators of his time. Sir William Jones speaks in the highest terms of his eloquence and wit, and Bentham commended the closeness of his reasoning.

Besides the answer to the Dutch memorial, Lord Ashburton is supposed to have assisted in writing a pamphlet on the law of libel, and to have been the author of *A Letter to the Proprietors of East India Stock, on the subject of Lord Clive's Jaghire, occasioned by his Lordship's Letter on that Subject*, 1764, 8vo. He was at one time suspected of being the author of the celebrated *Letters of Junius*.

DUNOIS, JEAN (1402-1468), Count of Orleans and Longueville, commonly called the "Bastard of Orleans," a celebrated French warrior and grand-chamberlain of France, was the natural son of the duke of Orleans (brother of Charles VI.) and Mariette d'Enghien, Madame de Cergy, and was born at Paris the 23d November 1402. He was brought up in the house of the duke, and in the company of his legitimate sons. His earliest feat of arms was the surprise and rout in 1427 of the English, who were besieging Montargis,—the first successful blow against the English power in France following a long series of French defeats. In 1428 he threw himself into Orleans, and was the principal means of enabling the garrison to hold out until the arrival of Joan of Arc, when he shared with her the honour of defeating the enemy there in 1429. He then accompanied Joan to Rheims, and shared in the victory of Patay. After her death he raised the siege of Chartres and of Lagny, and drove the English from Paris, which he entered in triumph on the 13th April 1436. The English retreated gradually into the Isle of France, and thence into Normandy; and Dunois, having in 1449 been raised to the rank of lieutenant-general, soon conquered from them the whole

of that province. In 1451 he attacked them in Gurenne, taking among other towns Bordeaux, which the English had held for 300 years. At the conclusion of these conquests Charles VII. legitimated him, and gave him the title of defender of his country, and the office of grand chamberlain, but on the death of Charles, Louis XI. deprived him of his titles and dignities. He then joined the league of revolted princes, but, assuming the function of negotiator, and thus securing the favour of the king, he was reinstated in his offices, and named president of the council for the reform of the state. He died 28th November 1468.

DUNOON, a town in Argyllshire, Scotland, situated on the Firth of Clyde, about nine miles west from Greenock, and on the opposite shore. Of recent growth (having been about the beginning of this century a mere fishing hamlet), it is now one of the most extensive and prosperous watering-places on the shores of the Clyde, a condition for which it is much indebted to the late James Ewing of Strathleven, who first drew attention to its capabilities as an agreeable summer residence. On account of the mildness of the climate that prevails, and the amenity of the situation, it was selected as the site of a convalescent home, which has proved a boon to many of the hard-wrought population of Glasgow and its neighbourhood. On a conical hill close above the main pier stand the fragments of Dunoon Castle, the hereditary keepership of which was conferred by Robert Bruce on the family of Sir Colin Campbell of Loch Awe, an ancestor of the duke of Argyll. Near the hillock is the modern castle of Dunoon. Including the suburb of Kilm, the population at the census of 1871 was 3750.

DUNS SCOTUS, JOHN, one of the foremost of the schoolmen, was born in the latter half of the 13th century. The year and place of his birth are both uncertain. For the date 1265 and 1275 have been assigned, without any decisive evidence in favour of either. The form of the surname seems to support the claim of Dunse, in Berwickshire, as the place, though the same ground has been pled, with less plausibility it must be admitted, for Downpatrick (Dunum) in Ireland, and for the village of Dunstane in Northumberland. In favour of Dunstane a statement at the close of a manuscript copy of the work of Duns Scotus, contained in the library of Merton College, Oxford, has been quoted; but this, though it states expressly that the author was born at Dunstane, is inconclusive. The rival claims of England, Scotland, and Ireland have been naturally enough advocated by natives of the three countries respectively, Leland, Dempster, and Wadding, and have been the subject of considerable controversy, into which it would be a waste of time to enter. It is noteworthy, however, as a curiosity of literature, that Dempster published a quarto volume, the main object of which was to prove by twelve distinct arguments that Duns Scotus was a Scotchman. It is said that when he was a boy his extraordinary ability was observed by two Franciscan friars, who took him to their convent at Newcastle. Whether this be so or not it seems certain that he joined the Franciscan order in early life, and that he studied at Merton College, Oxford, of which he was made a fellow. According to Wadding, he became remarkably proficient in all branches of learning, but especially in mathematics. When his master, William Varron, removed to Paris in 1301, Duns Scotus was appointed to succeed him as professor of philosophy. His lectures attracted an immense number of students, though the story that in his day the university was attended by no less than 30,000 is probably a gross exaggeration. He was removed to Paris, probably in 1304, though the precise date is uncertain. In 1307 he received his doctor's degree from the university of Paris, and in the same year he was appointed regent of the theological school. His connection with the university was made memorable by his defence of the doctrine of the Immaculate Concep-

tion, in which he displayed such dialectical ingenuity as to win for himself the title *Doctor Subtilis*. According to the account that is usually given he refuted one by one no less than two hundred objections urged against the doctrine by the Dominicans, and established his own position by "a cloud" of arguments. The doctrine continued long to be one of the main subjects in dispute between the Scotists and the Thomists, or, what is almost the same thing, between the Franciscans and the Dominicans. To judge from its subsequent acts, the university of Paris seems to have been deeply and lastingly impressed by the arguments of Duns Scotus. In 1387 it formally condemned the Thomist doctrine, and a century afterwards it required all who received the doctor's degree to bind themselves by an oath to defend the doctrine of the Immaculate Conception. In 1308 Duns Scotus was sent by the general of his order to Cologne with the twofold object of engaging in a controversy with the Beghards and of assisting in the foundation of a university. He was received with great ceremony by the magistrates and nobles of the city. After a very short residence, however, he died of apoplexy on the 8th November 1308. The story told by Paulus Jovius, that on his grave being opened some time after his death his body was found to have turned in the coffin, from which it was inferred that he had been buried alive, is generally regarded as fabulous.

Duns Scotus was one of the great leaders of scholastic thought, and, as a full account of his philosophical system must therefore necessarily be given in the general article on SCHOLASTICISM, a brief indication of its leading points will suffice here. It may be noted, at the outset that the philosophical position of Duns Scotus was determined, or at least very greatly influenced, by the antagonism that existed between the Dominicans and the Franciscans. Thomas Aquinas was a Dominican, Duns Scotus was a Franciscan; and hence arose the schism between the Thomists and the Scotists. Aquinas ranks in philosophy with the realists as well as Duns Scotus, but his view in regard to the great philosophical controversy of the Middle Ages was a modified or eclectic one in comparison with that of Duns Scotus, who is the true representative and apostle of scholastic realism. Theologically, the doctrine of the Immaculate Conception was the great subject in dispute between the two parties. There were, however, differences of a wider and deeper kind. In opposition to Aquinas, who maintained that reason and revelation were two independent sources of knowledge, Duns Scotus held that there was no true knowledge of anything knowable apart from theology as based upon revelation. In conformity with this principle he denied that the existence of God was capable of being proved, or that the nature of God was capable of being comprehended. He therefore rejected as worthless the ontological proof offered by Aquinas. Another chief point of difference with Aquinas was in regard to the freedom of the will, which Duns Scotus maintained absolutely. He held also in an unqualified form the doctrine of predestination, and he reconciled free-will and necessity by representing the divine decree not as temporally antecedent, but as immediately related to the action of the created will. He maintained, in opposition to Aquinas, that the will was independent of the understanding, that only will could affect will. From this difference as to the nature of free-will followed by necessary consequence a difference with the Thomists as to the operation of divine grace. In ethics the distinction he drew between natural and theological virtues is common to him with the rest of the schoolmen, among others with his great opponent (See AQUINAS, vol. ii. p. 232-3). Duns Scotus strongly upheld the authority of the church, making it the ultimate authority on which that of Scripture depends.

The works of Duns Scotus were very numerous, though in the collection edited by Luko Wadding, a Franciscan (12 vols. fol., Lyons, 1639), several are ascribed to him without sufficient ground. This edition contains a life full of legends, which was reprinted separately (Mons, 1644). The most important of the works of Duns Scotus consisted of questions and commentaries on the writings of Aristotle, and on the *Sentences* of Lombard.

For the theology of Scotus see the *Summa Theologica ex Scoti Operibus*, by Jerome de Fortius, a Franciscan, the *Resolutio doctrine Scoticae*, by F. E. Albergoni (Lyons, 1643), and the *Controversiae theologiae inter S. Thomam et Scotum*, by De Rada, a Spanish Franciscan (Venice, 1599). Of more recent authorities particular value attaches to Baumgarten-Crusius's *De Theologia Scoti* (Jena, 1826) and an article by Erdmann in the *Theologische Studien und Kritiken* for 1863. On the philosophy of Duns Scotus see Ritter's *Geschichte der Philosophie* and Ueberweg's *Geschichte der Philosophie*.

DUNSTABLE, a market-town and, since 1864, a municipal borough of England, in the county of Bedford, 33 miles N.W. of London, and 18 miles S.S.W. of Bedford, with communication by both the North-Western and the Great Northern railways. Its parish church, a fine old building, formerly part of the Augustinian priory, was restored about 1865, the principal points of interest are the richly decorated west front, the ancient monuments of the Chew family, and, among the interior adornments, Sir James Thornhill's painting of the Last Supper. The five dissenting churches, the temperance hall, several alms-houses, and the Ashton charity and other schools complete the list of public buildings. Straw-plaiting and the making of straw hats and bonnets are the principal industries, and, as a consequence, the female considerably outnumbers the male population. The census of 1861 gave 2712 females out of a total of 4470 inhabitants, and that of 1871, 2702 out of 4558.

From its situation at the junction of the ancient Watling and Icknield Streets, it seems probable that Dunstable was a Roman station, but its identification, whether with Magiovinium or Duracobrive, is not certainly established. Matthew Paris mentions, in his *Lives of the Abbots of St. Albans*, that about 1110 the play of S. Katharina was acted in the town by direction of Geoffrey, afterwards abbot of St. Albans, and thus the name of Dunstable is associated with the very earliest authentic notice of theatrical representation in England. The Augustinian priory, to which it was afterwards indebted for its celebrity, was founded in 1131 by Henry I., and for a long period exercised lordship over the town. From 1227 to 1229 there was a violent dispute between the burghers and the canons, but the claims of the latter were acknowledged by Hubert de Burgh, the justiciary. It was at Dunstable that in 1244 the discontented barons met and ordered the papal nuncio to leave the kingdom, and in 1538 the commissioners for the divorce of Queen Catherine sat in the priory. The *Annales de Dunstaplia* are one of the most valuable of the monastic chronicles still extant. They extend from the incarnation to the year 1297, and are fortunately fullest in the account of contemporary events. The entries from 1210 to 1242 are due to Richard de Morins, the prior. The original is a parchment folio preserved among the Cotton MSS. in the British Museum (Tiberius, A. 10). It was greatly damaged by the fire of 1731, and is consequently slightly imperfect, in spite of the care with which it has been stretched and mended. Hearne published an edition in 1733 from a fairly accurate transcript by Humphrey Wanley (Harleian MSS. 4886), another by H. R. Luard, from the original MS., occupies 420 pages of vol. iii. of the *Annales Monastici*, published by the Master of the Rolls.

DUNSTAN, St. (924 or 925–988), was born at Glastonbury in 924 or 925. His father, Hcorstan, was brother of Ælfheah the Bold, bishop of Winchester; and the tradition that he was connected with the royal house seems not improbable. As a child he was placed under the care of certain Irish teachers who had settled at Glastonbury; and he devoted his boyhood to study with a fervour so intense that he at length brought on himself a severe attack of brain fever, the effects of which are apparent in the fantastic visions which troubled his after life. He was still a boy when he entered the household of Athelstan, and he was only fifteen or sixteen at the acces-

sion of Edmund; but he had not been long at court before his ambitious and lofty temper had surrounded him with bitter enemies. In all the accomplishments of his time, except those of the warrior, he stood pre-eminent. His memory was stored with the ancient Irish ballads and legends, and he excelled in music, in painting, and even in the mechanical arts. But he soon found that his talents, while making him a favourite in the ladies' bowers, only inflamed the jealousy of his rough, ignorant soldier rivals. He was accused of dealing in witchcraft, was driven with rude force from the court, and, perhaps under the pretext of testing whether he was really wizard or no, was flung into a muddy pond, whence he was glad to escape to the protection of his uncle Ælfheah. The result of this outrage was a second attack of fever, from which he rose to yield to his uncle's persuasions, and take the vows as a monk. It was with great reluctance that he took this step, for he was deeply in love with a lady at court; but the feeling, natural in that age, that his illness was a direct indication of the will of providence, was likely to impress itself with peculiar force upon an imagination such as his, and he was also, doubtless, conscious that the only protection for his physical weakness lay in the power of the church. After his recovery, he spent some time quietly studying and teaching, and practising the austerities which gained him the reputation of a saint; but it was not long before he returned to court. Again his enemies seemed likely to prove too powerful for him. He, however, gained the favour of King Edmund, who created him abbot of Glastonbury when he was about twenty-two years of age. He became principal treasurer of the kingdom, and we find him a few years later (953), on account of his tenure of that office, refusing an offer of the see of Crediton.

From 946 to 955 the throne was occupied by Edred, whose constant ill health threw the chief power into Dunstan's hands. In 955 Edwy came to the throne; and the party of Edgiva, to which Dunstan belonged, lost its influence. Of the details of the party struggles which ensued we have no trustworthy information; but one incident of the quarrel between the king and the minister has become famous. Edwy, though then probably a mere boy, was deeply in love with his kinswoman Elgiva, whose mother Ethelgiva, a lady of the highest rank, is accused, with what degree of truth cannot now be determined, of having used the most shameful means to gain power over the young king. What relationship really existed between Edwy and Elgiva is unknown, but it was such as to be considered by the churchmen as an insuperable bar to marriage. Edwy, however, defied their opposition. On the evening of his coronation he withdrew from the banquet to the society of Elgiva. Dunstan was sent by the Witan to recall him, and exhibited a violence which may be excused, when we consider that Edwy had both grievously insulted the Witan and openly sought, upon so solemn an occasion, the dangerous society of a girl whom the church forbade him to marry.

A year or so after Ethelgiva and her party triumphed, and Dunstan being outlawed, was obliged to flee to Ghent. In 957, however, a revolt placed Edwy's brother Edgar on the throne of Mercia and Northumbria, and at his court Dunstan resumed his old position of chief minister. He was created bishop (perhaps at first without a see); and, in defiance of strict ecclesiastical law, he obtained and held at once the sees of Worcester and London. By the death of Edwy in 959, Edgar gained the sovereignty of Wessex, and a few months after Dunstan was appointed archbishop of Canterbury¹. On the death of Edgar (955),

¹ In connection with the coronation of Edgar, Osbern of Canterbury tells a story intended to exalt the archbishop. The king having

Dunstan's influence secured the crown for Edward. But a fierce struggle ensued between Dunstan and his enemies. In 977 the Witan met three times; and the last meeting, that at Calne, was signalized by an accident, which the friends of Dunstan called a miracle. Half the floor of the room in which the Witan was assembled gave way at the moment that Dunstan was making a solemn appeal to God, so that the enemies of Dunstan fell, and Dunstan and his friends remained unhurt. This accident has been explained by reference to the archbishop's well-known skill in mechanics. During the first few years of the unhappy reign of Ethelred the Unready, Dunstan probably retained some influence in the government; and it is noteworthy that the year of his death (which took place on the 19th May 988) marks the commencement of the most disastrous invasions of the Danes. Towards the close of his life Dunstan is said to have retired from the court, and his last years were devoted to religious observances and the composition of sacred music, his favourite amusement being, as of old, the manufacture of bells and musical instruments.

Dunstan has been frequently painted by historians as one of the most complete types of the bigoted ecclesiastic. If, however, we critically examine the best sources, he will appear to have been statesman much more than ecclesiastic; and the circumstances which caused him to be honoured by the monks as one of their greatest patrons will become manifest. Even in his lifetime he was believed to be endowed with supernatural power, as is shown by the charge of witchcraft brought against him in his youth, and by the story of the miracle at Calne. His earliest biography, written by a contemporary, represents him as a man of vivid imagination, a seer of visions and dreamer of dreams, a man of unusually sensitive nervous organization, as is indicated by the strange "gift of tears" with which he is said to have been endowed; and in this biography we find the first of the tales which became so common of his interviews with the devil, who is said to have tormented him in the form of a bear and in other frightful shapes. By a very common process, there came to be connected with his name a large number of marvellous legends, of which the best known is the story of how the devil appeared to him with impure suggestions while he was working at his forge, and how the saint retaliated by seizing the nose of the great enemy with a pair of red-hot tongs. It is not surprising that the monkish writers should exaggerate any services rendered to their order by an archbishop possessed of so wonderful a reputation. But in fact there is good reason to believe that Dunstan always treated church affairs as subordinate to political considerations. While Ethelwald, the bishop of Winchester, and Oswald, bishop of Worcester, and afterwards archbishop of York, were introducing monks of the strict Benedictine order into their sees in place of the seculars, and doing their utmost to enforce celibacy among the clergy, he allowed the married priests to retain their places in his diocese without interference. On the other hand, no doubt all Dunstan's influence in church affairs was given to the monastic party, though that influence was exerted with a statesman-like moderation for which he has not received credit, and it is likely that he did not attain his canonization without performing substantial service to the church. The political services which Dunstan rendered to England were certainly of the first importance. He guided the state successfully during the nine years reign of the invalid Edred. And there is good

reason to believe that he deserves at least as much credit as the king himself for the settlement of Northumbria and the Danes which was effected, for the peace which prevailed, and the glory which was gained, in Edgar's famous reign.

Several works have been attributed to Dunstan, including a commentary on the Benedictine rule, and a *Regularis Concordia* (published in Reyner's *Apostolatus Benedictinorum* and in the *New Monasticon*); but the real authorship of both of these is doubtful. His reputation as a miracle-worker so long outlasted his life, that a tract on the philosopher's stone was published in his name at Cassel in 1649.

The earliest and the most trustworthy of the biographers of Dunstan was "the priest B," whom some authorities have supposed, though not upon conclusive grounds, to be the scholar Bridferth of Ramsey.¹ The date of his work is fixed by Prof Stubbs at about 1000, it is dedicated to archbishop Elfric who died in 1006. The later lives,—those of Adelard (which consists of lessons intended to be used in the monasteries), of Osbern, Eadmer, and William of Malmesbury,—are of far less value, being distorted by prejudice and filled with extravagant legends. The *Memorials of Saint Dunstan* have been published by Mabillon, and also in the *Master of the Rolls' series*, edited, with an introduction, by Prof Stubbs. A scholarly essay on *Dunstan and his Policy* is contained in Mr E. W. Robertson's *Historical Essays*, and the life of Dunstan is included in Dean Hook's *Lives of the Archbishops of Canterbury* (T. M. W.)

DUNTON, JOHN (1659–1735) an eccentric bookseller, publisher, and author, was born at Grafton, in Huntingdonshire, May 4, 1659. In his boyhood he showed great fondness for adventure, and a faculty for getting into and out of scrapes. At the age of fifteen he was apprenticed to Thomas Parkhurst, bookseller, at the sign of the Bible and Three Crowns, Cheapside, London, whose strictness had full exercise in the endeavour to keep in check his wayward tendencies. During the struggle which led to the Revolution, Dunton joined the Whig apprentices, and became the treasurer of that body. In 1685 he became bookseller at the sign of the Raven, near the Royal Exchange, having, after much consideration as to the lady he should select, married a sister of Samuel Wesley. His wife managed his business, so that he was left free in a great measure to follow his own eccentric devices, which now took the form chiefly of writing and rambling. In 1686, probably because he was concerned in the Monmouth rising, he visited New England, where he stayed eight months selling books and observing with interest the new country and its inhabitants. He then made a short excursion to Holland after which, returning to England, he opened a new shop in the Poultry, in the hope of better times. Here he published weekly the *Athenian Mercury*, which professed to answer all questions on history, philosophy, love, marriage, and things in general. It enjoyed considerable popularity for some time, but he discontinued it, after a course of six years, in 1696. His wife died some time after this. He married a second time; but a quarrel about his wife's property led to a separation, and, having no one to manage his affairs, he spent the remainder of his life in great poverty. He died in 1735. He wrote a great many books which are now forgotten, but his *Life and Errors*, on account of its naïveté and as a picture of bygone times, is still read, and his letters from New England were published in America in 1867.

DUPERREX, LOUIS ISIDORE (1786–1865), a French navigator and scientific investigator, was born at Paris, entered the navy in 1803, took part in the military operations of 1809 at Brest and Rochefort, and assisted in the hydrographical survey of the coast of Tuscany carried on during that and the following year. From 1817 to 1820 he served under Freycinet in his great voyage round the world, being intrusted with the hydrographic operations on board the "Urania;" and he contributed largely to the preservation of the crew and the scientific collections when

taken the nun afterwards called St Wulfrith as his mistress, Dunstan is said to have vindicated the independence of the church by forbidding him, among other penances, to wear the crown for seven years; but there are several reasons for doubting this story. The question is elaborately discussed in the article on the "Coronation of Edgar," in Mr E. W. Robertson's *Historical Essays*.

¹ This question is fully discussed by Prof Stubbs in his Introduction to the *Memorials of Saint Dunstan*, but there are no sufficient data for discovering the author.

his vessel was wrecked at the Malouin Islands. In 1822 he attained the rank of lieutenant, and was intrusted with the command of the "Coquille," which during the next three years was engaged in scientific explorations in the South Pacific and along the coasts of South America. From this voyage he brought back not only great additions to cartography and important data in regard to the currents of the Pacific, but also numerous pendulum observations, serving to determine the magnetic equator, and to prove the equality of the flattening of the two hemispheres. During the rest of his life he devoted himself mainly to the investigation of terrestrial magnetism, and the value of his labours was recognized by his admission into the *Académie des Sciences* in 1842. He died in August 1865.

The following are his principal works—*The Partie historique, the Hydrographie, and the Physique of the Voyage autour du Monde sur la Coquille*, Paris 1826–1830, and extensive contributions to Becquerel's *Traité de l'Electricité*.

DUPERRON, JACQUES DAVY (1556–1618), a celebrated French cardinal, was born at St Lô, in Normandy, November 15, 1556. His father was educated for a physician, but on embracing the doctrines of the Reformation became a Protestant minister, and to escape persecution settled at Bern, in Switzerland. Here Jacques Davy received his education, being taught Latin and mathematics by his father, and learning without the aid of any one Greek and Hebrew and the philosophy which was then in vogue. At twenty years of age he came to Paris, and was presented to the king by the count of Matignon; and, after he had abjured Protestantism, being again presented by Philip Desportes, abbot of Tiron, as a young man without equal for knowledge and talent, he was appointed reader to the king. He was commanded to preach before the king at the convent of Vincennes, when the success of his sermon on the love of God, and of a funeral oration on the poet Ronsard, induced him to take orders. On the death of Mary Queen of Scots he was chosen to pronounce her eulogy, which, though it contained an attack on Elizabeth of England that the king thought it prudent to disavow, tended to advance both the ecclesiastic's fame and fortune. When the Cardinal de Bourbon, at the end of Henry III.'s reign, plotted to secure to himself the throne to the prejudice of Henry IV., Duperron is accused of having joined in the plot and revealed to Henry IV. its secrets. However that may be, when the plot failed, and Henry IV. mounted the throne, Duperron enjoyed the favour of that monarch, and in 1591 was created by him bishop of Evreux. He converted Henry to the Catholic religion; and, after the taking of Paris, accompanied the Cardinal d'Ossat to Rome to obtain the removal of the interdiction which had been passed upon France. On his return to his diocese, his zeal and eloquence were largely instrumental in withstanding the progress of Calvinism, and among others he converted Henry Sponde, who became bishop of Pamiers, and the Swiss general Sancy. His success attracted the attention of the church, and he was chosen to represent it at the conference at Fontainebleau in 1600. In 1604 he was sent to Rome as "charge d'affaires de France," and, having hardly arrived when Clement VIII. died, he largely contributed by his eloquence to the election of Leo XI. to the papal throne, and, on the death of Leo twenty-four days after, to the election of Paul V. While still at Rome he was named archbishop of Sens, and the same year was made a cardinal. He died at Paris, Sept. 6, 1618. Duperron was a zealous defender of the infallibility and power of the Pope, and of his superiority over a general council. He was possessed of immense energy, and of a ready and convincing eloquence, which he could make available for whatever opinions he thought it prudent to adopt, and, if he did not

form his opinions solely with a view to his advancement, they certainly adapted themselves in each case with remarkable appropriateness to the different emergencies and turning points of his life. His works were collected after his death, and published in three volumes in 1622–23.

DUPIN, ANDRÉ MARIE JEAN JACQUES (1783–1865), commonly called Dupin the Elder, a celebrated French advocate, president of the Chamber of Deputies and of the Legislative Assembly, was born at Varzy, in Nièvre, on the 1st February 1783. He was educated by his father, who was a lawyer of eminence, and at an early age he became principal clerk of an attorney at Paris. On the establishment of the *Académie de Législation* he entered it as pupil from Nièvre. In 1800 he was made advocate, and in 1802, when the schools of law were opened, he received successively the degrees of licentiate and doctor from the new faculty. He was in 1810 an unsuccessful candidate for the chair of law at Paris, and in 1811 he also failed to obtain the office of advocate-general at the court of cassation. About this time he was added to the commission charged with the classification of the laws of the empire, and, after the interruption caused by the events of 1814 and 1815, was charged with the sole care of that great work. When he entered the Chamber of Deputies in 1815 he at once took an active part in the debates, and strenuously opposed the election of the son of Napoleon as emperor after his father's abdication. At the election after the second restoration Dupin was not re-elected. He defended with great intrepidity the principal political victims of the reaction, among others, in conjunction with Berryer, Marshal Ney, and in October 1815 boldly published a tractate entitled *Libre Défense des Accusés*. In 1827 he was again elected a member of the Chamber of Deputies, and in 1830 took part in counselling the revolution, and in exhorting the citizens to resistance. In August of that year he became a member of Louis Philippe's cabinet, and more than any one else contributed to the formation of the new régime. At the end of 1832 he became president of the chamber, which office he held successively for eight years. On Louis Philippe's abdication in 1848 Dupin introduced the young count of Paris into the chamber, and proposed him as king with the duchess of Orleans as regent. This attempt failed, but Dupin submitted to circumstances, and, retaining the office of *procureur-général*, his first act was to decide that justice should henceforth be rendered to the "name of the French people." In 1849 he was elected a member of the Assembly, and became president of the principal committee—that on legislation. After the *coup d'état* of 2d December 1851 he still retained his office of *procureur-général*, and did not admit it till effect was given to the decrees confiscating the property of the house of Orleans. In 1857 he was offered his old office by the emperor, and accepted it, explaining his acceptance in a discourse, a sentence of which may be employed to describe his whole political career. "I have always," he said, "belonged to France and never to parties." He died 8th November 1865. Among Dupin's works, which are numerous, may be mentioned *Principia Juris Civilis*, 5 vols. (1806), *Mémoires et plaidoyers de 1806 au 1^{er} Janvier 1830*, in 20 vols.; and *Mémoires ou souvenirs du barreau*, in 4 vols. 1855–57.

DUPIN, LOUIS ELLIES (1657–1719), a celebrated French ecclesiastical historian, belonged to a noble family in Normandy, and was born at Paris on the 17th June 1657. He received his early education from his father, and had scarcely reached his tenth year when he entered the college of Harcourt, where he graduated as M.A. in 1672. Determining to adopt the ecclesiastical profession, he became a pupil of the Sorbonne, and received the degree of B.D. in 1680, and that of D.D. in 1684. About this time he conceived the idea of a *Bibliothèque Universelle de tous les*

Auteurs Ecclésiastiques, the first volume of which appeared in 1686. The liberty with which he there treated the doctrines of the fathers aroused ecclesiastical prejudice, and the archbishop of Paris condemned the work. Dupin consented to a retraction, but it was suppressed in 1693, he was, however, allowed again to continue it on changing its title, to the extent of substituting *Nouvelle* for *Universelle*. He was subsequently exiled to Châtellerault as a Jansenist, but the sentence of banishment was repealed on a new retraction. In 1718 he entered into a correspondence with Wake, archbishop of Canterbury, with a view to a union of the English and Gallican churches; and, being suspected of projecting a change in the dogmas of the church, his papers were seized in 1719, but nothing was found that could be properly framed into an accusation against him. The same zeal for union is said to have induced him, during the residence of Peter the Great in France, and at that monarch's request, to draw up a plan for uniting the Greek and Roman churches. He died at Paris on the 6th June 1719.

Dupin was a voluminous author. Besides his great work on ecclesiastical authors, mention may be made of *Bibliothèque Universelle des Historiens*, 2 vols. (1707), *L'Histoire de l'Eglise en abrégé* (1712), and *L'Histoire Profane depuis le commencement du Monde jusqu'à présent*, 4 vols. 1712.

DUPLEIX, JOSEPH, governor-general of the French establishments in India, was born about the close of the 17th century. The son of a rich farmer-general, he was carefully educated, made several voyages to America and India, and in 1720 was named a member of the superior council at Pondicherry. He displayed great business aptitude, and, in addition to his official duties, made large ventures on his own account, and acquired a fortune. In 1730 he was made superintendent of French affairs in Chandernagore, the town prospering under his energetic administration and growing into great importance. His reputation procured him in 1742 the appointment of governor-general of all French establishments in India. His ambition now was to acquire for France vast territories in India, and for this purpose he entered into relations with the native princes, and adopted a style of Oriental gorgeousness in his dress and surroundings. The English took the alarm. But the danger to their settlements and power was partly averted by the bitter mutual jealousy which existed between Dupleix and La Bourdonnais, French governor of the Isle of Bourbon. When Madras capitulated to the French in 1746, Dupleix opposed the restoration of the town to the English, thus violating the treaty signed by La Bourdonnais. He then sent an expedition against Fort St David (1747), which was defeated on its march by the nabob of Arcot, the ally of the English. Dupleix succeeded in gaining over the nabob, and again attempted the capture of Fort St David, but unsuccessfully. A midnight attack on Cuddalore was repulsed with great loss. In 1748 Pondicherry was besieged by the English; but in the course of the operations news arrived of the peace concluded between the French and the English at Aix-la-Chapelle. Dupleix next entered into negotiations which had for their object the subjugation of Southern India, and he sent a large body of troops to the aid of two claimants of the sovereignty of the Carnatic and the Deccan. The English were engaged on the side of their rivals. After temporary successes the scheme failed. The conflicts between the French and the English in India continued till 1754, when Dupleix was recalled to France. He had spent immense sums out of his private fortune on account of the French company, but in opposition to their wishes, and vainly attempted to recover them from the Government. He appears to have died in obscurity and want about 1763.

DUPONT, PIERRE (1821-1871), a French song-writer of great popularity, the son of a workman of Provins, was born at Lyons, his mother's native city, but brought up from childhood under the care of an elderly cousin who occupied the position of priest of Roche-Taillée-snr-Saône. From the seminary of Largentière, where his education was completed, he passed to the uncongenial drudgery of a lawyer's and banker's office; in 1839 found his way to Paris and got some of his poems inserted in the *Gazette de France* and the *Quotidienne*, and two years later was saved from the conscription and enabled to publish his first volume—*Les deux Anges*—through the exertions of a Provins kinsman and M. Lebrun. The prize founded by M. de Maillé La Tour-Landry was awarded to him in 1842, and he was employed for some time in connection with the Academy's great dictionary. The thought of trying his fortune as a writer for the stage was taking shape in his mind, when in 1847 the success of his peasant song *J'ai deux grands bœufs dans mon étable* opened up another prospect of fame; and from that date to his death he confined himself mainly, though not exclusively, to the cultivation of his lyrical faculty. Accompanied, as they often were, by airs of his own invention, many of his songs became in the widest sense popular, and were equally welcome in the workshop and the drawing-room. His sympathies were much less, however, with the drawing-room than the workshop; and in 1851 he paid the penalty of having become the poet laureate of the socialistic aspirations of the time by being condemned to seven years of exile from France. The sentence was cancelled, and the poet withdrew for a season from participation in politics. He died at Paris in 1871. His lyrical poems may very fairly be arranged according to his own classification—rustic and, as far as the writer is concerned, objective, legendary and subjective, patriotic and contemporaneous. They have appeared in various forms—*Chants et Chansons*, 3 vols., with music, 1852-54; *Chants et Poésies*, 7th edition, 1862; &c. Among the best known are *Lé braconnier*, *Le tisserand*, *La vache blanche*, *La chanson du blé*, but many others might be mentioned of equal merit,—natural, bold, delicate, and piquant. *Dix eclogues*, 1864, *Fin de la Pologne*, 1847, *La légende du juif errant*, 1862, written to accompany Doré's engravings, and *Muse juvénile*, 1859, are separate publications.

See Sainte-Beuve, *Causeries du lundi*, vol. iv., where an interesting description is given of the style in which the author sung his own songs in the clubs and political meetings, Cf. Baudelaire, *Notice sur P. Dupont*, 1849; Déchant, *Biographie de Pierre Dupont*, 1871.

DUPONT DE L'EURE, JACQUES CHARLES (1767-1855), a French lawyer and statesman, was born at Neubourg, in Normandy, on the 27th February 1767. In 1789 he was an advocate at the Parliament of Normandy. During the republic and the empire he filled successively judicial offices at Louviers, Rouen, and Evreux. He had adopted the principles of the Revolution, and in 1798 he commenced his political life as a member of the Council of Five Hundred. In 1813 he became a member of the Corps Législatif. During the Hundred Days he was vice-president of the Chamber of Deputies, and when the allied armies entered Paris he distinguished himself by the firmness with which he asserted the necessity of maintaining the principles of government that had been established at the Revolution. A resolution to that effect which he moved in the chamber was adopted, and he was chosen one of the commissioners to negotiate with the allied sovereigns. From 1817 till 1849 he was uninterruptedly a member of the Chamber of Deputies, and he acted consistently with the liberal opposition, of which at more than one crisis he was the virtual leader. For a few months in 1830 he held office as minister of justice, but, finding himself out of harmony with his colleagues, he resigned before the close of the year and

resumed his place in the opposition. At the revolution of 1848 Dupont de l'Eure was made president of the provisional government as being its oldest member. In the following year, having failed to secure his re-election to the chamber, he retired into private life. He died in 1855 at the age of eighty-eight. The consistent firmness with which he adhered to the cause of constitutional liberalism during the many changes of his times gained him the highest respect of his countrymen, by whom he was styled the Aristides of the French tribune.

DUPONT DE NEMOURS, PIERRE SAMUEL (1739–1817), a French political economist and statesman, was born at Paris on the 14th December 1739. He studied for the medical profession, but did not enter upon practice, his attention having been early directed to economic questions through his friendship with Quesnay, Turgot, and other leaders of the school known as the Economists. To this school he rendered valuable service by several pamphlets on financial questions, and numerous articles representing and advocating its views in a popular style in the *Journal de l'Agriculture, du Commerce, et des Finances*, and the *Épémérides du Citoyen*, of which he was successively editor. In 1772 he accepted the office of secretary of the Council of Public Instruction from Stanislas Poniatowski, king of Poland. Two years later he was recalled to his native country by the advent of his friend Turgot to power. After assisting the minister in his wisely-conceived but unavailing schemes of reform during the brief period of his tenure of office, Dupont shared his dismissal and retired to Gâtinais, in the neighbourhood of Nemours, where he employed himself in agricultural improvements. During his leisure he wrote a translation of Ariosto (1781), and *Mémoires sur la vie de Turgot* (1782). He was drawn from his retirement by Vergennes, who employed him in preparing, along with the English commissioner Dr James Hutton, the treaty for the recognition of the independence of the United States (1782), and a treaty of commerce with Great Britain (1786). Under Calonne he was admitted to the Council of State, and appointed commissary-general of commerce. During the Revolution period he advocated reform and constitutional monarchy as against the views of the extreme republicans, and was therefore destined for vengeance when the republicans triumphed. After the 10th August 1792 he was concealed for some weeks in the observatory of the Mazarin College, from which he contrived to escape to the country. During the time that elapsed before he was discovered and arrested he wrote his *Philosophie de l'univers*. Imprisoned in La Force, he was one of those who had the good fortune to escape the guillotine till the death of Robespierre set them free. As a member of the Council of Five Hundred, Dupont carried out his policy of resistance to the Jacobins, and made himself prominent as a member of the reactionary party. After the republican triumph on the 18th Fructidor (4th September) 1797 his house was sacked by the mob, and he himself only escaped transportation to Cayenne through the influence of M. J. Chénier. In 1799 he found it advisable for his comfort, if not for his safety, to emigrate with his family to the United States. On his return to France in 1802 he declined to accept any office under Napoleon, and devoted himself almost exclusively to literary pursuits. The consideration accorded to him in the United States was shown by his being employed to arrange the treaty of 1803, by which Louisiana was sold to the Union, and by his being requested by Jefferson to prepare a scheme of national education, which was published in 1812 under the title *Sur l'éducation nationale dans les États Unis d'Amérique*. Though the scheme was not carried out in the United States, several of its features have been adopted in the existing French code. On the downfall of Napoleon in

1814 Dupont became secretary to the Provisional Government, and on the restoration he was made a councillor of state. The return of the emperor in 1815 determined him to quit France, and he spent the close of his life with his two sons, who had established a powder manufactory in the state of Delaware. He died near Wilmington, Delaware, on the 6th August 1817.

Dupont's most important works, besides those mentioned above, were his *De l'origine et des progrès d'une science nouvelle* (London and Paris, 1767), *Physiocratie, ou constitution naturelle du gouvernement le plus avantageux au genre humain* (Paris, 1768), and his *Observations sur les effets de la liberté du commerce des grains* (1760). Dupont was a member of the Institute of France, to which he contributed many papers.

DUPUIS, CHARLES FRANÇOIS (1742–1809), an eminent French scientific writer, was born of poor parents at Tryé-Château, between Gisors and Chaumont, October 26, 1742. His father, who was a teacher, instructed him in mathematics and land-surveying. While he was engaged in measuring a tower by the geometric method the Duc de la Rochefoucault met him, and, being struck with his intelligence, gave him a bursary in the college of Harcourt. Dupuis made such rapid progress in his studies that, at the age of twenty-four, he was appointed professor of rhetoric at the college of Lisieux, where he had previously passed as a licentiate of theology. In his hours of leisure he applied himself to the study of the law, and in 1770 was admitted an advocate before Parliament. Two university discourses which he delivered, one on occasion of the distribution of prizes, and the other on the death of the empress Maria Theresa, having been printed, were admired on account of their elegant Latinity, and laid the foundation of the author's fame as a writer. His chief attention, however, was devoted to mathematics, the object of his early studies; and for some years he attended the astronomical lectures of Lalande, with whom he formed an intimate friendship. In 1778 he constructed a telegraph on the principle suggested by Amontons, and employed it in keeping up a correspondence with his friend M. Fortin in the neighbouring village of Bagnaux, until the Revolution rendered it necessary that he should destroy his machine to avoid suspicion.

Much about the same time, Dupuis formed his ingenious theory with respect to the origin of the Greek months. In the course of his investigations upon this subject, he composed a long memoir on the constellations, in which he endeavoured to account for the want of any resemblance between the groups of stars in the heavens and the names by which they are known, by supposing that the zodiac was, for the people who invented it, a sort of calendar at once astronomical and rural, and that the figures chosen for the constellations were such as would naturally suggest the agricultural operations of the season. It seemed only necessary, therefore, to discover the clime and the period in which the constellation of *Capricorn* must have arisen with the sun on the day of the summer solstice, and the vernal equinox must have occurred under *Libra*. It appeared to Dupuis that this clime was Upper Egypt, and that the perfect correspondence between the signs and their significations had existed in that country at a period of between fifteen and sixteen thousand years before the present time, that it had existed only there, and that this harmony had been disturbed by the effect of the precession of the equinoxes. He therefore ascribed the invention of the signs of the zodiac to the people who then inhabited Upper Egypt or Ethiopia. This was the basis on which Dupuis established his mythological system, and endeavoured to explain the subject of fabulous history, and the whole system of the theogony and theology of the ancients.

Persuaded of the importance of his discoveries, which, however, were by no means entirely original, Dupuis

published several detached parts of his system in the *Journal des Savants* for the months of June, October, and December 1777, and of February 1781. These he afterwards collected and published, first in Lalande's *Astronomy*, and then in a separate volume in 4to. 1781, under the title of *Mémoire sur l'Origine des Constellations et sur l'Explication de la Table par l'Astronomie*. The theory propounded in this memoir was refuted by Bailly, in the fifth volume of his *History of Astronomy*, but, at the same time, with a just acknowledgment of the erudition and ingenuity exhibited by the author. Condorcet proposed Dupuis to Frederick the Great of Prussia as a fit person to succeed Thiebault in the professorship of literature at Berlin, and Dupuis had accepted the invitation, when the death of the king put an end to the engagement. The chair of humanity in the college of France having at the same time become vacant by the death of Bejot, it was conferred on Dupuis; and in 1788 he became a member of the Academy of Inscriptions. He now resigned his professorship at Lisieux, and was appointed by the administrators of the department of Paris one of the four commissioners of public instruction. At the commencement of the Revolutionary troubles Dupuis sought an asylum at Evreux; and, having been chosen a member of the National Convention by the department of Seine-et-Oise, he distinguished himself by the moderation of his speeches and public conduct. In the third year of the republic he was elected secretary to the Assembly, and in the fourth he was chosen a member of the Council of Five Hundred. After the memorable 18th Brumaire he was elected by the department of Seine-et-Oise a member of the legislative body, of which he became the president. He had been proposed as a candidate for the senate when he resolved to abandon politics, devoting himself during the rest of his life to his favourite studies. He died September 29, 1809.

In 1794 he published the work by which he is best known, entitled *Origine de tous les Cultes, ou la Religion Universelle* (3 vols 4to, with an atlas, or 12 vols 12mo.) Though its circulation was small, it became the subject of much bitter controversy, and the theory it propounded as to the origin of mythology in Upper Egypt led to the expedition organized by Napoleon for the exploration of that country. In 1798 Dupuis published an abridgment of his work in one volume 8vo, which met with no better success than the original. Another abridgment of the same work, executed upon a much more methodical plan, was published by M. de Tracy. The other works of Dupuis consist of two memoirs on the Pelasgi, inserted in the *Memoirs of the Institute*; a memoir "On the Zodiac of Tentyra," published in the *Revue Philosophique* for May 1806; and a *Mémoire Explicatif du Zodiacus Chronologique et Mythologique* published the same year, in one volume 4to. M. Daier, secretary to the third class of the Institute, delivered his eulogy; and an historical account of his life and writings was published by his widow.

DUPUYTREN, GUILLAUME, BARON (1777-1835), one of the most distinguished of French anatomists and surgeons, was born October 6, 1777, at Pierre Buffière, a small town of Limousin. He was sprung from poor parents, and was furnished with the means of receiving an ordinary education at the College de la Marche by some charitable persons to whom he had been introduced. At the newly established Ecole de Médecine, under Fourcroy, he began the study of medicine with great diligence, and was appointed by competition prosecutor of the faculty when only eighteen years of age. His early studies were directed chiefly to morbid anatomy, which he did much to establish on a scientific basis, though many of his theories were unsound. In 1803 he was appointed assistant-surgeon at the Hôtel-Dieu; and he was appointed professor of operative surgery in succession to Sabbatier in 1811. In 1815 he was appointed to the chair of clinical surgery, and three years later he became head surgeon at the Hôtel-Dieu. Many other offices were conferred upon him; he became inspector of the university, a chevalier and afterwards an officer in the Legion of

Honour, chevalier of St Michel, baron, member of the Institute, and first surgeon to the king. Dupuytren's energy and industry were alike remarkable. He visited the Hôtel-Dieu morning and evening, performing at each time several operations, lectured to vast throngs of students, gave advice to his out-door patients, and fulfilled the duties consequent upon one of the largest practices of modern times. By his indefatigable activity he amassed a fortune of £300,000, the bulk of which he bequeathed to his daughter, with the deduction of considerable sums for the endowment of the anatomical chair in the Ecole de Médecine, and the establishment of a benevolent institution for distressed medical men. The most important of Dupuytren's writings is his *Treatise on Artificial Anus*, in which the principles laid down by John Hunter are happily applied. In his operations he was remarkable for the skill and dexterity with which he overcame the numerous difficulties incidental to so extensive a practice as he enjoyed. He had complete control over his feelings, and great readiness of resource. Instead of attempting to introduce new methods of procedure, he commonly limited himself to modifying and adapting to his particular exigencies the established laws of surgery. He was thus led to invent several new surgical instruments. In private life Dupuytren was cold and reserved, and this was perhaps increased by his constant struggle against a consumptive tendency, which ultimately carried him off, 8th February 1835. In November 1833 he had suffered a slight shock of apoplexy, but he continued in practice almost until the day of his death.

DUQUESNE, ABRAHAM, MARQUIS (1610-1688), one of the most distinguished naval officers in the history of France, was born at Dieppe in 1610. Born in a stirring seaport, the son of a distinguished naval officer, he naturally adopted the profession of a sailor. He spent his youth in the merchant service, and obtained his first distinction in naval warfare by the capture of the island of Lerins from the Spaniards in May 1637. About the same time his father was killed in an engagement with the Spaniards, and the news raised his hatred of the national enemy to the pitch of a personal and bitter animosity. For the next five years he sought every opportunity of inflicting defeat and humiliation on the Spanish navy, and he distinguished himself by his bravery in the engagement at Gattari (1638), the expedition to Coruña (1639), and in battles at Tarragona (1641), Barcelona (1643), and the Cape de Gata. The French navy being left unemployed during the minority of Louis XIV., Duquesne obtained leave to offer his services to the king of Sweden, who gave him a commission as vice-admiral in 1643. In this capacity he defeated the Danish fleet near Gottenburg and thus raised the siege of the city. The Danes returned to the struggle with increased forces under the command of King Christern in person, but they were again defeated,—their admiral being killed and his ship taken. Peace having been concluded between Sweden and Denmark in 1645, Duquesne returned to France. The revolt at Bordeaux, supported as it was by material aid from Spain, gave him the opportunity of at once serving his country and gratifying his long cherished hatred of the Spaniards. In 1650 he fitted out at his own expense a squadron with which he blockaded the mouth of the Gironde, and compelled the city to surrender. For this service he was promoted in rank, and received a gift of the castle and isle of Indre, near Nantes. Peace with Spain was concluded in 1659, and for some years afterwards Duquesne was occupied in endeavours to suppress piracy in the Mediterranean. On the revolt of Messina from Holland, he was sent to support the insurgents, and had to encounter the united fleets of Spain and Holland under the command of the celebrated Admiral De Ruyter.

After several battles, in which the advantage was generally on the side of the French, a decisive engagement took place near Catania, on the 20th April 1676, when the Dutch fleet was totally routed and De Ruyter mortally wounded. The greater part of the defeated fleet was afterwards burned in the harbour of Palermo, where it had taken refuge, and the French thus secured the undisputed command of the Mediterranean. For this important service Duquesne received a letter of thanks from Louis XIV., together with the title of marquis and the estate of Bonchet. Owing to his being a Protestant, however, his professional rank was not advanced. His last achievements were the bombardment of Algiers (1682-3), in order to effect the deliverance of the Christian captives and the bombardment of Genoa in 1684. On the revocation of the Edict of Nantes Duquesne lost his commission, but he was specially excepted from banishment. He died at Paris on the 2d February 1688.

DURAN, AUGUSTIN (1789-1862), one of the leaders of the literary movement in Spain during the present century, was born at Madrid, where his father held the post of court physician. He lost his mother in childhood, and, instead of being educated in the capital, was sent to the seminary at Vergara, rather to gain strength and health than such mathematics and Latin as his clerical teachers could supply. Thence he returned a firm believer in ghosts, and erudite in the traditions of Spanish romance. In 1817 he joined the university of Seville for the study of philosophy and law, and in due course was admitted an advocate at Valladolid. From 1821 to 1823 he held a post in the *direccion general de estudios* at Madrid; but in the latter year he was discarded on account of his political opinions, and it was not till 1834 that he received a new appointment as secretary of the board for the censorship of the press, shortly afterwards supplemented by a post in the National Library at Madrid. The revolution of 1840 again led to his dismissal, but he recovered his position in 1843, and in 1854 attained the rank of director of the library. Next year, however, he retired, and the rest of his life was devoted to his literary work. He died in 1862. It was in 1828, shortly after his first discharge from office, that he published his discourse on the influence which modern criticism had exercised on the ancient Spanish theatre (*Discurso sobre el influjo que ha tenido la critica moderna en la decadencia del teatro antiguo*), and, though the work was anonymous, it produced a marvellous effect on the tendencies of the national drama. He next endeavoured to make better known to his fellow-countrymen those half-forgotten treasures of their literature, in the collection of which he had spared neither money nor toil. Five volumes of a *Romancero general* appeared from 1828 to 1832 (republished, with considerable additions and improvements, in 2 vols. 1849-1851), and *Talia española*, or a collection of old Spanish comedies, in 3 vols., in 1834. As an original poet the author is best known by a poem in imitation of the style of the 15th century, entitled *Las tres toronjas del vergel de amor*, or "The Three Citron Trees of the Orchard of Love."

DURANDUS, WILHELMUS (1237-1296), otherwise DURANTIS or DURANTI, was born at Puissemon, sometimes written Puissemon, a small town in the diocese of Beziers, in Languedoc, whence he is sometimes described as a native of Provence. He studied law under Bernardus of Parma, in the university of Bologna, where he was promoted to the degree of doctor. He shortly afterwards migrated to the university of Modena, where he became so famous by his lectures on the canon law that he attracted the notice of Pope Clement IV., who appointed him auditor of the palace, and subsequently subdeacon and chaplain. In 1274 he accompanied Pope Gregory X. as his secretary to the Council of Lyons, which is reckoned as the fourteenth general council,

and under the pontificates of several subsequent popes filled many highly responsible offices. He was appointed in 1277 spiritual and temporal legate of the patrimony of St Peter under Pope Nicholas III., and in 1278 took possession, in the name of the same Pope, of the provinces of Bologna and Romagna. In 1281 Pope Martin IV. named him vicar spiritual, and in 1283 governor of the temporalities of the two provinces, in which office he had the direction of the war against the rebellious province of Romagna. The town of Castrum Riparum Urbanatum having been burnt down during the war, he rebuilt it, and renamed it Castrum Durantis. Pope Urban VIII. subsequently gave to this town the name of Urbania, which it bears in the present day. Pope Honorius IV. retained Durandus in the same offices until the end of 1286, when his election to the bishopric of Meude, in Languedoc, was the occasion of his retiring for a short time from the conduct of civil affairs. Durandus, however, appears to have remained in Italy, and to have revised at this time several of his works. He refused in 1295 the archbishopric of Ravenna, which was offered to him by Pope Boniface VIII., and accepted in preference the more arduous office of governor of the province of Romagna and of the march of Ancona. The party of the Ghibellines, however, carried on hostilities against the Holy See with so much vigour that he found his strength unequal to the exigencies of government; and, having resigned his office, he retired to Rome, where he died on 1st November 1296.

Durandus was the author of several very learned works. The most famous of them is his *Speculum Judiciale*. This work is entitled in the printed copies, the earliest of which was published at Rome in folio in 1474, as *Speculum Juris*, but all the MSS. have the title of *Speculum Judiciale*; and Durandus himself, in his epistle dedicatory to Cardinal Ottobonus Fiesco, afterwards Pope Adrian V., describes it under this latter title. It is a practical treatise on civil and canon law, and it earned for its author, when young, the surname of the Father of Practice. Durandus is said to have completed it in 1271, at the age of thirty-four, and he revised it some time between 1287 and 1291. It has since his death acquired much celebrity as one of the best sources of the dogmatic history of law, and the canonists are accustomed to cite Durandus under the bye-name of "the Speculator." The original work has been enriched by additions from the pen of John Andrew in 1346, and by further additions from the pen of Baldus. An alphabetic table of its contents (*Inventorium*) was drawn up by Cardinal Berauger in 1306, and the *Speculum* passed through thirty-eight editions between 1474 and 1678. The next important work of Durandus is his *Repertorium Aureum* or *Breviarium*, which is dedicated to Cardinal Matthæus, Durandus himself in his preface designates this work by the name of *Breviarium*, but it is described by him in the Preface to the *Speculum* by the title of *Repertorium Aureum*, under which title it is more generally known. It is supposed to have been composed by Durandus in the interval between the first completion and the revision of the *Speculum*. His *Commentarius in Concilium Lugdunense* is a work of much interest, as Durandus himself drew up the Decretals, which after his death were inserted in the *Sextus*. Durandus also wrote a commentary on the decretals of Pope Nicholas III., which is only known to us from the epitaph on his tomb, as preserved by Sarti, and which enumerates all his chief writings, amongst which may be mentioned his *Speculum Legatorum*, inserted in the *Speculum Judiciale*, his *Rationale Divinorum Officiorum*, which has passed through many editions, the earliest of which was printed at Mayence in 1459, and a copy of which is stated by the Abbé Pascal to have been sold for 2700 francs. A manuscript of his *Pontificale Patrum*, being a treatise on the duties of bishops, is preserved in the National Library of Paris. Durandus the Speculator is sometimes confounded with Durandus of Santo Porciano, bishop of Meaux, who died in 1332, and was the author of two treatises, *De Jurisdictione* and *De Legebus*, and with Wilhelmus Durandus, his own nephew, who was the author of a work entitled *De modo celebrandi Consilii*, and who died in Cyprus in 1328.

DURANGO, a town of Spain, in the province of Biscay 16 miles south-east of Bilbao, at the confluence of the Durango and the Mañaria. As a military position of some importance it is often mentioned in history, its church of San Pedro de Tavira is one of the earliest in the Biscayan district, and that of Santa Ana has some interesting altars constructed by Ventura Rodriguez in 1774. The inhabit-

ants, who number about 2600, are partly engaged in the manufacture of iron and steel, and carry on a trade with Hamburg in chestnuts. The foundation of the town is ascribed to the early kings of Navarre, and in 1153 it obtained the rank of a countship. The decree by which Don Carlos in 1839 ordered all foreigners taken in arms against him to be shot was issued from Durango.

DURANGO, sometimes called CIUDAD DE VICTORIA, or GUADIANA, a city of Mexico, the capital of the state of Durango, lies near the foot of the south-eastern slope of the Sierra Madre, at a height of 6847 feet above the sea, in 24° 25' N. lat. and 105° 55' W. long. It is the centre of a Roman Catholic bishopric, and possesses a cathedral, ten parish churches, a hospital, Government-buildings, a penitentiary, a state prison, a bull-ring, and a large cock-pit. Formerly the seat of a Jesuit college, it still maintains an episcopal seminary, and an institute with literary, legal, and scientific departments. It is well supplied with water by thermal and other springs, which not only satisfy the demands of nine public baths, but also fill considerable channels along the streets. Trade is carried on with the northern and north-western states; and, besides a mint, a gold refinery, and other offices connected with the mining operations, there are glass works, printing-presses, and factories for cotton and woollen goods, leather, and tobacco. Durango was founded in 1559 or 1560 by Alonso Pacheco, an officer of the Viceroy Velasco, as a military post for the control of the Chichimecas. It was soon after made an episcopal see, but did not attain any great importance till the discovery of the rich deposits of Guarisamey; and most of its public buildings were erected at the expense of Zambrano, the owner of the mines. In 1783 it had no more than 8000 inhabitants; about 1850 they were estimated at 30,000 or 40,000; in 1868 they were reduced to 12,449.

DURANTE, FRANCESCO, a celebrated Italian composer, and one of the founders of the so-called Neapolitan school of music, was born at Frattamaggiore, in the kingdom of Naples, and not, as has been erroneously stated, in the city of that name. The date of his birth is generally given nine years too late. In reality he was born on March 15, 1684. At an early age he entered the Conservatorio dei poveri di Gesù Cristo, at Naples, where he received lessons from Gaetano Greco; but soon he attracted the attention of the celebrated Alessandro Scarlatti, at that time the head and ornament of another great music school of Naples, the Conservatory of St Onofrio. Under him Durante studied for a considerable time, and left him only to go to Rome, where, during further five years, he completed his vocal studies under Pitoni. On his return to Naples he obtained the position of chapel-master at the school of St Onofrio, which he occupied till 1742, when he succeeded Porpora as head of the Conservatorio Sante Maria di Loretto, also at Naples. This post he held for thirteen years, till his death in 1755. His fame as a teacher was all but unrivalled, and the most celebrated masters of the earlier school of Italian opera are amongst his pupils. Only Jomelli, Paisiello, Pergolesi, Piccini, and Vinci may be mentioned here. Under him the Neapolitan school of music reached its climax of celebrity, and it was in this school that the great traditions of Italian vocal art were established, the last remnants of which are rapidly disappearing from the modern stage. As a composer Durante adhered to the severe style of the early Italian masters. The structure of his choral pieces is surpassed by Handel alone amongst his contemporaries. His instrumentation also shows many new and beautiful effects. A complete collection of Durante's works, consisting all but exclusively of sacred compositions, was presented by Selvaggi, a Neapolitan lover of art, to the Paris library. A catalogue of it may be found in Fétis's *Biographie Universelle*. The

imperial library of Vienna also preserves a valuable collection of Durante's manuscripts. Two requiems, several masses (one of which, a most original work, is the Pastoral Mass for four voices), and the Lamentations of the Prophet Jeremiah are amongst his most important settings.

DURÃO, JOSE DE SANTA RITA, a Brazilian poet, was born at Marianna, in the province of Minas Geraes, in 1737, and died at Lisbon in 1784. He studied at Coimbra, in Portugal, graduated as a doctor of divinity, became a member of the Augustinian order of friars, and obtained a great reputation as a preacher. Having irritated the minister Pombal by his defence of the Jesuits, he retired from Portugal; and, after being imprisoned in Spain as a spy, found his way to Italy, where he became acquainted with Alfieri, Pindemonte, Casti, and other literary men of the time. On his return to Portugal he delivered the opening address at the university of Coimbra for the year 1778; but soon after retired to the cloisters of a Gratian convent. At the time of his death he taught in the little college belonging to that order in Lisbon. His principal poem, entitled *Caramuru, poema epico do descobrimento da Bahia*, appeared at Lisbon in 1781, but proved at first a total failure. Its value has gradually been recognized, and it now ranks as one of the best poems in Brazilian literature—remarkable especially for its fine descriptions of scenery and native life in South America. The historic institute of Rio de Janeiro offered a prize to the author of the best essay on the legend of Caramuru; and the successful competitor published a new edition of Durão's poem. There are two French translations, one of which appeared in 1829 in 3 vols. 8vo.

See Adolfo de Varnhagen, *Epicas Brasileiras*, 1845, Pereira da Silva, *Os Varões illustres do Brasil*, 1858, Wolf, *Le Brésil littéraire*, Berlin, 1863.

DURAZZO, the ancient *Dyrrachium*, or *Epidamnus*, in Turkish Dratsh, and in Slavonian Durtz, a seaport town of European Turkey, in Albania, about fifty miles south of Scutari, on the eastern shore of the Adriatic. It is the seat of a Roman Catholic bishop and a Greek archbishop, but in every respect has greatly declined from its former prosperity. The walls are dilapidated; plantain trees are growing on the gigantic ruins of its old Byzantine citadel; and its harbour, once equally commodious and safe, is gradually becoming silted up. The only features worthy of notice are the quay, with its rows of cannon, and the bridge, 750 feet long, which leads across the marshy stretch along the coast. Such trade as it still possesses is mainly carried on with Trieste, and consists in the export of grain, skins, wool, wood, and leeches. The population is estimated at 9000.

DURBAN, or more correctly D'URBAN, a town of South Africa, in Natal, in the county of Durban, situated on a sandflat about a mile to the north of the bay of Port Natal, in 29° 52' S. lat. and 31° 2' E. long. It is well laid out with wide tree-shaded streets, carries on a considerable export and import trade, and possesses an Episcopalian church, two Wesleyan chapels (one for natives and the other for Europeans), a Government school, a prison, a custom-house, a literary institution, and an agricultural and horticultural society. Durban was founded in 1834 as the capital of the republican colony of Victoria, and its name was bestowed in honour of Sir Benjamin D'Urban, the governor of the Cape. The population, mostly English, was in 1866, 4991.

DÜREN, a town of Prussia, at the head of a circle in the province of the Rhine, on the right bank of the Roer, at a railway junction eighteen miles east of Aix-la-Chapelle. Besides two Roman Catholic and two Protestant churches, it possesses three nunneries, a gymnasium, a mining school, and a blind asylum—the Elizabeth Institution—which was

founded in 1845 and in 1863 was made a provincial establishment. Woollen goods, paper, and needles are manufactured on an extensive scale; and flax-spinning, felt-weaving, wire-weaving, rail-casting, and zinc-rolling are also carried on.

Düren is probably to be identified with the *Marcodurum* of the *Ubi*, where they were defeated by *Civitas* in 69 A.D. It received from Charlemagne the rank of an imperial city, and its claims were confirmed by Rupert in 1407. Pawned by Frederick II to Count William of Juliers as security for the payment of a debt, it was ultimately incorporated with the duchy of Juliers. Its name frequently occurs in the history of the Palatinate. Population in 1875, 14,542.

DÜRER, ALBRECHT (1471–1528), was born at Nuremberg on the 21st of May 1471, he was therefore six years older than Titian and twelve years older than Raphael. In the history of art, Albert Durer has a name equal to that of the greatest of the Italians. North of the Alps, his only peer was Holbein. But Holbein was not born till 1497, and lived after 1525 principally in England; hence in youth he came within the influence of the already matured arts of Italy, and in manhood his best powers were concentrated on the painting of portraits in a foreign country. Durer lived a German among Germans, and is the true representative artist of that nation. All the qualities of his art—its combination of the wild and rugged with the homely and tender, its meditative depth, its enigmatic gloom, its sincerity and energy, its iron diligence and discipline—all these are qualities of the German spirit. And the hour at which Durer arose to interpret that spirit in art was the most pregnant and critical in the whole history of his race. It was the hour of the Renaissance, of the transition between the Middle Ages and our own. The awakening of Germany at the Renaissance was not, like the other awakening of Italy at the same time, a movement merely intellectual. It was, indeed, from Italy that the races of the North caught the impulse of intellectual freedom, the spirit of science and curiosity, the longing retrospect towards the classic past, but joined with these, in Germany, was a moral impulse which was her own, a craving after truth and right, a rebellion against tyranny and corruption, an assertion of spiritual independence—the Renaissance was big in the North, as it was not in the South, with a Reformation to come. The art of printing was invented at the right time to help and hasten the new movement of men's minds. Nor was it by the diffusion of written ideas only that the new art supplied the means of popular enlightenment. Along with word-printing, or indeed in advance of it, there had come into use another kind of printing, picture-printing, or what is commonly called engraving. Just as books, or word-printing, were the means of multiplying, cheapening, and disseminating ideas, so engravings, or picture-printing, were the means of multiplying, cheapening, and disseminating images which gave vividness to the ideas, or served, for those ignorant of letters, in their stead. Technically, the art of engraving was a development of the art of the goldsmith or metal-chaser. Between the art of the goldsmith and the art of the painter there had always been a close alliance, both being habitually exercised by persons of the same family, and sometimes by one and the same person; so that there was no lack of hands ready trained, so to speak, for the new art which was a combination of the other two, and required of the man who practised it that he should design like a painter and cut metal like a goldsmith. The engraver on metal habitually cut his own designs; whereas designs intended to be cut on wood were usually handed over to a class of workmen—*Formschneider*—especially devoted to that industry. Both kinds of engraving soon came to be in great demand. Independently of the illustration of written or printed books, separate engravings, or sets of engravings, were produced, and found

a ready sale at all the markets, fairs, and church-festivals of the land. Subjects of popular devotion predominated. Figures of the Virgin and child, of the apostles, the evangelists, the fathers of the church, the saints and martyrs, with illustration of sacred history and the Apocalypse, were supplied in endless repetition to satisfy the cravings of a pious and simple-minded people. But to these were quickly added subjects of allegory, subjects of classical learning—confused mythologies of Hercules, Satyr, and Triton—subjects of witchcraft and superstition, subjects of daily life, scenes of the parlour and the cloister, of the shop, the field, the market, and the camp; and lastly portraits of famous men, with scenes of court life and princely pageant and ceremony. The emperor Maximilian himself, chivalrous, adventurous, ostentatious, on fire with a hundred ambitions, and above all with the desire of popular fame, gave continual employment to the craftsmen of Augsburg and Nuremberg in designing and engraving processional and historical representations, which were destined to commemorate him to all time in his double character of imperial lawgiver and hero of romance. So the new art became the mirror, for all men to read, of all the life and thoughts of the age.

The genius of Albert Durer cannot be rightly estimated without taking into account the position which the art of engraving thus held in the culture of his time. He was, indeed, first of all a painter; and though in his methods he was too scrupulous and laborious to produce many great works, and though one of his greatest, the Assumption of the Virgin, has been destroyed by fire, and another, the Feast of Rose-Garlands, has suffered irreparably between injury and repair, yet the paintings which remain by his hand are sufficient to place him among the great masters of the world. He has every gift in art except the Greek and the Italian gift of beauty or ideal grace. In religious painting, he has profound earnestness and humanity, and an inexhaustible dramatic invention; and the accessory landscape and scenery of his compositions are more richly conceived and better studied than by any painter before him. In portrait, he is equally master of the soul and body, rendering every detail of the human superficies with a microscopic fidelity, which nevertheless does not encumber or overlay the essential and inner character of the person represented. Still more if we judge him by his drawings and studies, of which a vast number are preserved in private as well as public collections, shall we realize his power in grasping and delineating natural fact and character, the combined gravity and minuteness of his style, the penetration of his eye, and the almost superhuman patience and accuracy of his line in drawing, whether from persons, animals, plants, or landscape, whether with pen, pencil, charcoal, or (which was his favourite method) in colour with the point of the brush. But neither his paintings nor his drawings could by themselves have won for him the immense popular fame and authority which have been his from his own time to ours; that fame and that authority are due to his pre-eminence in the most popular and democratic of the arts, that of which the works are accessible to the largest number, the art of engraving. In an age which drew a large part of its intellectual nourishment from engravings, Durer furnished the most masterly examples both of the refined and elaborate art of the metal engraver, as well as the most striking inventions for the robust and simple art of the wood engraver.

The town of Nuremberg in Franconia, in the ago of Durer, was a home most favourable to the growth and exercise of his powers. Of the free imperial cities of central Germany, none had a greater historic fame, none a more settled and patriotic government, none was more the favourite of the emperors, none was the seat of a more active

and flourishing commerce. Nuremberg was the great mart for the merchandise that came to central Europe from the East through Venice and over the passes of the Tyrol. She held not only a close commercial intercourse, but also a close intellectual intercourse, with Italy. Without being so forward as the neighbour city of Augsburg to embrace the architectural fashions of the Italian Renaissance,—nay, continuing to be profoundly imbued with the old German burgher spirit, and to wear, with an evidence which is almost unimpaired to this day, the old German civic aspect,—she had imported, before the close of the 15th century, much of the new learning of Italy, and numbered among her citizens a Willibald Pirckheimer, a Sebald Schreyer, a Hartmann Schedel, and others fit to hold a place in the first rank of European humanists. The life into which Albert Dürer was born was a grave, a devout, a law-loving, and a lettered life, in the midst of a community devoted to honourable commerce and honourable civic activities, proud of its past, proud of its wealth, proud of its liberties, proud of its arts and ingenuities, and abounding in aspects of a quaint and picturesque dignity. His family was not of Nuremberg descent, but came from the village of Eyta in Hungary. The name, however, is German, and the family bearing—an open door—points to an original form of *Thürer*, meaning a maker of doors, or carpenter. Albrecht Dürer the elder was a goldsmith by trade, and settled soon after the middle of the 15th century in Nuremberg. He served as assistant under a master goldsmith of the city, Hieronymus Holper, and presently married his master's daughter, Barbara. This was in 1468, the bridegroom being forty and the bride fifteen years of age. They had eighteen children, of whom Albert was the second. The elder Dürer was an esteemed craftsman and citizen, sometimes, it seems, straitened by the claims of his immense family, but living in virtue and honour to the end of his days. The accounts we have of him proceed from his illustrious son, who always speaks with the tenderest reverence and affection of both his parents, and has left a touching narrative of the deathbed of each. He painted the portrait of his father twice, once about 1490, the second time in 1497. The former of these two pieces is in the Uffizj at Florence, the latter, well known by Hollar's engraving, is in the possession of the duke of Northumberland. A third "Portrait of his Father" by Dürer, in the gallery at Frankfort, is probably so called in error. The young Albert was his father's favourite son. "My father," these are his own words, "took special delight in me. Seeing that I was industrious in working and learning, he put me to school; and when I had learned to read and write, he took me home from school and taught me the goldsmith's trade." By-and-by the boy found himself drawn by preference from goldsmith's work to painting; and after some hesitation, his father at first opposing his wishes on the ground of the time already spent in learning the former trade, he was at the age of fifteen and a half apprenticed for three years to the principal painter of the town, Michael Wöhlgemuth. Wöhlgemuth furnishes a complete type of the German painter of that age. At the head of a large shop with numerous assistants, his business was to turn out, generally for a small price, devotional pieces commissioned by mercantile corporations or private persons to decorate their chapels in the churches,—the preference being usually for scenes of our Lord's Passion, or for tortures and martyrdoms of the saints. In work of this class, the painters of upper Germany before the Renaissance show considerable technical knowledge, and a love of rich and quaint costumes and of landscape, but in the human part of their representations often a grim and debased exaggeration, transgressing all bounds in the grotesqueness of undesigned caricature.

Wöhlgemuth and his assistants also produced woodcuts for book illustration, and probably—though this is a vexed question—engravings on copper. In this school Dürer learnt much, by his own account, but suffered also not a little from the roughness of his companions. At the end of his term under Wöhlgemuth, he entered upon the usual course of travels—the *Wanderjahre*—of a German youth. The direction of these travels we cannot retrace with certainty. It had been at one time his father's intention to apprentice him to Martin Schongauer, of Colmar in Alsace, incomparably the most refined German painter and engraver of his time. To Colmar, among other places, Albert Dürer went in the course of his travels, but Schongauer had already died there in 1488. We also hear of him at Strassburg. It is a moot point among biographers whether towards the end of his *Wanderjahre*—about the year 1494—the young Dürer did or did not cross the Alps to Venice. On the one hand it is argued that he did, first, because, on the occasion of an undoubted visit to Venice in 1506, he speaks of admiring no longer that which he had vastly admired "eleven years before;" secondly, because several careful drawings by his hand from the engravings of Mantegna and other Italian masters, bearing the date 1494, show that in this year he was making a special study of Italian art; and thirdly, because he has left a number of coloured drawings of the scenery of Tyrol, such as he would have to traverse on the road between Bavaria and Venice, and these show a technical finish and minuteness of execution, characteristic of his studies at this early period but not later. Those who do not believe in this early visit to Venice reply, first, that the allusion interpreted as above in Dürer's correspondence is too vague and uncertain, and that what Dürer, in 1506, had really "admired eleven years ago" was probably not the work of Venetians seen at Venice, but of a Venetian artist known as Jacopo de' Barbari, or Jacob Walch, who resided about that time in Nuremberg, and who, we know, had a very considerable influence on the art of Dürer; secondly, that the prints of Mantegna and other Italians, undoubtedly copied by Dürer in 1494, may very well have been brought to Germany with other wares on sale from Venice, or have been shown him by the same Jacopo de' Barbari; and thirdly, that other landscapes, bearing the date of 1506 or later dates, do in fact show the same technical characteristics as those which are assigned, by the other side in the argument, to 1494. The question will probably remain open to the end. With reference, however, to the third head of the argument, the character of Dürer's early landscape work, it has not been sufficiently observed that his ideal of scenery shows itself fully formed and developed by the time of the publication of his Apocalypse woodcuts and his earliest engravings on copper, that is, about the year 1497; that this ideal background, of a lake with castled and wooded headlands sloping down from either side, and sloops afloat in the distance, is taken not from the neighbourhood of Nuremberg but from the northern borders of Tyrol—it is the scenery, not of the banks of the Pegnitz nor even the Danube, but rather of the Wurmsee or the Tegernsee; that to the Alps and lakes, therefore, of the Northern Tyrol, whether on his way to Venice or otherwise, Dürer must certainly have come during these travels of his youth.

At the end of May 1494, being twenty-three years old, Albert Dürer returned, at his father's summons, to his native Nuremberg, and within two months was married to Agnes, the daughter of a well-to-do merchant of the town named Hans Frey. It is probable that the marriage had been arranged between Hans Frey and the elder Dürer while Albert was on his travels; and possible that a portrait of the young painter very richly habited, executed by himself

in the previous year 1493, and showing him in the first bloom of that admirable manly beauty for which he was afterwards renowned, may have been destined to recommend him to the good graces of the lady. Their marriage was childless. Agnes survived her husband. The petulance of an old friend of her husband's has unjustly blackened her reputation. Her name has for centuries been used to point a moral, and among the unworthy mates of great men the wife of Durer was as notorious as the wife of Socrates. The origin of this tradition must be sought in a letter written a few years after Durer's death by his close friend and life-long companion, Willibald Pirckheimer, in which Pirckheimer accuses Agnes of having plagued her husband to death with her parsimonious ways, of having made him over-work himself for money's sake, of having given his latter days no peace. But a closer study of facts and documents shows that there is not a jot of evidence to support these splenetic charges. Pirckheimer, when he made them, was old, broken with gout, and disgusted with the world, and the immediate occasion of his outbreak was a fit of peevishness against the widow because she had not let him have a pair of antlers—a household ornament much prized in those days—to which he fancied himself entitled out of the property left by Durer. On the other hand, there is abundant evidence of the close confidence and companionship that subsisted between Durer and his wife; she accompanied him on his journey to the Low Countries in 1521; after his death she behaved with peculiar generosity to his brothers; it is perfectly probable that Durer had in her a kind and beloved as well as a careful partner, the old legend of his sufferings at her hands must be regarded as completely discredited. So far from being forced to toil for money to the end, he died well off, though he had in his latter years occupied himself more and more with unremunerative pursuits—with the theoretical studies of Perspective, Geometry, Fortification, Proportion, for which he shared the passion of Leonardo, and on which, like Leonardo, he has left written treatises.

For more than eleven years after his marriage, Durer lived at Nuremberg the settled and industrious life of his profession. Within this period his masterly powers unfolded and matured themselves. Two important devotional pictures are attributed to his early practice; one a large triptych painted in tempera on linen, now in the gallery at Dresden, the other also an altar-piece with wings, now in the summer palace of the archbishop of Vienna at Ober St Veit, both probably painted for the Elector Frederick of Saxony. These pictures have been executed, like those of Wohlgemuth, hastily, and with the help of pupils. (Of painters trained in the school of Durer, we know the names and characters of Schaufelein, Sprungmiller, Hans Baldung Grien, and Hans of Culmbach). A finer, and somewhat later, example of the master's work in this class is the altar-piece painted for the family of Baumgartner, having a Birth of Christ in the centre and the figure of a knight on either side, this is now at Munich. The best of Durer's energies, both of mind and hand, must have been given in these days to the preparation of his sixteen great woodcut designs for the Apocalypse. The first edition illustrated with this series appeared in 1498. The Northern mind had long dwelt with eagerness on these mysteries of things to come, and among the earliest block-books printed in Germany is an edition of the Apocalypse with rude figures. But Durer not only transcends all efforts made before him in the representation of these strange promises, terrors, and transformations, these thaumaturgic visions of doom and redemption; the passionate energy and undismayed simplicity of his imagination enable him, in this order of creations, to touch the highest point of human achievement. The four angels keeping back the winds that they blow not, the four riders, the loosing of the

angels of the Euphrates to slay the third part of men; these and others are conceptions of such force, such grave or tempestuous grandeur in the midst of grotesqueness, as the art of no other age or hand has produced. At the same time, Durer was practising himself diligently in the laborious art of copper engraving. In the years immediately about or preceding 1500, he produced a number of plates of which the subjects are generally fanciful and allegorical, and the execution is more or less tentative and uncertain. Of several of these, other versions exist by contemporary masters, and it is disputed in most of such cases whether Durer's version is the original, or whether, being at that time young and comparatively unknown, he did not rather begin by copying the work of older men; in which case, the originals of such engravings would have to be sought in versions bearing other signatures than Durer's. One signature of frequent occurrence on German engravings of this time, and among them, on several subjects which are also repeated by Durer's hand, is the letter W. As to the identity of this W, criticism is much divided. He has been generally identified with one Wenzel of Olmutz, whom we know to have engraved copies after Martin Schongauer and other masters. Others, again, attribute some at least of the prints signed W to Durer's teacher Wohlgemuth, and when the same composition is found engraved by each of the two masters, conclude that the younger has copied the work of the elder. Instances are the subjects of the Four Naked Women with Death and the Fiend; the Old Man's Dream of Love; the Virgin and Child with the Ape, &c. The question is difficult to decide. It seems certain that the work of several different hands is signed with this same initial W; and we are of those who hold that, of the engravers so signing, one, whether Wohlgemuth or not, is a very accomplished master, whose work Durer, until near the age of thirty, was in the habit of occasionally copying. From another master, again, whose name we have already mentioned, the half Venetian half German Jacopo de' Barbari, Durer learned much. The Italians had already begun to work out a science of the human structure and of ideal proportions; and from Jacopo de' Barbari, as Durer himself tells us, he received in youth the first hints of this science; which he subsequently investigated for himself with his usual persistent industry. These early notions received from Jacopo de' Barbari led to one immediate result of value, the famous engraving of Adam and Eve published in 1501. The figures here, as we can see by many preparatory sketches, are planned on geometrical principles, not drawn—as was the common German custom, and Durer's own in a large majority of his work—direct from the model, with all the erudities of the original faithfully delineated. The background of foliage and animals is a miracle of rich invention and faithful and brilliant execution; the full powers of Durer as an engraver on copper are here for the first time asserted. In another elaborate engraving which probably soon followed this—the Great Fortune or Nemesis—the opposite principle is observed; above a mountain valley, of which every detail is rendered in bird's eye view with amazing completeness, an allegorical figure of a woman rides upright upon the clouds, bearing a cup in one hand and a bridle in the other, in her countenance and proportions there is nothing ideal, there is the most literal and graceless commonness. In his own journals Durer calls this plate *Nemesis*; it has been conjectured that the piece was composed in allusion to the unfortunate expedition sent by the emperor Maximilian to Switzerland, in which a number of Nuremberg citizens took part, with Pirckheimer at their head. In the meantime Durer had been variously exercising his inexhaustible power of dramatic invention on the subjects of Christian story. He had completed the set of drawings of the Passion

of Christ, in white on a green ground, which is known as the Green Passion, and forms one of the treasures of the Albertina at Vienna. He had followed up his great woodcut series of the Apocalypse with preparations for other series on a similar scale, and had finished seven out of twelve subjects for the set known as the Great Passion, and sixteen out of twenty for the Life of the Virgin, when his work was interrupted by a journey which is one of the principal episodes in his life. In the autumn of the year 1505 he went to Venice, and stayed there until the autumn of the following year.

The occasion of this journey has been erroneously stated by Vasari. Dürer's engravings, having by this time attained a great popularity both north and south of the Alps, had begun to be copied by various hands, and among others by the celebrated Marcantonio of Bologna, then in his youth. According to Vasari, Marcantonio, in copying Dürer's series of the Little Passion on Wood, had imitated the original monogram, and Dürer, indignant at this fraud, set out for Italy in order to protect his rights, and having lodged a complaint against Marcantonio before the signory of Venice, carried his point so far that Marcantonio was forbidden in future to add the monogram of Dürer to copies taken after his works. This account will not bear examination. Chronological and other proofs show that if such a suit was fought at all, it must have been in connection with another set of Dürer's woodcuts, the first sixteen of the Great Passion on Wood. Dürer himself, a number of whose familiar letters written from Venice to his friend Pirkheimer at Nuremberg are preserved, makes no mention of anything of the kind. Nevertheless something of the kind may probably have been among the causes which determined his journey. Other causes, of which we have explicit record, were an outbreak of sickness at Nuremberg; Dürer's desire, which in fact was realized, of finding a good market for the proceeds of his art; and the prospect, also realized, of a commission for an important picture from the German community settled at Venice, who had lately caused an exchange and warehouse—the *Fondaco de' Tedeschi*—to be built on the Grand Canal, and who were now desirous to dedicate a picture in the church of St Bartholomew. The picture painted by Dürer on this commission was the Adoration of the Virgin, better known as the Feast of Rose-Garlands; it was subsequently acquired by the emperor Rudolf II, and carried as a thing beyond price upon men's shoulders to Vienna; it now exists in a greatly injured state in the monastery of Strachow, near Prague. It is one of Dürer's best conceived and most multitudinous compositions, and one in which he aims at rivalling the richness and playfulness of Italian art. Other pictures probably painted by him at Venice are Christ disputing with the Doctors, now in the Palazzo Barberini at Rome, Christ Crucified, in the gallery at Dresden, and a Madonna and Child in the possession of Lord Lothian. These works of the German master were not without influence upon the Italian painters resident at Venice, an influence which we can distinctly trace in some of the early works of Titian. Dürer's letters testify to the high position he held at Venice, and speak of the jealousy shown towards him by some of the meaner sort of artists, the friendship and courtesy by the nobler sort, and especially by the noblest of all, the veteran Giovanni Bellini. He talks of the honour and wealth in which he might live if he would consent to abandon home for Italy, of the Northern winter, and how it will make him shiver. Yet he resisted the seductions of the South, and was in Nuremberg again before the close of 1506. First, it seems, he had made an excursion to Bologna, having intended to take Mantua on the way, in order to do homage to the old age of that Italian master, Andrea Mantegna, from whom he had him-

self in youth learnt the most. But the death of Mantegna prevented this purpose.

From the winter of 1506 until the summer of 1520, Dürer was again a settled resident in his native town. During these years his genius and his fortunes were at their height. Except the dazzling existence of Raphael at Rome, the annals of art present the spectacle of no more honourable or more enviable career. Dürer's fame had spread all over Europe. From Antwerp to Rome his greatness was acknowledged, and artists of less invention, among them some of the foremost on both sides of the Alps, were not ashamed to borrow from his work this or that striking combination or expressive type. He was on terms of friendship or friendly communication with all the first masters of the age, and Raphael held himself honoured in exchanging drawings with Dürer. In his own country, all orders of men, from the emperor Maximilian down, delighted to honour him; he was the familiar companion of chosen spirits among statesmen, humanists, and reformers, and had the power to bind to himself with the links of a more than brotherly friendship the leading citizen of the leading city of Germany, Willibald Pirckheimer. His temper and his life were singularly free from all that was jarring, jealous, or fretful. The burgher life of even this, the noblest German city, seems narrow, quaint, and harsh beside the grace and opulence and poetry of Italian life in the same and the preceding generation, but among its native surroundings, the career of Dürer stands out with an aspect of ideal elevation and decorum which is its own. He is even distinguished from his fellow citizens by the stately beauty of his aspect and the rich elegance of his attire. Every reader will be familiar with the portrait in which he has represented himself at this middle period of life—the nobly formed oval countenance, with the short beard, and the long carefully divided locks curled and flowing over either shoulder, the upright brow, the steadfast penetrating gaze of the large perfectly cut eyes, the long nose somewhat aquiline, and full perfectly cloven mouth, the strong delicate fingers playing with the rich fur lapet of his cloak.

These years of Dürer's life can best be divided according to the several classes of work with which, during their succession, he was principally occupied. During and after his residence at Venice, he had come to disuse the traditional German practice of painting with the help of a whole school of assistants and apprentices. The first six years after his return, from 1506 to 1512, are pre-eminently the painting years of his life, in them, working with infinite preliminary pains, and, as it seems almost entirely with his own hands, he produced what are accounted his four capital works,—the Adam and Eve, painted in 1507; of this it has been disputed whether a version at Madrid or one in the Pitti Palace at Florence is the original; the Ten Thousand Martyrs of Nicomedia, painted for the elector Frederick of Saxony in 1508, and now in the imperial gallery at Vienna, a rich altar-piece representing the Assumption of the Virgin, with portraits of the donor and his wife and other accessory subjects, executed for Jacob Heller, a merchant of Frankfort, in 1509—this was afterwards replaced, at Frankfort, by a copy, and the original transported to Munich, where it perished by fire in 1674, and lastly, the Adoration of the Trinity by all the Saints, a composition of many figures commissioned for a chapel dedicated to All Saints in an almshouse for decayed tradesmen at Nuremberg, and completed in 1511—this is, now one of the glories of the Belvedere at Vienna. In this same year, 1511, Dürer brought out his three great woodcut books in folio form together—the Apocalypse in a second edition, the Great Passion, and the Life of the Virgin for the first time complete. In 1512, he painted two pictures for his native town, the historical portraits of Charlemagne and the emperor Sig-

mund, which are now to be seen in the Germanic Museum of Nuremberg. The two or three years next following this are for Durer years, above all things, of engraving on metal. Of the sixteen pieces composing the Little Passion on Copper, perhaps the best invented and certainly the most brilliantly executed of all his gospel histories, ten were executed in 1512 and the last six in 1513. Of the many devotional figures of the Virgin and Child cut on copper by Durer at various times of his career, several of the most pathetic and carefully finished date from about the same time. Now, also, he began to repeat with greater persistency the experiment, which he had first tried some years before, of working by the method, then newly invented, of the etcher, that is, of biting the lines of his drawing with acid upon metal instead of cutting them with the burin. And these, again, are the years of those three master-pieces of his mind and hand, the Melancholia, the Knight with Death and the Devil, and the St Jerome reading in his Cell. These engravings are too well known to need description. The first two, by their earnest and enigmatic significance, have fascinated minds of every class, and given rise to an infinity of discussion. It is nearly certain that in these three plates, of almost the same size, date, and manner, and of equal technical perfection, we have three out of four projected illustrations of the Human Temperaments, as they were divided by mediæval science—the Melancholic, the Sanguine, the Phlegmatic, and the Choleric. Melancholy being intended to stand at the head of the series (although it is dated 1513, and the Knight 1512), has the numeral I written after the name Melancholia; the winged genius, in whom the qualities of this temperament are incarnated, is seated darkly musing among symbolic instruments of science. She seems an incarnation of the new spirit of the age, the spirit of solemn and resolute search. The subject of the Knight, being intended to illustrate the sanguine temperament, has the initial S written in the corner. To some students this steadfast rider has seemed a type of the righteous man undismayed by the powers of darkness that beset him, to others of the evil man whom fate and retribution are about to overtake at last. Some have read the initial S as designating one of the first soldiers of the Reformation, Franz von Sickingen, others as designating one of the most infamous of robber nobles, Sparnecker. But indeed the subject is not thus definitely to be interpreted in either sense; the piece is but one, and the most pregnant and impressive, interpret it how you will, of the thousand emblems with which the Northern imagination in this age commemorated the power of Death, and proclaimed how he is for ever dogging at the heels of strong and weak, the just man and the unjust alike. St Jerome, the Father of the church to whom Renaissance Christianity turned with the greatest devotion, and whom the labours of Erasmus had made familiar in especial to the humanists of the North, serves as the natural type of the phlegmatic or student temperament. No fourth subject seems to have been attempted to complete the set. The reason of this may have been the call which at this time began to be made on Dürer's industry by another kind of work. The five years between 1514 and 1519 are devoted above all things to woodcut work, on commission from the emperor Maximilian, who had resided for some time at Nuremberg in 1512, and whose personal favour and friendship Durer from that time enjoyed. With the learned co-operation of Johannes Stabius, he presently commenced a scheme of design for wood engraving in honour of Maximilian more vast and laborious than either Burgkmair's schemes of illustration to the *Weisskuning* or *Schäufelein's* to the *Theuerdank*. This is the prodigious work known as the Gate of Honour, on it, and on the Car of Honour, and on portions of the Triumphal Procession, all of which

belonged to the same great scheme (other portions of the Procession being the work of Burgkmair) Durer was chiefly engaged for four or five years. One of the most delightful memorials of his activity in the service of the emperor is the famous *Prayer-Book of Maximilian*, a volume decorated by Durer's hand with marginal arabesques of an inexhaustibly quaint and various invention, this is now preserved at Munich, and is known by more than one modern edition published in facsimile. His few paintings remaining from this period show a manifest falling off in labour and completeness from those of the period just preceding. In 1518 the Diet of Augsburg brought Maximilian to that city, and there Dürer was in attendance on him. A noble portrait drawn in charcoal, and subsequently used for an engraving in wood, carries a note in the artist's handwriting to the effect that it was done from the emperor at Augsburg "in his little room up at the top in the palace."

In 1519 Maximilian died. In the next year the desire of Durer to secure from his successors a continuance of the patronage and privileges granted during his lifetime, together with an outbreak of sickness in Nuremberg, gave occasion to the master's third and last journey from his home. On the 12th of July 1520 he set out for the Netherlands, with his wife and her maid, in order to be present at the coronation of the young emperor Charles V., and if possible to conciliate the good graces of the all-powerful regent Margaret. In the latter part of his aim Durer was but partially successful. His diary of his travels enables us to follow his movements almost day by day. He travelled by the Rhine to Cologne, and thence by road to Antwerp, where he was splendidly received and lived in whatever society was most distinguished, including that of Erasmus of Rotterdam. Many portrait drawings of persons who sat to him in these days are preserved. Besides going to Aachen for the coronation, he made excursions down the Rhine from Cologne to Nunneguen, and back overland by Herzogenbusch; to Brussels, to Bruges and Ghent; and to Zealand with the object of seeing a natural curiosity, a whale reported ashore. The vivid account of this last expedition given in his diary contrasts with the usual dry entries of interviews and disbursements. A still more striking contrast is the passionate outburst of sympathy and indignation with which, in the same diary, he comments on the supposed kidnapping of Luther by foul play on his return from the Diet of Worms. Without being one of those who in his city took an avowed part against the old ecclesiastical system, and probably without seeing clearly whether the religious ferment of the time was tending—without, that is, being properly speaking a Reformer—Durer in his art and all his thoughts was the incarnation of those qualities of the Teutonic character and the Teutonic conscience which resulted in the Reformation; and personally, with the fathers of the Reformation he lived in the warmest sympathy.

On the 12th of July 1521 Dürer reached home again. The remaining seven years of his life were occupied chiefly with the preparation of the scientific writings of which we have already spoken; with engraving on copper, in a style of consummate care and power, several portraits of his friends, among them the elector Frederick, Pirckheimer, Erasmus, and Melanchthon; and with the execution of those two paintings by which, perhaps, his powers in this highest branch of his art are best known, the figures of St Paul with St Mark and St John with Peter. These are now in the Munich gallery, and exhibit at their greatest Durer's earnest and pregnant conception of character, with a majesty in the types and a grandeur in the gesture and drapery which in his earlier career he had never yet attained. Each apostle or evangelist represents a "temperament,"—John the melancholic, Peter the phlegmatic, Paul the sanguine,

DURHAM

VOL. VII

and Mark the choleric; and it is characteristic of Durer's thought that Peter is put in the background, standing off a book held open by John, the favourite evangelist of the Reformation and of Luther; in this representation of John some have recognized the features of Melancthon, its likeness to the poet Schiller is a coincidence much more obvious. These various classes of work were carried on in the face of failing health. In the canals of the Low Countries Durer had caught a fever, of which he never shook off the effects. The evidence of this we have in his own written words, as well as in a sketch which he drew to indicate to some doctor with whom he was in correspondence the seat of his suffering; and again, in the record of his physical aspect—the shoulders already somewhat bent, the features somewhat gaunt, the old pride of the abundant locks shorn away—which is preserved in a portrait engraved on wood just after his death, from a drawing made no doubt not long previously. That death came suddenly, so suddenly that there was no time to call his dearest friends to his bedside, on the night of the 6th of April 1528. Durer was buried in the vault belonging to his wife's family, but since disturbed, in the burying-ground of St John at Nuremberg. He left a name that will be honoured by the latest posterity, and a place that nothing could fill in the affections of his noblest contemporaries. This is the grave and feeling *Requiescat* of Luther, in a letter written to their common friend, Eoban Hesse.—"As for Durer, assuredly affection bids us mourn for one who was the best of men, yet you may well hold him happy that he has made so good an end, and that Christ has taken him from the midst of this time of troubles, and from yet greater troubles in store, lest he, that deserved to behold nothing but the best, should be compelled to behold the worst. Therefore may he rest in peace with his fathers: Amen."

The principal extant paintings of Durer, with the places where they are to be found, have been mentioned above. Of his drawings, by far the richest collection is in the Albertina Palace at Vienna; the next richest is probably that of the British Museum where a large volume, forming part of Lord Arundel's collection, is preserved. By the acquisition of the Posonyi-Hullot collection, the Berlin Museum has now (1877) taken certainly the third place. The Louvre also possesses some good examples, and many others are dispersed in various public collections, as at Munich, Hamburg, Bremen, Basel, Milan, and Florence, as well as in private hands all over Europe.

The principal editions of Durer's theoretical writings are these:—*GEOMETRY AND PERSPECTIVE*.—*Underweysung der Messung mit dem Zirckel und Richtscheit, in Linien, Ebenen und ganzen Corporen*, Nuremberg, 1525. A Latin translation of the same, with a long title, Paris, Wechel, 1532, and another ed in 1555. Again in Latin, with the title *Institutionum geometricarum libri quatuor*, Arnheim, 1605.

FORTIFICATION.—*Ettliche Underricht zur Befestigung der Schloss, Stadt, und Flecken*, Nuremberg, 1527, and other editions in 1530 and 1538. A Latin translation, with the title *De urbis, arcibus, castellisque muniendis ac condendis*, Paris, Wechel, 1535.

HUMAN PROPORTION.—*Hierin sind begriffen vier Bücher von menschlicher Proportion*, Nuremberg, 1548. Latin translation. *De Symetria partium in rectis formis humanorum corporum libri in latinum conversi, de varietate figurarum, &c., libri II*, Nuremberg, 1532.

The private literary remains of Durer, his diary, letters, &c., were first published, partially in Von Murr's *Journal zur Kunstgeschichte*, Nuremberg, 1785–1787; afterwards, in Campe's *Reliquien von A. Dürer*, Nuremberg, 1827, and again, carefully edited by Professor Moritz Thausing, in the *Quellenschriften für Kunstgeschichte und Kunsttechnik*, Vienna, 1872.

The principal remaining literature of the subject will be found in the following books and treatises, the elaborate monograph of Professor Thausing being the latest, and by far the fullest and most ingenious of them all.—Neudorfer, Johann, *Schreib- und Rechenmeister zu Nürnberg, Nachrichten über Künstlern und Werkleuten daselbst*, Nuremberg, 1547, republished in the Vienna *Quellenschrift*, 1875; Schenkl, Chr., *Vita Antonii Kressen*, 1515, reprinted in the collection of Pirckheimer's works, Frankfurt, 1610. Wimpfeling, *Epitome rerum Germanicarum*, ch. 68, Strassburg, 1565; Sandart, Joachim von, *Deutsche Academie*, Nuremberg, 1675, Doppelmayr,

Historische Nachricht von den Nürnbergischen Mathematicis und Künstlern, Nuremberg, 1730, Von Murr, Chr G., *Journal zur Kunstgeschichte*, as above, Bartsch, Adam, *Le Peintre-Graveur*, vol. vii Vienna, 1808, Passavant, J P., *Le Peintre-Graveur*, vol. iii Leipzig, 1842, Roth, J F., *Leben Albrecht Dürer's*, Leipzig, 1791, Heller, *Das Leben und die Werke Albrecht Dürers*, vol. ii., Bamberg, 1827–1831, Von Eye, Dr A., *Leben und Werke Albrecht Dürer's*, 2d ed., Nordlingen, 1869, Hansmann, A., *Dürer's Kupferstiche, Radirungen, Holzschnitte und Zeichnungen*, Hannover, 1861; Von Zahn, A., *Dürer's Kunstlehre*, Leipzig, 1866, Allihn, Max., *Dürer-Studien*, Leipzig, 1871, Nagler, G V., *Albrecht Dürer und seine Kunst*, Munich, 1827, Rettberg, R von, *Nürnberg's Kunstleben*, Stuttgart, 1854, Rettberg, R von, *Dürer's Kupferstiche und Holzschnitte*, Munich, 1876, Heaton, Mrs Charles, *The History of the Life of Albrecht Dürer of Nuremberg*, London, 1872, Scott, W B., *Albrecht Dürer, his Life and Works*, London, 1872, Thausing, Prof Moritz, *Dürer, Geschichte seines Lebens und seiner Kunst*, Leipzig, 1876, W Schmidt in Dolme's *Kunst und Künstler des Mittelalters und der Neuzeit*, Leipzig, 1877, *Œuvres de Albert Dürer reproduit et publié par Amand-Durand, texte par Georges Duplessis*, Paris, 1877 (S C.)

D'URFEY, THOMAS, more generally known by the familiar name of Tom d'Urfey, an English satirist and song-writer, was descended from a family of French Huguenot refugees, and was born at Exeter. The year of his birth is unknown. He was originally bred to the law, which he forsook for the more congenial employment of writing plays and songs. His humour both in writing and in singing the latter procured him access to the highest circles, and made him a favourite even at court. Addison in the *Guardian* (No. 67) relates that he remembered more than once to have seen Charles II. leaning on Tom d'Urfey's shoulder and humming over a song with him. He was a strong Tory and Protestant, and it is said that his songs had considerable influence in strengthening the cause of his party. His dramatic pieces, numbering upwards of thirty, were well received, but were so licentious that none of them kept the stage after the dissolute period for which they were written. D'Urfey, by imprudence and extravagance, became poor as he grew old; and having prevailed on the managers of the playhouse to act his comedy of the *Plotting Sisters* for his benefit, Addison wrote the above mentioned paper in the *Guardian*, with another (No 82) giving a humorous account of his eccentricities, in order to procure him a full house. He died at an advanced age in 1723. His songs, published in 6 vols., under the title of *Pills to Purge Melancholy*, were reprinted in fac-simile in 1872.

DURHAM, COUNTY PALATINE OF, one of the northern Palatines of England. The county is triangular in form, its eastern limit or base being a coast-line exposed to the German Ocean. It is separated from Northumberland chiefly by the Tyne and its tributary the Derwent, and from Yorkshire by the Tees. Towards its western extremity it joins Cumberland and Westmoreland. Its greatest length is 45 miles, and its greatest breadth 36 miles, and it contains an area of 1012 square miles, or 647,592 acres. It is divided into four wards,—Chester and Easington in the north, and Darlington and Stockton in the south. There were formerly three outlying portions of the county, shown in old maps, and known as North Durham (including Northamshire and Islandshire), Bedlingtonshire, and Crayke. These were attached to the county as having formed parcels of the ancient "patrimony of St Cuthbert," of which the land between Tyne and Tees was the chief portion.

Physical Features.—The western angle of the county is occupied by spurs of the Pennine chain, and hence is mountainous, with black, naked, and barren regions, from which issue numerous streams flowing to the sea. The elevations vary from 1000 to 2196 feet. There are some beautiful and fertile valleys in the eastern and central parts, pleasantly varied with hill and dale, and alternately appropriated to corn and pasture. Extensive tracts, principally in the western part of the county, are waste, but rich in minerals. In the southern districts the area of cultivation

has been considerably increased within the last few years. The ancient common fields belonging to the townships are now mostly inclosed. Draining having been carried on to a great extent, there is very little marshy ground left. Near the river Tees, and in some places bordering on the other rivers, the soil is loam or a rich clay. At a farther distance from these rivers it is of an inferior quality, with patches of gravel interspersed. The hills between the sea and an imaginary line from Barnard Castle on the Tees to Alansford on the Derwent, are covered with a dry loam, the fertility of which varies with its depth. From this line westward the summits as well as the sides of the hills are in great part moorish wastes.

At the distance of about three miles from Darlington, at Oxenhall, are cavities in the earth, called "Hell Kettles." There are similar natural pits in the neighbourhood of Ripon, and elsewhere. The diameter of the largest is not less than 114 feet, and that of the least 75. About five miles from Hartlepool is one of the most singular clusters of rocks in the north of England, called "Black Halls," formed by the force and constant action of the waves, which have separated enormous masses of the magnesian limestone, washing some entirely away, but leaving others standing, like vast towers. In some places the rock is perforated so as to form curious arches.

The only considerable river, beside those just mentioned, is the Wear, which rises in the western hills and flows past Durham to join the sea at Bishop-Wearmouth and Monk-Wearmouth, which places unite with Sunderland to form one great town. The Team, which gives its name to the Team Valley Railway, is a mere rivulet.

Trees are chiefly confined to the parks and seats of the nobility and gentry, but many plantations have been made of late years. The banks of the rivers and brooks, particularly in the vicinity of Durham, are fringed with wood of long growth and much value, and the deep wooded *denes* or ravines which open on to the sea-coast, each having a small stream at the bottom, are very characteristic. Castle Eden dene is about four miles in length, and famous for its beautiful trees and wild flowers.

Minerals.—The western hills are composed of carboniferous limestone, succeeded eastward by millstone grit, coal-measures, magnesian limestone, and new red sandstone. The south-east portion of the limestone is covered with sand, resulting from disintegration of the coal-measures and often showing black beds of coal-detritus. The mountain limestone contains productive veins of lead ore, which are extensively worked, also zinc ore. The beds of coal in the coal-measures are from 5 to 6 feet thick, and have long been source of enormous wealth. The mines are among the most extensive and productive in the kingdom. At Sunderland the coal trade furnishes employment for hundreds of vessels, independently of the "keels" or lighters which convey the coal from the terminus of the railroads and tramways to the ships. The seams now worked extend horizontally for many miles, and are from 20 to 100 fathoms beneath the surface. Under almost every seam of coal is a bed of fire-clay, full of roots of primeval forest trees. The basaltic formation known as the "Great Whin Sill" appears in Teesdale, and is also remarkable at Cockfield. A beautiful variety of the mountain limestone known as Frosterley marble, has for many centuries been quarried near Stanhope for decorative purposes, in Durham Cathedral and elsewhere taking the place of Purbeck marble, while in modern houses it is used chiefly for chimney-pieces. Ironstone is extensively worked in the neighbourhood of Swalwell and Winlaton. Some excellent quarries of slate for buildings have been opened in different parts of the county. The neighbourhood of Wolsingham abounds in fine millstones. The Newcastle

grindstones are procured at Gateshead Fell, and firestone of high estimation, for building ovens, furnaces, and the like, is obtained in various parts of Durham, and exported in considerable quantity.

Towns.—Besides the city of Durham, the county includes seven ancient boroughs, viz., Hartlepool, Barnard Castle, Bishop Auckland, Darlington, Sunderland, Stockton, and Gateshead. The large villages of Staindrop, Wolsingham, Stanhope, and Sedgfield are "market towns." The port of Stockton-upon-Tees is well situated for commerce. Hartlepool, being on a promontory, nearly encompassed by the German Ocean, which forms a capacious bay to the south of the town is advantageously placed for maritime traffic; Sunderland and South Shields are also well placed at the mouths of the Wear and Tyne.

No county in England presents a closer network of railways than Durham. The York, Newcastle, and Berwick trunk line enters the country south of Darlington, and continues due north until at Gateshead it crosses the Tyne and enters Northumberland. From this a great many smaller lines diverge to the ports and mineral fields.

Agriculture.—Improvements in agriculture have been pursued with considerable spirit and success. On some spots of gravelly soil, turnips and barley are grown in almost perpetual succession, a crop of clover being sometimes interposed. The manures are chiefly lime and the produce of the fold-yard; and though abundance of sea-weed might be collected on the coast, as it was in mediæval times, the farmers now make but little use of it. The farms are of moderate size, few of them exceeding 200 acres. The largest portion of each is arable, except towards the western extremity of the county, where the whole is pasture. The farm houses are well situated and commodious; and improvements in farming and farming machinery keep pace with the age. The cattle of Durham have long been in great repute; in point of form, weight, produce of milk, and quickness of fattening, there are none better. The cows yield from 25 to 30 quarts of milk daily. The sheep also stand high in estimation, particularly the Tees-Water breed. The Wear-dale sheep are small, but their mutton is finely flavoured.

The following figures, taken from the Agricultural Returns for 1873 and 1876, show the acreage of the principal crops and the numbers of the live stock in the county in those years:—

	Corn Crops	Wheat	Oats	Barley and Buck	Green Crops	Turnips	Grass under rotation
1873	99,243	37,669	37,631	18,470	32,803	22,153	50,834
1876	91,109	28,359	35,815	23,070	33,616	22,196	58,170
		Horses.	Cattle.	Sheep	Pigs		
1873		16,204	62,452	224,714	12,653		
1876		17,486	61,028	202,109	12,189		

According to the Owners of Land Return, Durham was divided in 1873 among 34,317 separate proprietors, of whom the large proportion of 91 per cent. owned less than 1 acre—the average of England and Wales being 71 per cent. The gross rental of the land amounted to £2,889,152, or an average of £5, 11s. 2½d per acre—as compared with £3, 0s 2d., the average of England and Wales. This unusual value per acre is to be ascribed to the presence of minerals. The proprietors possessing more than 8000 acres were as follows:—duke of Cleveland, 55,837 acres, Ecclesiastical Commissioners, 26,868, Viscount Boyne, 15,310, earl of Durham, 14,664, marquis of Londonderry, 12,823; earl of Eldon, 11,841, John Bowes, 8313, dean and chapter of Durham, 8089.

Natural History.—Except in the moorlands of the west only a few scraps of the county have been left in their natural state, but these portions are of great interest to the student of natural history. The ballast-hills at Shields and Hartlepool are overgrown with aliens, many of which are elsewhere unknown in this country. Nearly fifty different

species have been found. *Cypripedium*, *Epipactis*, *Pyrola*, *Ophrys*, under the Jews of Castle Eden, are visited by butterflies found nowhere else in England, as *Oreia ablandina*, *Polyommatus salmacis*, and the little moth *Acidalia blomeraria*. The most interesting birds left are the dotterel (*Charadrius morinellus*), pied flycatcher (*Muscicapa lucicola*), and crossbill (*Loxia curvirostra*), which still breed occasionally in the west of the county. The siskin (*Chrysomitris spinus*) and black redstart (*Ruticilla tithys*) have reared their young near the city of Durham. The stock dove has within the last few years become not uncommon. Red grouse and black game are abundant in suitable localities, and one heronry still remains. But the shores of Durham are deserted by the sea fowl, which 200 years ago were so abundant by Tees and Tyne that, as an old writer says, "in tyme of breeding one can hardly sett his foote so warylye that he spoyle not many of theyr nestes." The badger and the otter still linger in one or two nooks; the last marten was killed in Weardale 30 years ago, and meantime the squirrel has become common. Stockton is almost the last retreat in England of the native black rat. Of the former abundance of deer, wild ox, and boar every peat bog testifies by its remains; the boar appears to have existed in the reign of Henry VIII., and records of red deer in the county may be traced down to the middle of the last century.

Antiquities of pre-Roman date, whether implements of stone or bronze, or sepulchral remains, are scarcely found except in the valley of the Wear. A very remarkable discovery was made some years ago at Heathery Burn Cave, near Stanhope, where, under a coating of stalagmite, were preserved a great many bronze weapons and other objects, including almost every article which appears to have been known in Britain at that remote period. One mile north of Eggleston are some remains of an ancient structure called the Standing Stones. This originally consisted of a cairn in the centre, surrounded by a trench, and that again encompassed by a circular arrangement of rough stones, many of which have been removed and broken to repair the roads. Near a brook, at a small distance, is a large barrow, crossed from east to west by a row of stones. There are frequent references to "Standing Stones" now gone in old charters, where they are referred to as marking boundaries. The principal Roman remains are connected with the ancient Watling Street, which entered the county by crossing the Tees at Pierce-bridge, and left it on crossing the Derwent just north of Ebchester. The boundaries of the four stations of Pierce-bridge, Binchester, Lanchester, and Ebchester, on the line of this road, may still be clearly discerned. At Lanchester there are considerable remains of masonry, and at Binchester the most perfect hypocaust in the north of England. Chester-le-Street, as its name indicates, occupies the site, now obliterated, of a Roman station, on a subsidiary Roman road; and there was a camp, still partly to be recognized, on "Maiden Castle Hill," near the city of Durham. Many Roman altars and sculptured stones from Lanchester and elsewhere are preserved in the chapter library at Durham. Roman altars, coins, &c., have been found at South Shields, as well as about the above-mentioned stations. To the Anglo-Saxon period are to be referred portions of the churches of Monk-Wearmouth and Jarrow, and numerous sculptured crosses, two of which are *in situ* at Aycliffe. The best remains of the Norman period are to be found in Durham Cathedral (the finest Norman building in England) and in the castle, also in some half-dozen parish churches. Of the Early English period are the eastern portion of the cathedral (see below), the fine churches of Darlington, Hartlepool, and St Andrew, Auckland, and portions of a few other churches. The Decorated and Perpendicular

periods are very scantily represented, on account, as is supposed, of the incessant wars between England and Scotland in the 14th and 15th centuries. The principal monastic remains, beside those surrounding Durham Cathedral, are those of its subordinate house or "cell," Finchale Priory, situated in a lovely valley by the Wear. The most interesting castles are those of Durham, Raby, Brancepeth, and Barnard. There are ruins of castlelets, or peel-towers, at Dalden, Lindworth, and Langley Dale. The hospitals of Sherburn, Greatham, and Kepyer, founded by early bishops of Durham, retain but very few ancient features.

The principal noblemen's seats are Raby Castle (duke of Cleveland), Lambton Castle (earl of Durham), Wynyard Castle (marquis of Londonderry), Ravensworth Castle (earl of Ravensworth), Brancepeth Castle (Viscount Boyne), and Whitham Hall (Sir Hedworth Williamson, Bart.)

The county is divided for parliamentary purposes into two divisions (North and South Durham), each of which returns two members. The northern division includes 20 polling-places, and the southern 33. The population has greatly increased within the last thirty years. In 1851 the inhabitants numbered 390,997; in 1861, 508,666; and in 1871, 685,089—353,117 males and 331,972 females. The increase between 1851 and 1871 amounts to 72½ per cent. The population is estimated at upwards of £50,000 in 1877.

History.—Before the arrival of the Romans the county formed part of the British territory of the Brigantes, which comprised all between Tyne and Humber. Then it became part of the Roman province *Maxima Caesariensis*. In Anglo-Saxon times it was included in *Bernicia*, in the kingdom of Northumbria. After the Norman Conquest it gradually acquired in one way or another that peculiar independence which was attached to "Counties Palatine." The bishops of Durham were temporal princes as well as spiritual rulers, exercising most of the royal prerogatives, such as paramount property in all lands, and supreme jurisdiction both civil and military, as in making war, right of forfeiture, levying of taxes, &c. These privileges could be the more readily conceded to this county on account of its remoteness from the metropolis, and its proximity to the hostile kingdom of Scotland, in order that the inhabitants, having justice administered at home, might not be obliged to go out of their county, and leave it open to an enemy's incursions. For they pleaded privilege not to pass over Tees or Tyne for military service, their special charge being, as was alleged, to keep and defend the sacred body of St. Cuthbert, whence they were called "Halifer folc" (Holy war folk). By an Act passed in the 27th year of Henry VIII. a heavy blow was struck at the regal powers which the bishops of Durham had enjoyed, and at the death of Bishop Van Mildert in 1835, an Act was passed whereby all temporal jurisdictions and privileges were declared to be for ever removed from the bishopric. Up to that time the bishops opened the assizes in person, as being still at the head of the administration of justice, the judges sitting by virtue of the bishop's writ. Durham is now included in the province of York, and in the north-eastern circuit. The principal county histories are those by Hutchison and Surtees, the latter incomplete, but, so far as it goes, it is a noble work, one of the very best of that class ever published. Murray's handbooks to the county and to the cathedral, though occasionally inaccurate, are full of interesting and valuable information.

DURHAM CITY, a municipal and parliamentary borough of England, and the chief town of the county of Durham, is situated on the River Wear (which is crossed there by four bridges), 14 miles S. of Newcastle and 60 miles N.N.W. of York. Though there was a small Roman camp at Maiden Castle Hill, about a mile distant, Durham itself dates only from the end of the 10th century, when the monks of Lindisfarne rested there with the body of St. Cuthbert, after wandering about with it almost all over the north of England. Soon afterwards a church was built by Bishop Eadmund, and the removal of the see from Lindisfarne thither, together with the growing fame of the incorruptible body of the saint, led to the rise of the city. The rocky peninsula on which Eadmund's church was founded, about 80 feet above the river, was called Dunholme (Hill Island),

which in Norman times was softened to "Dnresme," whence "Durham." The castle was erected by William the Conqueror in 1072, across the neck of the peninsula, so as to guard the church and monastery. In 1093 Ealdhune's

Plan of Durham.

church was rebuilt by Bishop Carleph, who changed the Anglo-Saxon establishment of married priests into a Benedictine abbey.

The Cathedral.—Carleph's grand Norman church still forms the main part of the cathedral buildings; but numerous additions have been made from time to time, the chief of which are—the Galilee or western chapel, of the Transitional period, the eastern transept or "Nine Altars" and the western towers (Early English), and the central tower (Perpendicular). Decorated and Perpendicular windows have, as is usual in old churches, been freely inserted. The interior presents the appearance, as Dr Johnson remarked, of "rocky solidity and of indeterminate duration," and combines, we may add, absolutely perfect proportion in all its original parts with a harmonious magnificence of detail in its massive columns, arches, and stone groining. It has recently been thoroughly cleaned, and supplied with much painted glass and very costly modern fittings, including a new organ built on the largest scale and of fine tone. Durham Cathedral, or "The Abbey," as old-fashioned residents still call it, has long been celebrated and still maintains its reputation for its choral services, as being at least equal to any in England in point of musical execution. This glorious building has been admirably illustrated in Carter's *Plates*, and in Billings's *Architecture of Durham Cathedral*. It is 507 feet in length, by 200 in extreme breadth, with a central tower 214 feet in height, and two smaller ones 138 feet high at the west end. The Galilee or western chapel was built by Bishop Pudsey between 1153 and 1195, and contains the supposed remains of the Venerable Bede. In the chapel of the Nine Altars are the remains of St Cuthbert, brought to light in 1827. The cathedral library, formerly the dormitory and refectories of

the abbey, contains a number of curious and interesting printed books, and MSS., and the portable altar, vestments, and other relics found in St Cuthbert's grave.

The see of Durham was long the richest bishopric in England. The total revenue of the dean and chapter during the seven years ending 1834 amounted to £36,937 a year. On the death of the incumbent in 1836, at the recommendation of the Ecclesiastical Commissioners, the income of the bishop was fixed at £8000 per annum—the surplus revenues of the see being reserved to form a fund for augmenting the incomes of the poorer bishops.

Arms of Bishopric.

Castle, &c.—The castle of Durham consists of a polygonal keep, now reconstructed to form a very inconvenient set of college rooms; the great hall built by Bishop Hatfield, which in some respects exceeds any hall in the older universities; the Norman hall, now cut up into rooms; the old Norman crypt chapel; Bishop Tunstall's chapel, at present in use; the Black Staircase, built by Bishop Cosin; and the kitchen, the gate-house, and other offices. These are grouped round a court very irregular in plan, and not less picturesque in general effect. Durham Castle was the chief residence of the bishops of the Palatinate, but is now appropriated to the uses of the university, with the exception of the state apartments, which are partly reserved for the bishop and for Her Majesty's judges of assize. The university was opened in 1833; an account of it will be found under UNIVERSITIES. Besides the cathedral, Durham has seven parish churches. There are also places of worship for Roman Catholics, and for various denominations of Protestants. The grammar school attached to the cathedral was founded by Henry VIII. in 1541, and possesses eighteen "king's scholarships," of the annual value of nearly £40 each. There are also several scholarships and exhibitions tenable at the universities. The original school-room is now used by the university of Durham; the new buildings are beautifully situated to the west of the city, and are very handsome and commodious, including residences for the head and second masters, and a school infirmary. Durham possesses flourishing diocesan training colleges for schoolmasters' and schoolmistresses, and about four miles to the west of the city is the great Roman Catholic College called St Cuthbert's College, Ushaw, the present representative of the old college at Douai.

The civil corporation of Durham and Framwellgate consists of the mayor, six aldermen, and eighteen councillors, with a recorder, a chaplain, and town clerk, two elective auditors, and two elective assessors. On the passing of the Corporation Act, 5 and 6 Will. IV. c. 76, the election of the eighteen councillors was vested in the citizens occupying houses and paying poor and other rates. The councillors so elected have to choose the six aldermen, and the aldermen and councillors have the election of the mayor. Four charters (all, except the third, preserved in the "Hutch" at the Guild Hall) have been granted to the city by different bishops of Durham—the first by Hugh Pudsey, confirmed by Pope Alexander III., 1179 or 1180; the second by Tobias

Corporation Seal.

Matthew, confirmed by James I.; the third by Nathaniel Lord Crew, 1684 (afterwards redelivered to the bishop, the corporation acting under the second charter); and the fourth by John Egerton, 1780

Durham can scarcely be said to have any staple trade or manufacture, though it possesses one carpet factory and one large mill for the preparation of "Durham mustard" It is now a very different place, socially, from what it was when there were twelve prebendaries with much larger incomes than the six canons now have, and when "The College" was a noted centre for dignified and liberal hospitality. At that time, canonical residence was kept with much more strictness than it is at present, and the prebendary in residence entertained guests of all classes. Noblemen and gentlemen then resided in houses in Framwellgate and Elvet, now let out into tenements and serving as the squalid homes of the very poorest class. The Bailey and Old Elvet are, however, still chiefly occupied by the upper classes, and Western Hill is a new and rapidly increasing suburb. The Palace Green is an open space having the cathedral on the south side, the castle, now University College, on the north, the Exchequer Buildings, now the university library, together with Bishop Cosin's library, on the west, and the museum, alms-houses, and other offices on the east. The museum contains an almost complete collection of British birds. Six out of the seven parish churches are ancient, and possess features of interest. The high banks of the river on which the cathedral and castle stand are richly wooded, and traversed in all directions by well-kept paths, which afford ever-changing views of wood, water, rocks, bridges, the cathedral, the castle, picturesque old houses, and terraced gardens.

In 1861 the municipal borough of Durham had within its area of 880 acres 2007 inhabited houses, with a population of 14,088. In 1871, the number of inhabited houses was 2349, and the population comprised 6956 males and 7450 females, or 14,406 in all. The parliamentary borough, which with an area of 967 acres had 14,833 inhabitants in 1871, returns two members to Parliament (J. T. F.)

DURHAM, JOHN GEORGE LAMBTON, FIRST EARL OF (1792-1840), born at Lambton Castle, Durham, on the 12th April 1792, was the eldest son of William Henry Lambton, MP for the city of Durham. It is noteworthy that the family to which he belonged had held the Lambton estate in uninterrupted male succession from the 12th century. Educated at Eton, he held for a short time a commission in a regiment of hussars. In 1813, soon after attaining his majority, he was returned to Parliament as representative of his native county. He was an advanced Liberal from the beginning to the end of his political career, and distinguished himself by his uncompromising opposition to the reactionary measures of the Tory Government. His political position was strengthened by his marriage in 1816 to the eldest daughter of Earl Grey. In 1819 he championed the rights of the people by his denunciation, in the House of Commons and at numerous public meetings, of the coercive measures proposed by the Government against the Chartists. In April 1821 he proposed in the House a scheme of parliamentary reform which was in some points, notably in regard to the redistribution of seats, more thoroughgoing than that which was carried eleven years later. The delicate state of his health compelled him in 1826 to proceed to Naples, where he resided for about a year. He was a prominent supporter of the Canning administration of 1827, and of that of Lord Goderich by which it was succeeded. When the latter fell to pieces owing to its inherent weakness in January 1828, Lambton's services were acknowledged by his elevation to the peerage as Baron Durham. On the accession of Lord Grey to power in 1830 Lord Durham obtained the

office of lord privy seal. He was one of a Cabinet committee of four who were intrusted with the preparation of the Reform Bill, the others being Sir James Graham, Lord John Russell, and Lord Duncannon. It was understood at the time that his influence was exerted to make the measure as liberal as possible, and in particular that he wished to introduce the ballot as one of its provisions. In the debates on the bill in the Lords he did not take the leading part that might naturally have been expected from the only peer who had been on the Cabinet committee for its preparation. This was owing partly to his own indifferent health and partly to grief at the death of his eldest son, the Master Lambton of one of Lawrence's most admired portraits. Continued ill-health led him to resign office in March 1833, when he was raised to the dignity of Viscount Lambton and earl of Durham. In the summer of the same year, however, he was able to undertake a special embassy to the court of St Petersburg, the chief object of which was to secure lenient treatment for the insurgent Poles. In this he was unsuccessful. When the party that had carried reform began to be divided, Lord Durham was generally regarded as a likely leader of the more advanced section, and a strongly radical speech which he delivered at the celebrated Grey banquet at Edinburgh in 1834 helped to strengthen his claims to the position. It took the form of a reply to a previous speech of Lord Brougham, whose enmity Lord Durham thus provoked. In 1837 he accepted the post of ambassador at St Petersburg, which he occupied for about a year. Meanwhile a very serious insurrection had broken out in Canada, and early in 1838 the Government found it necessary to suspend the colonial constitution and send out a new governor with special powers. Lord Durham was selected to undertake the difficult task, for which his extensive experience and his well-known advanced liberalism were supposed specially to qualify him. Somewhat hasty and irascible in his temperament, he unfortunately adopted measures which were beyond the powers conferred upon him by the special Act of Parliament under which he had been appointed. These measures were disapproved of by a vote of the House of Lords on the motion of Lord Brougham, who imported the bitterness of his earlier quarrel with Lord Durham into the debate, and the Government were compelled to disallow the ordinances in which they were embodied. Lord Durham was so deeply incensed at this that he took the extraordinary step of returning home without waiting for his recall, and the Government marked its disapproval of his conduct by directing that he should not receive the customary salute on landing in England. He defended his plan of administration in an able and elaborate report addressed to the queen, and his policy was practically justified by being adopted by his successor. He had returned to England in shattered health, and he died at Cowes, in the Isle of Wight, on the 28th July 1840.

DURIAN (Malay, *duri*, a thorn), the fruit of *Durio zibethinus*, a tree of the natural order *Sterculiaceæ*, which attains a height of 70 or 80 feet, has oblong, tapering leaves, rounded at the base, and yellowish-green flowers, and bears a general resemblance to the elm. The durio is cultivated in Sumatra, Java, Celebes, and the Moluccas, and northwards as far as Mindanao in the Philippines; also in the Malay Peninsula, in Tenasserim, on the Bay of Bengal, to 14° N lat., and in Siam to the 13th and 14th parallels. The fruit is spherical, and 6 to 8 inches in diameter, approaching the size of a large cocoa-nut; it has a hard external husk or shell, and is completely armed with strong pyramidal tubercles, meeting one another at the base, and terminating in sharp thorny points; these sometimes inflict severe injuries on persons upon whom the fruit may chance to fall when ripe. On dividing the fruit at the

sutures of the carpels, where the spines arch a little, it is found to contain five oval cells, each filled with a cream-coloured, glutinous, smooth pulp, in which are imbedded from one to five seeds about the size of chestnuts. The pulp and the seeds, which latter are eaten roasted, are the edible parts of the fruit. With regard to the taste of the pulp Mr Wallace remarks, "A rich butter-like custard, highly flavoured with almonds, gives the best idea of it, but intermingled with it come wafts of flavour that call to mind cream-cheese, onion-sauce, brown sherry, and other incongruities; . . . it is neither acid, nor sweet, nor juicy, yet one feels the want of none of these qualities, for it is perfect as it is." The fruit, especially when not fresh from the tree, has, notwithstanding, a most offensive smell, which has been compared to that of rotten onions or of putrid animal matter. The Dyaks of the Sarawak river in Borneo esteem the durian above all other fruit, eat it unripe both cooked and raw, and salt the pulp for use as a relish with rice.

DÜRKHEIM, a town in the Palatinate of the Rhine, near the foot of the Hardt Mountain, and at the entrance of the valley of the Isenach, 15 miles north-west of Spire, on the railway between Monsheim and Neustadt. Besides being the seat of various administrative offices, it possesses three churches and a synagogue, a town-hall occupying the site of the castle of the princes of Leiningen-Hartenburg, an antiquarian and a scientific society, a public library, and a high school. It is well known as a resort for invalids, who may either indulge in the grape-cure or have recourse to the salt-springs of Philippsbad in the neighbourhood, which not only supply the bathing establishment, but produce annually about 8000 cwt of marketable salt. The inhabitants have a good trade in wine, and manufacture oil, tobacco, glass, and paper.

As a dependency of the Benedictine abbey of Limburg, which was built and endowed by Conrad II., Dürkheim or Thurnheim came into the possession of the counts of Leiningen, who in the 13th century made it the seat of a fortress, and in the 14th inclosed it with wall and ditch. In the three following centuries it had its full share of the military vicissitudes of the Palatinate; but it was rebuilt after the French invasion of 1689, and greatly fostered by its counts in the beginning of next century. In 1794 its new castle was sacked by the French, and in 1849 it was the scene of a contest between the Prussians and the insurrectionists. The ruins of the abbey of Limburg are still to be seen about a mile S.W. of the town and in the neighbourhood rises the Kastanienberg, with the ancient rude stone fortification of the Heidenmauer or Heathen's Wall. Population in 1871, 5572.

DURLACH, a town of Baden, in the circle of Carlsruhe, $2\frac{1}{2}$ miles by rail from the city of that name, with which it is connected by a canal and an avenue of poplars. It lies on the left bank of the Pfalz, at the foot of the vineyard-covered Thurnberg, which is crowned by a watch-tower; and it possesses a castle erected in 1565 and now used as barracks, an ancient Rathhaus, a church with an excellent organ, an upper Bürgerschule, an orphan asylum, and in the market-place a statue of the margrave Charles II. Its inhabitants manufacture tobacco, beer, vinegar, and chicory, and engage in agriculture and gardening. A chalybeate spring is utilized at the bathing establishment of Amalienbad.

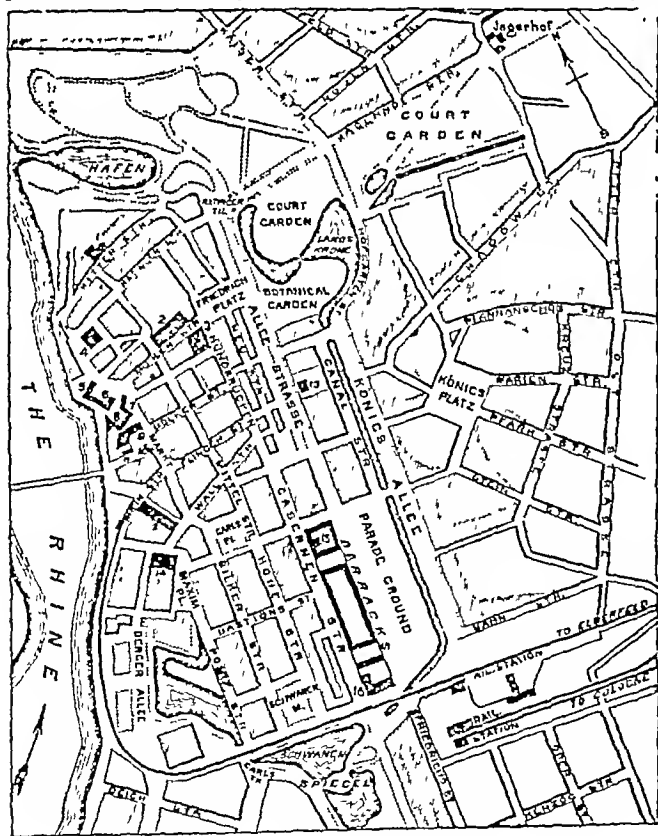

Durlach was bestowed by the emperor Frederick on Hermann V. of Zähringen as an allodial possession, but afterwards came into the hands of Rudolf of Hapsburg. It was chosen as his residence by the margrave Charles II., in 1565, and retained this distinction till the foundation of Carlsruhe in 1715, though it was almost destroyed by the French in 1688. In 1846 it was the seat of a congress of the liberal party of the Baden parliament; and in 1849 it was the scene of an encounter between the Prussians and the insurgents. Reichenbach the mechanician and Posselt the historian are natives of the town.

DURRA, or **INDIAN MILLET**, *Sorghum vulgare*, is a species of grass of the tribe *Andropogoneæ*. The terms *durra* and *zurru* are applied to the plant in Arabia; in India it is known as *jawari* (Hindustani), *jowari* (Bengali), *cholam* (Tamil), and *jonna* (Telugu), and in the West Indies as Negro or Guinea Corn. It is a strong grass, growing to a height of from 4 to 8 or even 16 feet; the leaves are sheathing, solitary, and about 2 inches broad and $2\frac{1}{2}$ feet in length; the panicles are contracted, dense, and hermaphrodite; and the seeds, which are inclosed in husks, and protected by awns, are round, hard, smooth, shining, brownish-red, and somewhat larger than mustard seeds. The plant is cultivated in various parts of India and other countries of Asia, in the United States, and in the south of Europe. Its culms and leaves afford excellent fodder for cattle; and the grain, of which the yield in favourable situations is upwards of a hundredfold, is used for the same purposes as maize, rice, corn, and other cereals. Allied species are *S. bicolor*, much valued in India as a forage-plant, and *S. saccharatum*, commonly called sorghum or Chinese sugar cane, which is extensively cultivated in China, North India, and Africa. The latter species is grown in America chiefly for the manufacture of molasses from its juice, and in France as a source of alcohol. The total quantity of sorghum molasses made in the United States in 1870 has been estimated at 16,050,089 gallons.

DUSSEK, **JOHANN LUDWIG** (1761–1812), pianist and composer, was born at Czeslau, in Bohemia, on the 9th February 1761. His father, Johann Joseph Dussek, a musician of high reputation, was organist and choir-master in the collegiate church of Czeslau, and several other members of the family were distinguished as organists. He had thus the most favourable opportunity for the development of the musical talent which he displayed almost from infancy. Under the careful instruction of his father he made such rapid progress that he appeared in public as a pianist at the age of six. A year or two later he was placed as a choir boy at the convent of Iglau, and he obtained his first instruction in counterpoint from Spenar, the choir-master. When his voice broke he entered on a course of general study, first at the Jesuits' college, and then at the university of Prague, where he took his bachelor's degree in philosophy. During his curriculum of two and a half years he had paid unremitting attention to the practice and study of his art, and had received farther instruction in composition from a Benedictine monk. In 1779 he was for a short time organist in the church of St Rombaut at Mechlin. At the close of this engagement he proceeded to Holland, where he attained great distinction as a pianist, and was employed by the stadtholder as musical instructor to his family. While at the Hague he published his first works in the form of several sonatas and concertos for the piano. He had already composed at the age of thirteen a solemn mass and several small oratorios, which still exist in manuscript. In 1783 he visited Hamburg, and placed himself under the instruction of Emmanuel Bach. Though he believed himself to have derived great benefit from this, it may be questioned whether his genius was not fettered rather than stimulated by the enthusiastic veneration with which he regarded his model. From Hamburg he proceeded to Berlin, where his powers as a pianist met with their accustomed recognition. After spending two years in Lithuania in the service of Prince Radziwill, he went in 1786 to Paris, where he remained, with the exception of a short period spent at Milan, until the outbreak of the Revolution, enjoying the special patronage of Marie Antoinette and great popularity with the public. Towards the close of 1789 he removed to London, where three years later he married a daughter of Dominico Corri, who was

herself a clever harpist and pianist. In London he obtained his greatest success alike as composer, performer, and teacher. Unfortunately, however, he was tempted by the large sale of his numerous compositions to open a music-publishing warehouse in partnership with Montague Corri, a relative of his wife. The result was injurious to his fame and disastrous to his fortune. Writing solely for the sake of sale, he composed many pieces that were quite unworthy of his genius, and, as he was entirely destitute of business capacity, bankruptcy was inevitable. In 1800 he was obliged to flee to Hamburg to escape the claims of his creditors. Some years later he was attached in the capacity of musician to the household of Prince Louis Ferdinand of Prussia, with whom he formed an intimate friendship. On the death of his patron in 1806 he passed into the service of Prince Ysenburg as court musician. In 1809 he went to Paris to fill a similar situation in the household of Prince Talleyrand, which he held until his death in March 1812. Dussek had an important influence on the development of pianoforte music. As a performer he was distinguished by the purity of his tone, the combined power and delicacy of his touch, and the facility of his execution. As a composer he possessed a distinct individuality of style, and, while much that he wrote has little value, his best works rank high among pianoforte classics. His sonatas known as *The Invocation*, *The Farewell*, and *The Harmonic Elegy*, though not equally sustained throughout, contain movements that have scarcely been surpassed for solemnity and beauty of idea. Two operas, which he composed during his residence in London, were failures.

DÜSSELDORF, a town of Prussia, at the head of a government in the province of the Rhine, on the right

Plan of Düsseldorf

| 7 Hauptwache | 15. Garrison Church. |
| 8. Old Castle | 16. Post Office. |

bank of the river, 25 miles below Cologne. It is divided

into four portions,—the Old Town, the Karlstadt, which dates from 1787 and is called after the electoral prince Charles Theodore, the New Town, which was in process of formation from 1690 to 1716, and the Friedrichsstadt, laid out within recent years. New streets are rapidly stretching out in all directions, and the villages of Pempelfort, Bilk, and Derendorf are already almost incorporated. Within the area of the town proper there are numerous open grounds and public squares, which prevent the regularity of its plan degenerating into monotony: the market-place, with the colossal bronze statue of the electoral prince Johann Wilhelm, the parade, the Allée Strasse, the King's Alley, and the King's Platz may be specially mentioned. Of the ten churches the most noticeable are—St Andrew's, formerly the Jesuit or court church, with frescoes by Hubner, Deger, and Mucke, and the embalmed bodies of several of the electors, St Lambert's, with a tower 180 feet high, and containing monuments in honour of Duke William IV. and Voetius, and Maximilian's, with frescoes by Settegast and others. Besides the old ducal palace, laid in ruins by the French in 1794, but restored in 1846, the secular buildings comprise the former Jesuit college, now occupied by the administrative offices, a town-house dating from 1567, a penitentiary, a lunatic asylum, several hospitals and infirmaries, a theatre completed in 1875, a music hall, a gymnasium, and a polytechnical school. The town also possesses a library of 50,000 volumes, and is the seat of a great number of commercial and intellectual associations, but to nothing is it more indebted for its celebrity than to the Academy of Painting. This famous institution, originally founded by the electoral prince Charles Theodore in 1767, was reorganized by King Frederick William in 1822, and has since attained a high degree of prosperity as a centre of artistic culture. From 1822 till 1826 it was under the direction of Cornelius, a native of the town, from 1826 to 1859 under Schadow, and from 1859 to 1864 under Bendemann. From Bendemann's resignation it continued in the hands of a body of curators till 1873, when Wiselinius of Weimar was chosen director. The noble collection of paintings which formerly adorned the Düsseldorf gallery was removed to Munich in 1805, and has not since been restored, but there is no lack of artistic treasures in the town. The academy possesses 14,000 original drawings and sketches by the great masters, 24,000 engravings, and 248 water-colour copies of Italian originals; the municipal gallery contains valuable specimens of the local school; and the same is the case with the Schulte collection. The principal names are Cornelius, Lessing, Achenbach, Baur, Tidemann, and Knaus. An annual exhibition is held under the auspices of the Art Union, and the members of the Artist's Society, or *Malkasten*, as they are called, annually celebrate festivities and masquerades of a remarkable description. Not only is Düsseldorf situated in the greatest manufacturing province of Prussia, but it is itself the seat of various important industries,—cotton and carpet weaving, iron-founding, wire-drawing, sugar-refining, brewing, distillation, and the making of pianos and carriages. The surrounding country is largely devoted to market-gardening, and the Düsseldorf mustard is in special repute. A very extensive trade is carried on both by river and by rail; the port was declared free in 1829, and is consequently one of the most frequented on the Rhine. The Düsseldorf Steam-boat Company maintains regular communication with Mayence on the one hand and Rotterdam on the other. A little to the north of the town lies the village of Düsseldorf, with Count Reeke Volmarstein's establishment for homeless children in the former Trappist monastery; and in the suburban village of Pempelfort is the *Jägerhof*, the residence at one time of

Prince Frederick of Prussia, and afterwards of the prince of Hohenzollern Sigmaringen. In 1780 the number of inhabitants was about 8000, by 1831 it was over 23,000. The census of 1861 gave 41,290 (of which 3376 were military), that of 1871, 69,348.

Dusseldorf, as the form of the name—the village on the Düssel—clearly indicates, was long a place of small consideration. In 1288 it was raised to the rank of a town by Count Adolf of Berg, from his successors it obtained various privileges, and in 1385 was chosen as their residence. After it had suffered greatly in the Thirty Years' War and the war of the Spanish succession, it recovered its prosperity under the patronage of the electoral prince John William of the Palatinate, who dwelt in the castle till the restoration of Heidelberg. In 1794 the town was violently bombarded by the French, and after the peace of Lunéville it was deprived of its fortifications. In 1806 it became the capital of the Napoleonic duchy of Berg, and in 1815 it passed with the duchy into Prussian possession. Among its celebrities are George and Friedrich Heinrich Jakobi, Schenk, Heine, Varnhagen, Cornelius, Camphausen, and H. von Sybel.

DUTENS, LOUIS (1730–1812), a French writer of some celebrity, was born at Tours, of Protestant parents, January 15, 1730. In his youth he devoted himself to poetry, and in 1748 he composed a tragedy, entitled *The Return of Ulysses to Ithaca*, which failed in Paris, but was represented with great applause at Orleans. The author, however, soon became sensible of the faults of his work, and abandoned a species of composition in which he found he was not destined to excel. He soon afterwards went to England with an introduction to Pitt, which he had received from a sister of the statesman. His first residence in London was brief, but he soon returned and obtained a situation as tutor in a private family. The father of the pupil was a man of considerable literary and scientific attainments, who instructed him in those branches of knowledge in which he was deficient. In this manner he learnt Greek and mathematics, and studied the Oriental languages, and Italian and Spanish. Soon after the termination of this engagement he was appointed chaplain and secretary to Mr Mackenzie, the English minister at the court of Turin, and left England in October 1758. In 1760, when Mr Mackenzie returned to England, the secretary remained at Turin as chargé d'affaires, until 1762, when he returned to England and attached himself to the family of Lord Bute, who, before retiring from office in 1763, procured him a pension. He again went to Turin as chargé d'affaires, and during this second mission he undertook the task of collecting and publishing a complete edition of the works of Leibnitz (Geneva, 6 vols 1769) and wrote his work on the *Discoveries of the Ancients*. On again returning to England he attached himself to the duke of Northumberland, who procured him the living of Elsdon, in Northumberland. He accompanied the duke's son, Lord Algernon Percy, in his travels through France, Italy, Germany, and Holland, and while at Paris he was chosen a member of the Academy of Inscriptions, in 1775. In the same year he was made a fellow of the Royal Society. In 1776 he returned to England, and soon afterwards accompanied Mr Mackenzie and his wife on a tour to Naples. On his return Dutens was invited by Lord Mountstuart, who had been appointed envoy extraordinary, to accompany him to Turin, and found himself for the third time chargé d'affaires at that court, during a short absence of the envoy. From Turin he went to Florence, and thence to Rome. He was in Paris in 1783, and returned to London the following year. The revenue he derived from his living amounting to £800 per annum, together with a considerable legacy left him by Mr Mackenzie, and estimated at £15,000, enabled him to pass the remainder of his life in affluence. He died at London, May 23, 1812.

The principal works of Dutens were his *Recherches sur l'origine des Découvertes attribuées aux Modernes* (1766, 2 vols 8vo), *Appel au bon Sens* (London 1777, 8vo), directed in defence of Christi-

anity against the French philosophers, and published anonymously; *Explication de quelques médailles de Peuples, de Villes, et de Rois, Grecques et Phéniciennes* (1773, 4to); *Explication de quelques médailles du cabinet de Duane* (1774, 4to), *Troisième Dissertation sur quelques médailles Grecques et Phéniciennes* (1776, 4to), *Logique, ou l'Art de raisonner* (1773, 12mo), *Des pierres précieuses et des pierres fines, avec les moyens de les connaître et de les évaluer* (1776, 12mo); *Itinéraire des routes les plus fréquentées, ou Journal d'un Voyage aux principales Villes d'Europe* (1775, 8vo), frequently republished, *Considérations Théologiques sur les moyens de réunir toutes les Églises Chrétiennes* (1798, 8vo), *Ouvrages mêlés*, containing his most important works published up to the date (London, 1797, 4 vols 4to), *L'Ami des étrangers qui voyagent en Angleterre* (1789, 8vo), *Histoire de ce qui s'est passé pour le rétablissement d'une régence en Angleterre*, (1789, 8vo), *Recherches sur le tems le plus reculé de l'usage des Voutes chez les anciens* (1795), *Mémoires d'un Voyageur qui se repose* (Paris, 1786, 3 vols 8vo). The first two volumes of the last named work contain the life of the author, written in a romantic style, the third bears the title of *Dutensiana*, and is filled with remarks, anecdotes, and bon-mots. (See memoir of Dutens in the *Gentleman's Magazine* for 1812.)

DUTROCHET, RENÉ JOACHIM HENRI (1776–1847), a French physiologist and natural philosopher, was born at Château de Néon, Poitou, November 14, 1776, and died at Paris, February 4, 1847. In 1799 he entered the military marine at Rochefort, which, however, he soon deserted to join the Vendean army. In 1802 he began the study of medicine at Paris, and in 1808 he was made physician to Joseph Bonaparte, king of Spain. Appointed chief physician to the hospital at Burgos, he distinguished himself during the prevalence of typhus in that city. He returned in 1809 to France, where he devoted himself to the study of the natural sciences. The number of his scientific publications, which relate to a great variety of topics, is very great. His *Recherches sur l'accroissement et la reproduction des végétaux*, published in the *Mémoires du Muséum d'Histoire naturelle* for 1821, procured him in that year the French Academy's prize for experimental physiology. In 1837 appeared his *Mémoires pour servir à l'histoire anatomique et physiologique des végétaux et des animaux*, a collection of all his biological papers of any importance.

DUVAL, JULES (1813–1870), a French economist, was born at Rodez, in the department of Aveyron, received his early education at the college of St Geniez d'Olt, passed as advocate at the age of twenty-three, and for eight years held an official position first at St Affrique and afterwards in his native town. On the pacification of Algeria he took an active part in the foundation of the Union Agricole d'Afrique, and in 1847 he established an agricultural colony in the plain of Siz. Obligated by ill health to abandon in 1850 the personal charge of the enterprise, he did not leave the country, but in 1852 became editor of the *Echo d'Oran*, and from 1858 to 1861 acted as member and secretary of the general council of the province of Oran. Removing to Paris in the latter year, he there devoted himself to the literary exposition of his views; and among numerous other enterprises founded and edited till his death the *Économiste Français*, a weekly periodical devoted to the treatment of all matters connected with colonization and social reform, which bore his favourite device of *libre et harmonique essor des forces*. He was killed at Plessis-lès-Tours in a railway accident on the 20th of September 1870, while on his way to his native town.

Besides a series of contributions to the *Journal des Débats* and the *Revue des Deux Mondes*, he wrote *Tableau de l'Algérie* (1854), *Les colonies et l'Algérie au concours général et national d'agriculture de Paris en 1860*, *Ghél ou une colonie d'Algériens* (1860), *Histoire de l'émigration européenne, asiatique, et africaine au XIX siècle* (1862, probably his masterpiece, and the work by which he gained the prize offered by the Académie des sciences morales in 1860), *Les colonies et la politique coloniale de la France* (1864), *Des rapports entre la géographie et l'économie politiques* (1864), *Mémoire sur Ant de Mont Chrétien, auteur du premier traité d'économie politique* (1868), *Notre Pays* (1869), *Notre planète* (1869). See Levasseur's "Notice sur J. Duval" in *Bulletin de la Soc de Géogr.*, 1876.

DUVERGIER DE HAURANNE, JEAN (1581–1643), abbé of St Cyran, a celebrated French theologian, was born at Bayonne in 1581. He studied theology at the university of Louvain, where he formed an intimate friendship with Jansen, who was his fellow student. After quitting Louvain he went to Paris, where his intimacy with Jansen continued, and with him he pursued with great ardour the study of the fathers. Leaving Paris in 1611, they continued the same studies at Bayonne, where Duvergier received the canonry of the cathedral. When Jansen left Bayonne, Duvergier returned again to Paris, and shortly after his arrival there his inflexible and ascetic character secured for him the esteem of the bishop of Poitiers, who gave him a canonry, and in 1620 made him abbé of St Cyran. He established in the monastery the order of St Benoît in all its rigour; but his zeal for reform was so great that it awakened opposition, and he found it expedient to quit his diocese and return to Paris. Here he formed a connection with the influential Arnauld family, and along with Angelique Arnauld, directress of the convent of Port Royal, he completely reformed that institution. His rigorous asceticism acquiring for him great ascendancy over feminine minds, his fame and influence increased with great rapidity, and he soon began to number among his disciples members of the highest classes of society, and to have as his personal friends some of the chief dignitaries of church and state. Soon, however, his enemies came to be as numerous as his friends. His rigid and domineering disposition began to alienate from him many of his disciples; and, taking a leading part in the Jansenist controversy, he excited against himself the peculiar animosity of the Jesuits. At last his views came to be suspected by Richelieu, and he was arrested and thrown into prison at Vincennes, 14th March 1638. No evidence could be obtained from his papers sufficient to criminate him, but to limit his influence he was retained in durance at Vincennes—where, however, he was able to keep up intercourse with his penitents and disciples. On the death of Richelieu he regained his liberty, and resumed his religious duties and his war with the Jesuits with the same energy as before; but he enjoyed only six months of freedom, dying from a stroke of apoplexy, 10th October 1643.

DWĀRAKĀ, DWĀRKA, or JIGAT, a town of British India, in Guzerat, near the extremity of the peninsula of Kattywar, in 22° 15' N. lat. and 69° 1' E. long. It is surrounded by a wall, has about 2000 permanent inhabitants, and trades in chalk. As the birthplace and residence of Krishna, it is the most sacred spot in this part of India, and its principal temple is visited annually by many thousand pilgrims. The approach from the sea is by a fine flight of stone steps, and the great pyramid rises to a height of 140 feet. Dwārakā is of course frequently mentioned in the *Mahābhārata*. It was occupied by the British in 1816.

DWARF (Saxon *duerg*, *duerorg*; German, *Zwerge*), a term applied to men, animals, and plants that fail to reach even the mediocrity of growth natural to their respective classes. It is also otherwise applied. In France, for instance, a yolkless egg is termed “un œuf nain,” or dwarf egg; and an imitation of fine English cloth is called “nain Londrin,” technically “London dwarf.”

The *nani*s or *pumilo* of the Romans might be a dwarf by nature or a person dwarfed by cruel art. In the former case, his lack of height found compensation in increased strength, as exemplified in the line by Propertius. “*Nanus et ipse suos breviter concretus in artus.*” &c.; in the latter, where growth had been early suppressed by the dealers who manufactured monstrosities for fashionable people in Rome, weakness bred contempt. The *nani*s, or, if he were more than usually diminutive, the *nani*um, was exposed to

application of the proverb, “*nanus cum sis, cede,*” equivalent to “little people must not be in our way.”

Various have been the recipes for dwarfing children from birth. The most effective, according to report, was anointing the back bone with the grease of moles, bats, and dormice. It is also said that pups were dwarfed by frequently washing their feet and backbone, the consequent drying and hardening of those parts hindered, it was alleged, their extension. In England, the growth of boys intended for riders in horse-races is kept down to some extent by the weakening process of “sweating.”

There is a familiar story of a partnership entered into between a dwarf and a giant. The dwarf had the intellect, the giant had the strength; the result of this limited liability was that the giant received all the blows, and the dwarf all the profits. The partnership was consequently broken up. A fact, of which we are reminded by this fiction, occurred in Austria in the 17th century. To please the caprice of an empress, all the giants and dwarfs in the empire were brought together to Vienna, and were lodged in one building. The dwarfs were told they had nothing to fear from the giants; but the latter were soon put in bodily fear of the dwarfs, who made the life of their stupendous companions unbearable by teasing them, molesting them, tripping them up, and un-crupulously robbing them. The giants, with tears as big as pearls in their eyes, prayed the authorities to relieve them from the persecution of their tiny enemies, and the prayer was granted. At a later period, another German princess promoted marriages among dwarfs, but without succeeding in the object she had in view. When Lady Mary Wortley Montague was in Germany, in the last century, she found that a dwarf was a necessary appendage to every noble family. At that time English ladies kept monkeys. The imperial dwarfs at the Viennese court were described by Lady Mary as “as ugly as devils” and “bedaubed with diamonds.” They had succeeded the court fools, and exercised some part of the more ancient office. Absolute princes could not stoop to familiar discourse with mankind of less degree. Therefore did they hold dwarfs to be outside humanity, made intimate associates of them, and allowed them an unrestrained freedom of speech, by the exercise of which the dwarfs imparted to their masters wholesome truths which on the lips of ordinary men would have been treason. One of the kings of Denmark is said to have made a prime-minister of his dwarf, in order to get at rough truths which a minister of ordinary stature would have been afraid to utter.

It could not have been for this reason that Stanislas, ex-king of Poland and duke of Lorraine, was so attached to his dwarf, Nicholas Ferry, otherwise known as “Bébé,” for this dwarf was weak in mind and body. Bébé was one of three dwarf children of peasant parents in the Vosges. He was 3 feet in height, and his fame has not died out at Nancy and the department of the Meurthe. At his death in 1764 he was in his twenty-third year; and, among the fine phrases of which his epitaph is composed, the world is still assured that Bébé was “*chéri du nouvel Antonin.*”

But Bébé was not so remarkable a dwarf as Richebourg, who died in Paris in 1838, at the age of ninety. He was only 23 inches in height. In his childhood he was a servant (without especial duty) in the Orleans family. In later years, Richebourg was their pensioner. He is said to have been put to strange use in the Revolutionary period,—passing in and out of Paris as an infant in a nurse’s arms, but with despatches, dangerous to carry, in the little man’s baby wrappings! At present, on the Continent, Russia and Turkey alone have a common sympathy for dwarfs. At the court of the sultan, should the dwarf, besides being of elfish height, be deaf, dumb, and qualified to hold a place

among the official eunuchs, the poor creature is accounted as a priceless treasure

The early history of British dwarfs is less studded with wonders than the record of dwarfs of the classical times. Britain has nothing to compare with Philetas of Cos, the little tutor of Ptolemy Philadelphus. Ælian would have us believe that Philetas was so light as well as diminutive that he wore leaden weights in his pockets to prevent his being blown away. Nor does any British chronicle register such minute marvels as the couple of dwarfs possessed by Julia, the niece of Augustus, namely, Coropas and Julia's little handmaid Andromeda. The height of both was 2 feet 4 inches. This, however, was little less than the stature of the Aztec dwarfs who were exhibited (and were publicly married) in London some twenty years ago. It is not that British annals or tradition can be said to be entirely silent on dwarfs as wonderful as Ælian's. The earliest, known by the now generic name of "Tom Thumb," presents himself to us in the ancient ballad which begins with the record that "In Arthur's court Tom Thumb did live." Antiquaries, on probably no better foundation, are content with placing the proto-Thumb at the court of King Edgar. It is certain that such shrunken samples of humanity figured in great festivals, as we see their foreign brethren in some of the pictures of the Italian and Spanish masters. The first English dwarf of whom there is authentic history was presented to Queen Henrietta by the duchess of Buckingham, as he stepped out of a pie at a banquet. This was Jeffery Hudson of Rutlandshire. He was born in 1619, and was only 1½ feet high from his eighth year to his thirtieth, after which he grew to the stature of 3 feet 9 inches, and never went beyond it. His life was not made up of court pleasures. He fought two duels,—one with a turkey-cock, a battle recorded by Davenant, and a second with Mr Crofts, who came to the meeting with a squirt, but who in the more serious encounter which ensued was shot dead by little Hudson, who fired from horseback, the saddle putting him on a level with his lofty but unlucky antagonist. Twice was Jeffery made prisoner,—once by the Dunkirkers as he was returning from France, whither he had been on homely business for the queen, the second time was when he fell into the hands of Barbary corsairs. In each case his liberty was soon purchased. But Jeffery died in prison, nevertheless. He was accused of participation in the "Popish Plot," and in 1682 this dwarf died in the Gate House, in the sixty-third year of his age.

Contemporary with Hudson were the two dwarfs of Henrietta Maria, Gibson and his wife Anne. They were married by the queen's wish, and the two together measured only a couple of inches over 7 feet. They had nine children, five of whom, who lived, were of ordinary stature. Edmund Waller celebrated the nuptials, Evelyn designated the husband as the "compendium of a man," and Lely painted them hand in hand. Gibson was miniature painter to Charles I., and drawing-master to the daughters of James II., the Princesses Mary and Anne, when they were children. This Cumberland pigmy, who began his career as a page, first in a "gentle," next in the royal family, died in 1690, in his seventy-fifth year, and is buried in St Paul's, Covent Garden. The last court dwarf in England was Coppernun, a lively little imp in the service of the Princess (Augusta) of Wales, the mother of George III. The last dwarf retainer in a gentleman's family was the one kept by Mr Beckford, the author of *Vathek* and builder of Fonthill. He was rather too big to be flung from one guest to another, as used to be done at after-dinner tables, when the wine had got the better of common sense.

Of exhibited dwarfs in England, the most celebrated was the Pole, Borulwaski, whom fashion patronized in the last

century and forgot in the present one. He was then a yard and 3 inches in height, and he had a sister shorter than himself by the head and shoulders. Borulwaski was a handsome man, a wit, and something of a scholar. He travelled over all Europe, and he—born in the reign of George II., 1739—died in his well-earned retirement near Durham, in the reign of Victoria, 1837. Borulwaski, buried in the above-named city, lies by the side of the Falstaffian Stephen Kemble. The companionship reminds one of that of the dwarf skeleton of Jonathan Wild by the side of that of the Irish Giant, at the Royal College of Surgeons, London.

In the year in which Borulwaski died, 1837, the line of publicly exhibited dwarfs was continued by the birth of the existing American pigmy, Charles Stratton, better known as "General Tom Thumb." In 1844 he appeared in England, where his grace, vivacity, and good humour made him popular, from the royal family to the general public, before whom he acted at the Lyceum Theatre. He also made his appearance on the stage in Paris. After extensive travel in both hemispheres, he again visited England in 1857, but the dwarf man, despite many personal and intellectual qualities, was less attractive than the dwarf boy. In the year 1863 the "General" married the very minute American lady, Lavinia Warren (born in 1842), with whom he has seen many lands, and they are now enjoying honourable retirement in their own. (J. DO.)

DWIGHT, TIMOTHY (1752–1817), an eminent American divine, was born at Northampton, Massachusetts, 14th May 1752. His father, though educated at Yale College, was a merchant, and his mother the third daughter of Jonathan Edwards. His mother began to instruct him almost as soon as he was able to speak, and it is said that he learned the alphabet at a single lesson, and before he was four years old was able to read the Bible. In 1765 he entered Yale College, and received his B.A. degree in 1769, shortly after which he went to take charge of a grammar school at Newhaven, where he remained two years. In September 1771 he was appointed tutor in Yale College, where he distinguished himself by the skill with which he taught the higher mathematics. In the same year he began an epic poem entitled the *Conquest of Canaan*, which was published in 1785. He received his degree of M.A. in 1772, and afterwards pursued his studies with the view of adopting law as his profession, but, changing his intention, was licensed as a preacher of the gospel in 1777, and accepted the office of chaplain to the forces, which post he held for some time. In 1783 he was ordained minister of Greenfield in Connecticut, when he opened an academy which speedily acquired a very high reputation, and attracted scholars from all parts of the Union. He received the degree of D.D. from Princeton College in 1785, and that of LL.D. from New Jersey in 1810. In 1795 he was elected president of Yale College, and by his judicious management restored that institution to the high place from which it had fallen before his appointment. He died at Philadelphia on the 11th January 1817. Dr Dwight was the author of a considerable number of essays and sermons; and his *Theology Explained and Defended in a series of Sermons* was published in 5 vols., with a life of the author, in 1818. Two additional volumes of sermons were published in 1827, and had an extensive circulation both in the United States and in England.

DWINA, a name common to two important rivers of European Russia.

(1.) The NORTHERN DWINA, or *Dvina Sievernaya*, belongs to the basin of the White Sea, and is formed by the junction of the Sukhona and the Yuk, which, rising the former in the south-east and the latter in the south-west of the government of Vologda, meet in the neighbourhood

of Veliki Ustyug, at a height of 300 feet above the sea, in $60^{\circ} 46'$ N. lat. and $46^{\circ} 20'$ E. long. From its mouth, in the Gulf of Archangel, the distance to the confluence of the co tributary streams is about 400 miles, and to the source of the Sukhona 750 miles. The drainage area is estimated at from 140,000 to 145,000 square miles. Except at the rapids the current of the Dwina is comparatively slow, as the average fall per mile is only 9 inches. Till its union with the Vichegda, a river which exceeds it in volume, it flows for the most part in a single, well-defined, and permanent channel; but below that point it often breaks up into several branches, and not unfrequently alters its course. In the neighbourhood of Archangel it divides into three distinct arms, which form a regular delta; but of these that of Berezhoff alone is navigable for seafaring vessels, and even it is crossed by a bar at the mouth with not more than $14\frac{1}{2}$ or $15\frac{1}{2}$ feet of water at full tide. Above the confluence of the Vichegda the breadth is about 1750 feet, below that point it widens out to 3500, and near Archangel it attains more than three times that measure. The river affords a valuable means of inland navigation. From Vologda to Archangel the ordinary passage requires from 10 to 12 days, and the return journey from 6 to 8 weeks. The channel is free from ice for about 174 days in the year.

II. The SOUTHERN DWINA, or *Dvina Zapadnaya*, in German *Düna*, belongs to the Baltic basin, and takes its rise in a small lake about 800 feet above the level of the sea, in the government of Tver, not far from the sources of the Volga and the Dnieper. In its whole course of about 600 miles it waters the seven governments of Tver, Pskoff, Vitebsk, Mogileff, Vilna, Curland, and Livonia; and it is calculated that it drains an area of about 65,000 square miles. From Düna to Riga, a distance of 204 miles, there is altogether a fall of 295 feet, of which 105 are in the $46\frac{1}{2}$ miles from Jakobstadt to Friedrichstadt. In the lower part of its course the river attains an ordinary depth of 30 feet, and an average breadth of 1400 feet; but during the spring flood it sometimes rises 14 feet above its usual level, and extends its waters for about a mile. The inundation lasts at Riga from two to ten days. Near the mouth the river is usually free from ice 245 days in the year, and in the government of Vitebsk for 229. It is navigable from the confluence of the Mezha downwards, but the number of rapids and shallows greatly diminishes its value. No fewer than 62 of the former are counted below Jakobstadt, and among these are some of the most dangerous of all. The passage to Riga from Velish usually takes thirteen days, from Disna seven, from Düna four, from Friedrichstadt one. Navigation can also be carried on by the following tributaries of the Dwina—the Toropa, the Usviat, the Mezha and Obshei, the Kaspha, the Ulla, and the Bolder-aa. By Ptolemy and Marcan of Heraclea the river is mentioned as the Rhubon or Rhudon; at a later date it is called the Khezir or Turunt, and till the present day has the name of Polot among the White Russians. The modern designation is said to be due to the Schleswig and Bremen sailors, who were struck by the sandstone hills at the mouth of the river.

DYCE, ALEXANDER, (1798–1869), a distinguished dramatic editor and literary historian, was born at Edinburgh on the 30th June 1798, and, after receiving his early education at the High School of his native city, became a student at Exeter College, Oxford, where he graduated as B.A. Having adopted the clerical profession, he officiated as curate at Lantegloss, in Cornwall, and subsequently at Nayland, in Suffolk; and, in 1827, he settled in London. His first books were *Select Translations from Quintus Smyrnæus*, an edition of Collins, and *Specimens of British Poetesses*. He issued annotated editions of George

Peele, Robert Greene, John Webster, Thomas Middleton, and Beaumont and Fletcher, with lives of the authors and much illustrative matter. He completed an edition of Shirley left unfinished by Gifford, and contributed biographies of Shakespeare, Pope, Akenside, and Beattie to Pickering's *Aldine Poets*. He has also edited several of Bentley's works, and *Specimens of British Sonnets*; and his carefully revised edition of John Skelton, which appeared in 1843, did much to revive interest in that trenchant satirist. In 1857 his edition of Shakespeare was published by Moxon; and the second edition, a great improvement on the old one, was issued by Chapman and Hall in 1866. Dyce's interest in Shakespeare manifested itself further in such works as *Remarks on Collier's and Knight's Editions of Shakespeare*, *A Few Notes on Shakespeare*, and *Structures on Collier's new Edition of Shakespeare*. He was intimately connected with several literary societies, and undertook the publication of Kempe's *Nine Days' Wonder* for the Camden Society, and the old plays of *Timon* and *Sir Thomas More* were published by him for the Shakespeare Society. He was associated with Halliwell, Collier, and Wright as one of the founders of the Percy Society, which aims at publishing old English poetry. Dyce also issued *Recollections of the Table-Talk of Samuel Rogers*, which has been several times reprinted both in Britain and in the United States. The editions of the dramatists already mentioned were re-issued with many improvements. Dyce died on the 15th May 1869. His reputation rests on his contributions to English literary biography, and on the untiring industry, abundant learning, and admirable critical acumen displayed in his editions of the old English poets. His wide reading in Elizabethan literature enabled him to explain much that was formerly obscure in Shakespeare, while his sound judgment was a sure check to anything like extravagance in emendation. His labours resulted in the best text of Shakespeare we possess. While preserving all that is valuable in former editions, Dyce has added much fresh matter. The *Glossary*, which consists of a large volume of 500 pages, is the most exhaustive that has appeared. Not only rare words are explained, but common words when employed with an unusual meaning, phrases, proverbs, old customs, and difficult allusions. The book is, therefore, an important contribution to philology and to the history of the English language, as well as to the elucidation of the text. The mere number of words in Dyce's *Glossary* shows a great advance in comprehensiveness. It is calculated that the *Globe Glossary* has about 2000 words, and Staunton's 2500, while Dyce's has upwards of 5000. The meanings of the words, as used by the poet, are accurately given, and are illustrated by literary quotation and linguistic comment. Altogether Dyce's Shakespeare is likely long to remain the standard edition of our English dramatist.

DYCE, WILLIAM (1806–1864), a distinguished painter, was born in Aberdeen, where his father, a fellow of the Royal Society, was a physician of some repute. He attended Marischal College, took the degree of M.A. at sixteen years of age, and was destined for one of the learned professions. Showing a turn for design instead, he studied in the school of the Royal Scottish Academy in Edinburgh, then as a probationer (not a full student) in the Royal Academy of London, and thence, in 1825, proceeded to Rome, where he spent nine months. He returned to Aberdeen in 1826, and painted several pictures, one of these, Bacchus nursed by the Nymphs of Nysa, was exhibited in 1827. In the autumn of that year he went back to Italy, showing from the first a strong sympathy with the earlier masters of the Florentine and allied schools. A *Virgin and Child* which he painted in Rome in 1828 was much noticed by Overbeck and other foreign artists. In 1829 Dyce settled in

Edinburgh, taking at once a good rank in his profession, and showing considerable versatility in subject-matter. Portrait-painting for some years occupied much of his time; and he was particularly prized for likenesses of ladies and children. In February 1837 he was appointed master of the school of design of the Board of Manufactures, Edinburgh. In the same year he published a pamphlet on the management of schools of this description, which led to his transfer from Edinburgh, after eighteen months' service there, to London, as superintendent and secretary of the then recently established school of design at Somerset House. Mr J. R. Herbert was head-master about the same time. Dyce was sent by the Board of Trade to the Continent to examine the organization of foreign schools, and a report which he eventually printed, 1840, led to a remodelling of the London establishment. In 1842 he was made a member of the council and inspector of provincial schools, a post which he resigned in 1844. In this latter year, being appointed professor of fine art in King's College, London, he delivered a noticeable lecture, *The Theory of the Fine Arts*. In 1835 he had been elected an associate of the Royal Scottish Academy; this honour he relinquished upon settling in London, and he was then made an honorary R.S.A. In 1844 he became an associate, in 1848 a full member, of the London Royal Academy, he also was elected a member of the Academy of Arts in Philadelphia. He was active in the deliberations of the Royal Academy, and it is said that his tongue was the dread of the urbane President, Sir Charles Eastlake, for Dyce was keen in speech as in visage; it was on his proposal that the class of retired Academicians was established. In January 1850 Dyce married Jane, daughter of Mr James Brand, of Bedford Hill, Surrey. He died of a cancerous disease in his house at Streatham on 14th February 1864, leaving two sons and two daughters.

Such is a brief outline of the honourable and prosperous career of one of the most learned and accomplished of British painters—one of the highest in aim, and most consistently self-respecting in workmanship. His finest productions, the frescoes in the Queen's Robing-room in the Houses of Parliament, may rightly be called great, and an honour to the country and time which produced them; these frescoes, and the water-glass paintings of Maclise in the same building, would find few rivals in contemporary Continental labours. Generally, however, there is in Dyce's work more of earnestness, right conception, and grave, sensitive, but rather restricted powers of realization, than of authentic greatness. He has elevation, draughtsmanship, expression, and on occasion fine colour; along with all these, a certain leaning on precedent, and castigated semi-conventionalized type of form and treatment, which bespeak rather the scholarly than the originating mind in art. The following are among his principal or most interesting works (oil pictures, unless otherwise stated). 1829. *The Daughters of Jethro defended by Moses*, Puck. 1830. *The Golden Age*, the Infant Hercules strangling the Serpents (now in the National Gallery, Edinburgh), Christ crowned with Thorns. 1835. *A Dead Christ* (large lunette altar-piece). 1836. *The Descent of Venus*, from Ben Jonson's "Triumph of Love," *The Judgment of Solomon*, prize cartoon in tempera for tapestry (National Gallery, Edinburgh). 1837. *Francesca da Rimini* (National Gallery, Edinburgh). 1838, and again 1846. *The Madonna and Child*. 1839. *Dunstan separating Edwy and Elgiva*. 1844. *Joash shooting the Arrow of Deliverance* (the finest perhaps of the oil-paintings). 1850. *The Meeting of Jacob and Rachel*. 1851. *King Lear and the Fool in the Storm*. 1855. *Christabel*. 1857. *Titian's first Essay in Colouring*. 1859. *The Good Shepherd*. 1860. *St John bringing Home his Adopted Mother*,

Pegwell Bay (a coast scene of remarkably minute detail, showing the painter's partial adhesion to the so-called "pre-Raphaelite" movement of that time). 1861. *George Herbert at Bemerton*. Dyce executed some excellent cartoons for stained glass:—that for the choristers' window, Ely Cathedral, and that for a vast window at Alnwick in memory of a duke of Northumberland; the design of Paul rejected by the Jews, now at South Kensington, belongs to the latter. In fresco-painting his first work appears to have been the Consecration of Archbishop Parker, painted in Lambeth Palace. In one of the Westminster Hall competitions for the decoration of the Houses of Parliament, he displayed two heads from this composition; and it is related that the great German fresco-painter Cornelius, who had come over to England to give advice, with a prospect of himself taking the chief direction of the pictorial scheme, told the Prince Consort frankly that the English ought not to be asking for him, when they had such a painter of their own as Mr Dyce. The cartoon by Dyce of the Baptism of Ethelbert was approved and commissioned for the House of Lords, and is the first of the works done there, 1846, in fresco. In 1848 he began his great frescoes in the Robing room—subjects from the legend of King Arthur, exhibiting chivalric virtue. The whole room was to have been finished in eight years; but ill-health and other vexations trammelled the artist, and the series remains uncompleted. The largest picture figures Hospitality, the admission of Sir Tristram into the fellowship of the Round Table. Then follow—Religion, the Vision of Sir Galahad and his Companions, Generosity, Arthur unhorsed, and spared by the Victor, Courtesy, Sir Tristram harping to la Belle Yseult; Mercy, Sir Gawaine's Vow. The frescoes of sacred subjects in All Saints' Church, Margaret Street, London; of Comus, in the summer-house of Buckingham Palace; and of Neptune and Britannia, at Osborne House, are also by this painter.

Dyce was an elegant scholar in more ways than one. In 1828 he obtained the Blackwell prize at Aberdeen for an essay on animal magnetism. In 1813-4 he published an edition of the Book of Common Prayer, with a dissertation on Gregorian music, and its adaptation to English words. He founded the Motett Society, for revival of ancient church-music, was a fine organist, and composed a "non nobis" which has appropriately been sung at Royal Academy banquets. His last considerable writing relating to his own art was published in 1853, *The National Gallery: its Formation and Management*. (W. M. R.)

DYEING is the art of colouring in a permanent manner porous or absorbent substances by impregnating them with colouring bodies. Most vegetable and animal bodies are porous or absorbent, and can be dyed; some minerals also, such as marble, can absorb liquid colouring matters; but the term dyeing is usually confined to the colouring of textile fibrous materials by penetration. The superficial application of pigments to tissues by means of adhesive vehicles, such as oil or albumen, as in painting or in some kinds of calico-printing, is not considered as a case of dyeing, because the colouring bodies so applied do not penetrate the fibre, and are not intimately incorporated with it. The mere saturation of textile fibre with a solution of some coloured body and subsequent drying do not constitute a case of dyeing, unless the colour becomes in so far permanently attached to the fibre that it cannot be washed out again by the solvent employed or by common water. In the present article dyeing will be considered only with relation to the vegetable and animal fibrous substances which are commonly used in clothing or furniture,—the less important arts of dyeing feathers, skins, ivory, wood, marble, &c., being left over for treatment under other headings.

HISTORICAL SKETCH.

That dyeing was practised in the most ancient times is abundantly proved by the frequent mention of dyed colours in the oldest extant writings, that it was not a common art seems apparent from the uses to which coloured garments were devoted, and the distinction which they conferred upon the wearers. It is probable that such definite and bright colours as the "blue, and purple, and scarlet" mentioned several times in the book of Exodus, as well as the Tyrian purple so often referred to by Roman writers of the Augustan age, were so costly as not to be available for general and common use. Pliny is the only one of the older writers from whom we might have expected some account of the processes of dyeing employed at his time; but, except a reference to two or three tinctorial substances, and a description of a process of obtaining several colours by one dyeing operation, which he saw practised in Egypt (see CALICO-PRINTING, vol. iv. p. 684), there is nothing detailed in his writings,—he in fact formally excuses himself from entering upon the subject as one not worthy of his attention. The Tyrian purple is the only dye treated of at some length in Pliny and contemporary authors; its discovery and employment gave wealth and prosperity to Tyre and Sidon more than 1000 years B.C. In the days of the Roman conquests in the East it was reserved under penal statutes for imperial use; its production then declined, and eventually both the material and the art of using it were lost. From Pliny's description, modern investigators were enabled to rediscover the shell-fish which yielded the dye, but the colours furnished by it were neither so bright nor so permanent as those obtainable from much less costly dyeing materials; and there is reason to conclude that the most brilliantly tinted garments of an Egyptian priest of Isis or Osiris, or the mantle of a Roman emperor, were poor and dull in hue compared with those within reach of a domestic servant of the present time.

From many independent sources—Homer, Strabo, Herodotus, &c.,—it is clearly shown that the manufacture of coloured tissues was carried on by the Oriental nations. A knowledge of the art spread slowly westward, but there are few records of its existence to be found from the time of Pliny to about the 13th century. It would appear that the Jews held the secret or the monopoly of the dyeing art during this long period. According to Mrs Merrifield, Benjamin of Tudela relates that when he visited Jerusalem between 1160 and 1173 he found only 200 Jews resident in that city, and these were all engaged in wool-dyeing, which trade was entirely in their hands. Beckmann shows that at the same epoch the art of dyeing in Italy was principally carried on by Israelites. It is in Sicily that we can first distinctly discern the practice of dyeing in Europe, afterwards the Italians generally practised it; and in the 13th century dyers formed important guilds in Florence, Venice, and other cities. It is not to be supposed that the art of dyeing was ever completely lost; the records of particular seats of the art only indicate that at such places some special excellence had been acquired which gave them a higher reputation than was enjoyed by others. The domestic records of all modern nations speak of dyers and dyed cloths. Among the ancient laws of Ireland are some which lay down the number of colours that may be employed in the dress of various classes of society, the monarch alone being permitted to wear seven colours; from which it may be inferred that if the Irish at a very early period were not dyers, they at least had variously dyed garments. Similar facts can be adduced of all countries that possess an early literature.

From the perishable nature of textile substances and their comparatively small intrinsic value, very few ancient

examples of the dyer's art have been preserved. We have, however, one account of a cloth containing dyed yarn which may have been in the dyer's hands in Egypt 1000 years before the Christian era; and we have still in good preservation ecclesiastical vestments containing dyed silks which are certainly 600 to 700 years old. The late Mr Thomson of Clitheroe examined numerous mummy cloths, some of which had a border of blue and fawn-colour made by coloured threads introduced into the loom. The blue, upon examination, was proved to have been dyed with indigo; other specimens of mummy cloth of a reddish colour appeared to have been dyed with safflower, though this colouring matter could not be recognized with the same certainty as indigo. Dr Rock, in his catalogue of the textile fabrics in the South Kensington Museum, attributes many of the church vestments there preserved to the 12th and 13th centuries, and in these can be seen silks of all the colours known to dyers up to the middle of the present century, which, though in most cases changed and faded, still present sufficient evidence that dyeing, upon this material at least, was successfully practised in the Middle Ages. It is interesting further to note that in inventories of vestments of the 13th century the silks in the vestments are often designated by their colours, as in a chasuble at St Paul's, London, 1295, which is set down as "*purpureo aliquid sanguineo*," of a purple inclining to blood red. This, as Dr Rock says, is intelligible; but other definitions are not, as "*pannus Tarsici coloris*," a Tarsus-coloured cloth; it can only be conjectured that it was a purple dyed at Tarsus, and something like the Tyrian purple; sky-blue silk is named "*indicus*," probably because it was dyed with indigo.

The earliest account of the processes and materials used by dyers is to be found in a collection of manuscripts in the French National Library, No 6741, known as the manuscripts of Jehan le Begne. These mostly refer to the art of painting and the making of artists' colours and the modes of applying them, but some describe the preparation and use of dyes. The most interesting of these manuscripts is by Jehan Alcherius (Le Begne was only the copier or compiler), which from internal evidence cannot be dated later than the year 1410, and some parts of which refer to a period at least thirty years earlier. Among the colouring matters and mordants there mentioned we find iron (the dust or mud from grindstones on which knives are ground) dissolved in vinegar and mixed with alum, green copperas, and gall nuts prescribed as a black colour; and methods are given for the use of Brazil wood, litmus, indigo, in conjunction with lime and honey, verdigris, alkalis, oxide of tin, kermes, &c., much in the same way as those employed four centuries later by dyers and calico-printers. There are also eleven receipts for preparing colours, for painting on cloth to imitate tapestry,—examples of which (*toiles peintes*) of the 15th century were exhibited in Paris in 1876. Curiously enough, a certain Fleming named Theodore in 1410 brought these receipts to Alcherius from London, where they were in regular use. They are all chemical dyes, and seem to be the prototypes of the same class of colours employed long subsequently by calico-printers in England and other countries.

The first printed account of dyeing processes was an Italian work. It is referred to under the title *Mariegola dell' arte dei Tintori*, published at Venice in 1429. The writer has never seen a copy of this work, nor does it appear that any exists in the chief libraries of Europe; an enlarged edition was published in 1510. In 1548 Rosetti wrote an account of dyeing, which was also published at Venice. Copies of this are not very scarce; it is the only one of these early books which is actually known. The so-called Bolognese manuscript translated in Merrifield's

Ancient Practice of Painting, is preserved in the convent of St Salvatore at Bologna, and is said not to be of later date than the middle of the 15th century—that is, about 100 years anterior to the date of Rosetti's work. In this manuscript, in addition to the materials enumerated by Alechierus, mention is made of wood and methods of making indigo from it, of indigo imported from India, called *bagadon* and *bagadel*, of sumach, gall nuts, and lac, of the berries of buckthorn, similar to the Avignon or Persian berries, to be used for yellow, and of Brazil wood or *vermilion*, sandal wood, and madder for red, and archil for purple. The use of nitric acid to give a yellow colour to silk, and of alum for preparing and mordanting that material, and the subsequent dyeing of it by Brazil wood, are also clearly pointed out. The receipt No 362 of this manuscript is of interest as showing that the Italian dyers early possessed the method of dissolving indigo by means of the action of honey and quicklime upon it, and used the solution for the blue required in dyeing silk green.

It is very clear, then, from these accounts, and from numerous existing samples of coloured stuffs, that dyeing was well understood in Europe in the 15th century, and that the materials at the command of the dyer were sufficiently numerous and varied to enable him to produce all desired shades of colour. The improvements which took place in the dyeing art from this time until the commencement of the present era of artificial colouring matters were no doubt important in detail, but not very striking in principle.

The discovery of America was soon followed by the introduction of cochineal (see vol. vi. p. 97), but this did not enable the dyer to produce any new colours, since it differed from the ancient kermes, frequently called *grana* or grains, only in being ten or twelve times as rich in colouring matter. Logwood or Campeachy was also an introduction from the New World, and greatly enlarged the power of the dyer, though, from the looseness of the colours it yielded, it brought his art into some disrepute; it was in many respects a new colouring matter, but eventually settled down as the principal ingredient in the common black dye. In mordants, the discovery in Holland in the 17th century of the use of solutions of tin in acid, especially for the scarlet dye with cochineal, was one of the greatest utility. The gradual introduction of the acetates of aluminium and iron to replace the respective sulphates was of more importance to calico-printing than dyeing proper. At the close of the last century Dr Baucroft discovered and introduced quercitron bark from America for dyeing yellows, and this, from its superior richness and less cost, displaced other materials used for that purpose. Of the natural dyes introduced in the present century probably the most important is catechu. The discovery of the use of bichromate of potash as a mordant for woollen goods belongs to the latter half of this century, and has been of the highest benefit to the dyer. We shall not speak in detail of a number of dye-stuffs used by dyers of the present day, which were probably unknown to their predecessors, because most of them are only varieties of what have been long employed. Such, for example, are valonia, divi-divi, and myrobalans, which have no properties different from galls or sumach, and the different red woods, which are merely varieties of the anciently known Brazil woods.

Artificial Colouring Matters—In the year 1858 commenced the discovery and application of a series of artificial colouring matters, which have created a distinct era in the history of dyeing. Up to that date the colouring matters used in dyeing were either the spontaneous productions of nature or simple preparations of the same. An exception, however, must be made to this statement in respect of Prussian blue and the so-called sulphate of indigo, which

have been largely used as colours in dyeing since the middle of the last century, and are as truly products of art as any of the modern creations of chemistry. The purple of murexide had only a brief existence as a dye. Mr Perkin was the first to practically produce a dyeing material from aniline, the well-known mauve or purple shade so much in vogue for several years, for a history of which see vol. ii. p. 48 of the present work. Other discoveries rapidly followed, and in the course of a few years it may be said that a hundred patents were taken out for methods of making artificial colouring matters from aniline and its homologues; these alkaloid bases, under the transforming hands of chemists, supplied the dyer with every shade and hue which could be desired. Up to 1869 the artificial colours were of one general family, and had many characters in common, they were very brilliant, very easily applied on fibre of animal origin (silk and wool), required no mordant, and for the most part were very loose and unstable. Imitating more or less closely the colours obtained on tissues from natural colouring matters, they had no similarity of chemical composition, and were in every other respect fundamentally different from them. In 1868 two German chemists, Graebe and Liebermann, by means of a severe synthetical investigation, succeeded in transforming anthracene into alizarin, the latter being identical in chemical composition as well as tinctorial properties with the colouring matter of madder, one of the most anciently known and most valuable of all natural dye-stuffs (see vol. i. p. 577). This was the first instance in which chemistry had produced one of the old and well-known colours of the dyer; in a short time after its discovery it was made practically available for the trade, and has at this date (1877) almost entirely driven from the market the native product,—accomplishing a revolution which has no parallel in the history of colouring matters, and which is one of the most signal triumphs of modern chemistry. Other natural colouring matters have since then been produced by art, such as indigo and archil, but from some difficulties in their manufacture they have not yet become commercially available.

Mechanical Improvements—In the art of dyeing, steam power has proved no less serviceable than in other important industries. Its applications are not further alluded to in this article, but in the article upon CALICO-PRINTING (vol. iv. p. 684) some illustrations of modern machinery may be seen.

GENERAL PRINCIPLES OF DYING.

Although many eminent chemists have worked and written upon the subject, there still remains much difference of opinion as to what actually takes place in dyeing operations. The following general account of the chief cases of dyeing will illustrate the principal methods in use, and serve as an introduction to a description of actual processes practised in dye-houses. Afterwards, the attempts made to construct a general theory will be briefly considered. The simplest cases of dyeing are those in which only two substances are employed—the fibre to be dyed and the colouring matter—and where the process of dyeing consists in nothing more than leaving the two materials in contact for a certain time at a convenient temperature. Of natural colouring matters few can be practically used in this simple way without some previous chemical treatment. The artificial colouring matters from aniline, however, illustrate this kind of dyeing very well. To obtain the finest shades of mauve, magenta, purple, and numerous other colours upon wool and silk fibre the whole process consists in placing the material in a solution of the requisite colour and of sufficient quantity to give the desired shade, it absorbs the

colour, becoming dyed, while the solution is rendered nearly colourless. During the process the fibrous material is kept in a constant state of movement, so that the dye solution shall have equal access to all portions, the temperature employed and time allowed being regulated according to the necessities of the case. The colour absorbed by the fibre has entered into an intimate state of combination with it, since it cannot be washed out again; a true dyeing has taken place. Besides the aniline colours, the older artificial dyes—sulphindigotic acid, picric acid, and one or two others—have the same property of combining directly with wool and silk.

There are other cases of dyeing closely resembling the foregoing, in which the resulting dyed stuff may be considered as being a binary compound of fibre and colouring matter, but in which the methods of application are less simple. These may be taken generally as consisting in the use of materials or processes which bring a previously insoluble colouring matter into a soluble state; thus the pink colours of safflower are obtained by the action of an alkali; and the dyes yielded by archil, arnatto, and indigo are also the result of the action of solvents. It is possible that during the process of solution important internal changes may take place in the composition of the above dyes, but if so, they are only of a temporary nature, for there is no reason to suppose that the colouring matter attached to the fibre differs in chemical composition from that which is free.

With regard to nearly all other colouring matters, the above simple processes are quite powerless to induce a permanent combination with the fibre. Let wool or silk be immersed at boiling temperature in decoctions of any of the best known natural dye-stuffs, such as cochineal, logwood, madder, quercitron bark, &c., and then washed in water, it will be found that the fibres are simply discoloured, or stained of no definite shade; they have taken up but a small portion of colour from the decoction, and no real dyeing has taken place.

Use of Mordants.—To obtain permanent dyes from the great majority of native colouring materials the intervention of another class of bodies entirely different from either fibrous or colouring matter is found necessary; these bodies are called *mordants*. The term mordant is found in Latin and Italian manuscripts of the 12th and 13th century, as the name of an adhesive composition by means of which gold leaf could be attached to wood, marble, or metal; early dyers appropriated the word to designate a substance by means of which colouring matters could be made to adhere to fibre, and it has been retained in that sense in all modern treatises upon dyeing.

The chief mordants used in dyeing are salts of aluminium, iron, tin, chromium, copper, and a few other metals. When a decoction of a colouring matter, say logwood or cochineal, is heated with a small quantity of a properly chosen salt of one of these metals, it is found that the colouring principle loses its solubility, forms a combination with the metallic salt or its bases, and precipitates to the bottom of the solution, leaving the supernatant liquid nearly or quite colourless. The precipitate is usually called the "lake" of the particular metal and colouring matter, which are probably in a state of chemical combination; the lakes are insoluble in water, and are only split up again into their constituents by the action of somewhat powerful chemical agents.

Fibre cannot usually be dyed by means of ready formed lakes, for the reason that they are insoluble in water and not easily soluble in any menstruum which can be safely applied to such material, they are themselves of too coarse and gross a nature to penetrate the fibre, and when applied to it rest for the most part on the surface, and are therefore easily removable by washing or mechanical friction. It is known, however, that for some colours in calico-printing

lakes can be applied, but that is only in conjunction with acid salts and at a high temperature, by means of which a sort of solution is obtained while in contact with the fibre itself. The art of the dyer consists in so arranging these three elements—fibre, metallic salts, and colouring matter—that he may obtain the formation of the insoluble coloured lake in the body of the fibre itself, whereby either by the lake being mechanically retained or chemically combined the fibre is permanently coloured.

Application of Mordants.—There are three principal ways in which the mordant and colouring matter can be put into contact with the fibre, the developments and modifications of which constitute the whole art of dyeing.

1 By the first method, which is by far the most common, the fibrous matter is separately impregnated with the mordant, which is by various means decomposed, so as to deposit its base in an insoluble state upon or within the fibre, and afterwards the colouring matter is applied. Take, for example, the case of dyeing a common black from logwood upon calico, which has no affinity for the colouring matter of the logwood. The first process is to pass the calico through a hot aqueous solution of sulphate of iron, sometimes mixed with acetate of iron, and to remove the excess by passing the cloth through rollers; the cloth, either previously dried or not, is then passed through a mixture of lime and water which has the effect of decomposing the iron salts and liberating oxide of iron. A washing in water to remove the excess of lime or any loosely attached oxide of iron prepares the calico for coming into contact with the logwood. The calico, which has now a buff colour, owing to the attached mordant of oxide of iron, when placed in a hot decoction of logwood speedily acquires a dark line and in about half an hour has become dyed of a dense black colour, and, when smoothed and finished, forms the common black calico of the shops. A variety of other cases might be adduced, woollen cloth boiled for some time in bichromate of potash solution acquires a certain amount of a salt of chromium, which enables it to take a black colour from logwood, and other colours from other dye-stuffs. Woollen, boiled with salts of tin, is enabled to dye up a brilliant scarlet in decoction of cochineal; boiled with alum, it will take a great variety of colours in various dye stuffs. The practice of calico-printing illustrates in a very forcible manner the action of mordants, by the aid of apparatus described in the article upon that subject, portions of a piece of calico are impregnated with mordants, and these portions alone acquire colour from the dyeing solution, and thus designs or patterns are produced upon a white ground. The most usual method of impregnating the fibrous matter with mordant, consists in heating it with the required metallic salts, and it will be seen hereafter that easily decomposed salts are those preferably used; or substances such as chalk, alkalis, or tartar are added to some more stable salt, such as alum, to induce the formation of comparatively unstable compounds, which, under the influence of a high temperature and contact with fibrous matter undergo decomposition,—the metallic oxide or some basic insoluble compound of it becoming intimately combined with the fibre, which is then said to be mordanted.

2. A second method, less general than that above described, is to apply the colouring matter before the mordant. It is resorted to only with heavy goods which absorb a large quantity of liquid, or with light colours upon other fabrics, dyes produced in this way are superficial in their character, and not so permanent as those produced by the first method. In dyeing by that method it is in many cases customary to add a small quantity of mordant to the dye-bath when the process is quite or nearly finished, or to pass the dyed goods, as a final operation, through a diluted mordant.

3 A third method is to apply the mordant and the colouring matter together to the fibrous substance. In common piece-dyeing in weak liquids this plan is seldom followed, on account of the tendency to form insoluble lakes in the solution, which, depositing only on the external part of the fibres, give inferior results, alike as to stability of colour, depth of shade, and evenness or regularity of the dye. In calico printing or in padding, this method is of extended application and the inconveniences experienced in common dyeing are not perceptible, owing to the greater concentration of the mordanting salts and the use of thickening matter. Lakes are very probably formed to some extent during the preparation of the mixtures, but, the combination taking place in the presence of a fluid made viscons with gum or starch, the insoluble lake is in an extremely fine state of division, in such a mixture there is always present an acid or an acid salt, such as acetic acid, oxalic acid, tartaric acid, or alum, chloride of tin, cream of tartar, or bisulphate of potash. These tend, in the first instance, to restrain the formation of a lake, and afterwards, when the fibre and the mixture of mordant and colouring matter are submitted to heat, as in the process of steaming or stoving, facilitate the solution of any lake formed, which thus finds entrance into the fibrous matter, and there undergoes combination with it,

owing to decomposition of the mordanting salts, a true dyeing taking place.

PRACTICAL DYEING PROCESSES

By the foregoing preliminary observations the reader will have been prepared to comprehend the *rationale* of the practical processes of dyeing. In order to give a fairly comprehensive account of these, it has been found convenient to take the colours in the old arrangement of simple and compound colours. Red, blue, and yellow are supposed to be simple or primitive colours, the methods of obtaining these being given, then follow the colours from mixtures of two of the elementary colours, as green from yellow and blue, orange from red and yellow, and purple from red and blue. The colours not included in the above, and in the dyer's philosophy made by mixing the three elementary colours, red, blue, and yellow, in different proportions—namely, the browns, greys, and chocolates, and black—will be conveniently treated of after those supposed to result from the mixture of two of the primary colours.

This arrangement, though perfectly arbitrary, is both convenient and consistent as far as regards dyeing, for though modern discoveries in optics may show that pure blue and yellow do not make green, and may in other respects disturb the older ideas concerning primitive and secondary colours, yet the dyer has sufficient justification for retaining the old system, because he can show that his blue and yellow always make green, and that the proper mixture of the so-called simple colours produces a compound shade which can be calculated beforehand from the proportion of the respective colours employed.

Red Colours.

The most important of the red colours produced by dyeing are obtained from cochineal and from madder, the former being used for woollen and the latter for cotton goods. They are both old colours, and have arrived at their present excellence by slow degrees, they are deep and brilliant, and, as far as regards permanency, hold the highest position among all dyed colours. The processes employed are instructive as illustrating the diversity of treatment required by different fibres and colouring matters.

Red upon wool from cochineal—Let it be assumed that the shade of red required is fine scarlet, such as is worn by officers of the British army, and that the woollen cloth is of finest quality. The cloth first requires purifying from all the adventitious substances which it has acquired in the process of manufacture, in order to prevent irregularity and unevenness in the shade of colour; this is done by methods described in the article BLEACHING. The only materials required to produce a fast scarlet upon wool are oxide of tin and the colouring matter of cochineal, but it requires much practical skill to bring them into contact properly. After the cloth is cleaned, and while it is still wet from its last washing, it is mordanted by boiling it in a solution of a salt of tin with or without cream of tartar. The parts of the boilers not in actual contact with the fire are frequently constructed of pure black tin, or at least all parts out of water should be of this metal, or else protected by wood, or the dyeing vessel should be made entirely of wood and heated by steam pipes; for if the cloth containing the acid solution of tin comes in contact with a copper or brass surface it acquires a stain which afterwards dyes up an impure colour. What takes place in the course of boiling is that eventually a certain portion of tin, probably in the state of stannic oxide, becomes fixed upon or within the fibres of the wool, and this in a perfectly uniform manner. The tin not in intimate combination with the wool, or held merely by capillary attraction, is washed off by water before the cloth is brought into contact with the colouring matter.

The mordanted cloth is now brought into a boiler containing finely ground cochineal diffused through a sufficient quantity of water, to which it is usual to add some more tin mordant and tartar; the cloth is turned continually to prevent folds or creases from interfering with the free access of the dye to all parts of it. The contents of the boiler are heated to the boiling point, and in half an hour or so the liquid becomes nearly colourless, and the cloth is found dyed of a bright red.

The above may suffice to furnish a general view of the procedure usually followed, and to illustrate the principles involved with regard to numerous other dyes besides cochineal. To give the general reader a further idea of certain operations practised in the use of that colour (and the description applies more or less to others), the following particulars may be noted.

The tin mordant used for scarlet on wool—It is now 200 years since the discovery was made of the use of tin with cochineal for dyeing scarlet, it might be thought that by this time the exact kind and quantity of tin solution to be used would have been settled; there exists, however, the greatest diversity upon this point among practical dyers. The two salts of tin met with in commerce, designated by chemists stannous and stannic chlorides, have received various names from dyers. Crystallized stannous chloride is generally known as "tin crystal," the solution of the same as muriate of tin. A single muriate and a double muriate of tin are also distinguished, the difference being in the degree of concentration; but in some parts of the country double muriate of tin is the name given to a solution of stannic chloride, elsewhere called bichloride of tin, and a good deal of confusion is sometimes caused by the various uses of the trivial names of the solution of tin. Experience teaches the dyer that there are scarcely two dye-works in the world in exactly the same condition with regard to either water and air, or apparatus, or quality of materials, and that the nature and quantities of drugs, mordants, and dye-stuffs used, and the duration and temperatures of the operations which secure admirable results in one place are altogether unsuitable in another. It is, however, clear that by far the greater part of the variations introduced by practical dyers are not really founded upon necessity. Thus although the best colours can be obtained by the use of simple tin solutions manufactured on the large scale, in nine cases out of ten the operative dyer of scarlet insists upon preparing his own solution, and pretends that he employs special methods and preparations without which it would never be fit to use, and hence a countless number of tin solutions are in use.

Tin spirits—The solution of tin used by dyers for the scarlet and for many other colours upon wool, silks, and cotton, are commonly called spirits, or "tin spirits," a name which is very old, and appears to have originated in the use of nitric and hydrochloric acids to dissolve the tin, which acids were formerly, and are even at present, called spirits of nitre and spirits of salts. One solution which is a favourite, from the ease with which its metal goes to the wool, is the so-called nitrate of tin (sometimes called "bowl spirits," from being prepared in an earthenware bowl) made by dissolving thin metallic tin in moderately strong nitric acid. This is an operation requiring great care and some experience to prevent the formation of insoluble metastannic acid, the tin is added by small portions and gradually, so that the acid does not become hot, the solution takes place quietly, odorous nitrous oxide is evolved, and ammonia is formed. If the tin be added too rapidly to the acid, red fumes of nitric oxide are evolved, the liquid boils up, becomes thick from separation of metastannic acid, and is utterly useless as a mordant. This so-called nitrate of tin is a very unstable compound, decomposing spontaneously in a few days, so that it has to be prepared just as it is wanted, it is therefore not an article of commerce. The other very numerous "tin spirits" may be said to be solutions of tin in a mixture of nitric and hydrochloric acids; but the latter acid is sometimes replaced by the chlorides of sodium and ammonium, the resulting mordant being essentially a stannic chloride mixed with stannous chloride. Closely woven and loose woollen fabrics, such as yarn and flannel, require different tin mordants, as some mordants are more quickly decomposed than others. The result of using an easily decomposable mordant such as the nitrate of tin upon closely woven cloth would be the formation of a deposit upon the external fibres of the wool, the interior of the cloth being unaffected. For such cloth, therefore, a tin spirit which is only slowly decomposed, such as the muriate alone or mixed with tartar, must be chosen, so as to allow of a tolerably thorough saturation of the cloth before the breaking up of the mordant during the boiling. Here it may be observed that good, thick, and finely woven cloth which is dyed in the piece, that is, after weaving, is hardly ever completely dyed through, this can easily be shown by cutting through the cloth with a sharp knife, when the interior will be seen sometimes nearly white and generally much paler than the exterior; hence the preference which is given to cloth made from yarn dyed before weaving, the colours of which do not fade so readily as those of piece-dyed goods. Imperfection in the dyeing of the latter can by care, however, be reduced to a minimum, and in dark goods is hardly discernible.

Use of tartar with tin mordant—The "tartar" of the dyer is a more or less impure form of the cream of tartar of the shops, or the acid potassium tartrate of chemists. It is in very general use for wool dyeing, and when employed with dye-stuffs plays the part of an acid, and could in fact be replaced by an acid; in other cases, when used in mordanting, it no doubt acts as a salt, contributing to neutralize the strong mineral acids of the mordant, and rendering them more ready to decompose in the presence of the cloth. In a particular receipt for dyeing scarlet the proportions of materials are

as follows:—20 lb of tin solution, containing about 20 ounces of metallic tin dissolved in nitric acid, with the addition of a little common salt, are used to 100 lb of woollen cloth. Of the 20 lb of mordant, 13 lb are taken and mixed with a solution in water of 8 lb of crude tartar, and about 8 ounces of cochineal are added to enable the dyer to form a judgment of the progress of the mordanting. The ingredients having been boiled for a couple of hours, the cloth is rinsed in clean water and placed in another boiler, containing the residual 7 lb of mordant and 6 lb of ground cochineal, which are sufficient to dye up a full scarlet colour; but if the scarlet is required to be very bright, or what is called "fiery" coloured, a further quantity of tartar is added, this has the effect of somewhat reducing the depth of colour, and at the same time giving it a yellowish or orange hue, which for certain purposes is much desired.

Use of yellow in scarlet.—It appears that Baucroft, who wrote about the end of the last century, was the first to suggest that the bright fiery scarlet, which the dyers found they could best obtain by using a large quantity of tartar, might be produced more cheaply by adding some yellow colouring matter to the cochineal, or by first dyeing the cloth a light yellow; he tried the yellow from quercitron bark, and succeeded as far perhaps as was possible with that material. At any rate from his time it has been customary for dyers who do not aim at the highest degree of excellence in the scarlet colour to use a purified preparation of quercitron bark, commercially known as flavine, in conjunction with cochineal, other yellow colouring matters, such as fustic and turmeric, are also used. An admixture of these substances cheapens the cost of the colour, which can be made nearly equal in appearance to that obtained with cochineal alone, but it does not stand wear so well, and is more readily stained by various influences. The best scarlets are still dyed exclusively with cochineal.

Scarlets on wool from lac-dye.—The colouring matter of lac-dye is in its chemical properties and composition very similar to, if not quite identical with that of cochineal. As it is imported into this country from India, it is, however, less pure than average qualities of cochineal; and it is probably on account of its impurities that the dyer cannot obtain quite so good results as the best cochineal colours, although if skilful he may approach them very closely. Having been submitted to a preliminary treatment with acid to free it from alumina and other earthy matters used in its preparation, it is then applied exactly in the same way as cochineal. It is extensively used for a second class scarlet, and is believed to be somewhat more durable and stable even than cochineal. The red cloth so much used for military dress is reputed to be prepared mainly with lac-dye.

Crimson red on wool—This colour is also dyed with cochineal, but with a mordant of alum instead of tin. It is a far less important colour than the scarlet, and compared with it is dull and flat; it is, however, rich and durable, and combines excellently with other colours.

The mordanting of cloth by means of alum, an operation of capital importance for a large series of colours derived from all varieties of dye-stuffs, must now be noticed.

Alumming of wool—The method of mordanting with alum, generally called alumming, is practically a simple process, but the chemical principles involved have given rise to much debate amongst experimenters. The alumming is usually performed by boiling the wool for one or two hours in a solution of common alum mixed with tartar, a certain portion of alumina, or, it may be, of some compound of aluminium, becomes thus intimately combined with the wool, and forms a basis upon which a coloured lake may be produced with solutions of colouring matters. The chemical conditions are somewhat different here from those which obtain in the case of mordanting with tin; for the disposition of tin salts in dilute solutions to decompose even spontaneously is so manifest that it may readily be supposed that some action on the part of the wool takes place which induces the formation of oxide of tin. The great apparent stability of alum caused the explanation of its action given by Thenard and Roard to be for a long time accepted. They held that it was absorbed whole or unchanged by wool, which retained it by some undefined power, so that it could not be removed by cold water, and required to be heated twenty times with boiling water to dissolve it out. In the light of modern researches this explanation may be safely rejected as erroneous. What appears to be the true state of the case was mainly brought out by experiments of Havrez, suggested by the celebrated Belgian chemist Stas, and supported by further knowledge of the properties of alum discovered by Tichbourne and Naumann. In fact, alum, contrary to what was formerly thought, is particularly liable to decomposition, even when not in contact with fibrous matters which might possibly have an influence upon it. Naumann has shown that by simply heating a solution of alum, saturated in the cold to its boiling point, an insoluble basic compound is soon produced, so that, after prolonged heating, as much as 25 per cent. of the alumina is precipitated, and the liquid is found to have become acid. Beyond this fact it is proved that wool when placed in a solution of alum, containing pure sulphuric acid, has the property

of absorbing more acid than alum, this unequal absorption is attributed by Havrez to a kind of dialysis, which, together with the tendency of the alum to decompose, sufficiently explains the deposition of alumina upon the wool. The action of tartar in alumming, according to the same authority, is that of an acid salt, and its addition influences the nature of the mordant deposited in the same way as if an excess of alum were present, or as if other acid bodies, such as sulphuric acid, oxalic acid, &c., were added. The insoluble aluminous compound which separates from solution of alum on prolonged boiling in a glass flask could not act as a mordant, being indifferent or passive to colouring matters, when deposited on fibrous matter it does not adhere, but can be washed off, or when dry may be shaken off like dust, this, therefore, is not the alumina mordant, nor do the researches of Havrez really point out what the alumina mordant is, though they are valuable and suggestive as showing under what conditions either a basic or an acid aluminous deposit is formed. With the former, which is unfavourable for dyeing, a blue colour is given with logwood, and a purplish red with Brazil wood, with the latter, the wool dyes up a violet with logwood, and a purer red with Brazil wood. The basic state of the alumming results, it is supposed, from the deposition of hydrate of aluminium upon the wool, and is caused by having too little alum or too much water, by boiling for too long a time, or by the use of salts which have a neutralizing action upon the alum. It is easily induced, when the weight of wool is more than 15 times greater than that of the alum. In other circumstances the acid state results, in which the wool is said to fix first hydrate of alumina, and also hydrated sulphuric acid from the sulphate of alumina. These conclusions of Havrez cannot, however, be accepted as final or satisfactory, and there is still much to learn upon the principles of alumming and mordanting generally.

The wool being successfully alumed acquires a crimson colour by dyeing in cochineal, but, as before stated, this shade is not of much value.

The shades of red between scarlet and crimson reds proper, or cherry reds, are also dyed with tin mordant and cochineal in nearly the same way as the scarlet; but in order to avoid a yellowish tone, the natural cochineal may be mixed with the manufactured or modified material known as ammoniacal cochineal.

Ammoniacal cochineal—This is made by treating ground cochineal with concentrated aqueous ammonia for several days, the colouring matter undergoes important changes by this process, an amide is formed, and the effect upon the colouring matter is that tin mordants give with it no longer a scarlet, but rather a violet tone. Ammoniacal cochineal is much used in fine dyeing for pinks, and according to the proportion in which it is added to ordinary cochineal, the normal scarlet shade is gradually brought over to the red and even to the crimson.

Pink or rose colour upon wool—This shade is obtained from ammoniacal cochineal, mordanting previously in a mixture of tin solution, alum, and tartar, the quantity of tin mordant used is small, the alum being the essential basis.

Other red colours upon wool—The colours mentioned above are from cochineal or its congener lac-dye; there are several reds obtainable from other colouring matters, which, though less important, are still worthy of mention.

Madder red upon wool—This colour is wanting in brightness, but it is valuable for its stability, and has at times been largely used for common red military cloth. As a basis for browns, chocolates, and other dark colours, it is very suitable when its comparatively high cost is not an objection. To obtain madder red, the wool is boiled for two hours with a mixture of alum, tartar, and tin salt,—3 lb alum, 1 lb tartar, and 4 ounces of the tin solution being taken for 10 lb of cloth, after boiling, the cloth is rinsed in water to remove uncombined mordant, and then dyed with madder, or preferably its derivative garancin, with addition of a portion of tartar; the dyeing may be accomplished in an hour, the depth of colour varying with the amount of colouring matter used.

Artificial alizarin on wool—By employing artificial alizarin somewhat better shades of colour can be obtained, and even pink colours of much solidity produced. A process for obtaining a fast red on woollen yarn, from alizarin, is as follows—boil 10 lb wool for an hour and a half with 1½ lb sulphate of alumina and ½ lb tartar, rinse in water, and then dye with 6 to 7 ounces of artificial alizarin paste containing 10 per cent of dry matter, commence the dyeing cold, and gradually heat to boiling. Alizarin can be used as a basis for producing fast brown shades, by adding fustic and extract of indigo after the red has been developed, and if necessary, a further quantity of sulphate of alumina and tartar.

Red colours can also be obtained by using Brazil wood or other red woods instead of madder, they are, however, of a low class and seldom employed. Archil alone, without mordant, can yield a full crimson upon wool, but it is not very stable, and is, moreover, expensive.

Aniline reds upon wool—There are several artificial red dye-stuffs, which may be used for wool, but none possesses great excellence. The only one which resembles cochineal in its qualities is the recently discovered eosine; this, with an alumina mordant, gives upon wool a very good imitation of cochineal scarlet, but an imita-

tion only, for the colour fades rapidly in sunlight, and is easily washed out by soap and water. Substances similar to eosine, which have even still more recently appeared in trade, are called coccine and nopaline, they yield beautiful but perishable red colours on wool and silk.

Red colours on cotton—*Turkey red*—Cochineal, which is so suitable a colouring matter for wool, does not dye satisfactory colours upon vegetable fibres; but from very remote times the Hindus have possessed a process for dyeing a brilliant and extremely permanent red upon cotton fabrics by means of madder. This process travelled westward through the Levant into Turkey and Greece, the date of its introduction into Western Europe going no further back than the middle of the 18th century, at which period Greek dyers were induced to settle in France and make known the methods in use for the production of this much desired colour. The name Turkey red, or Adrianople red, was applied to calico dyed with it at the time that such goods could be obtained only from the East, and it still retains the name. So much was the colour esteemed that in 1765 the French Government circulated a pamphlet describing the best known methods of dyeing it on yarns, and some years afterwards, the British Government paid a sum of money to a Frenchman named Papillon, for disclosing the whole process of obtaining it. The dyeing of Turkey red upon cloth and yarn is now extensively carried on in Great Britain, and with great success. Turkey red is essentially a madder red with an aluminous basis, but differs from a common madder red by containing oil, and it is the fixing and combining of the oil with the fibre and the colour which constitutes its peculiarity. Divested of details the process of producing Turkey red may be divided into four stages:—(1) the oiling of the cloth, (2) mordanting with a salt of aluminium; (3) dyeing with madder, or its equivalents garancin or alizarin, and (4) the brightening of the dyed colour. The preparation of the cloth with oil is a process used in no other kind of dyeing; of its utility there can be no doubt, but all the attempts of chemists to explain the *rationale* of its action have failed. There are many modifications of the method of applying the oil, but the older and more commonly used process is to mix the oil with a dilute solution of potash or soda ash, so as to diffuse it uniformly through the liquid, forming an emulsion, the oil is not dissolved by the alkalies, nor is it supposed to combine with them, but is simply held in a state of excessively fine mechanical division. A low quality of olive oil is most generally used in Europe, that from Mogador, in the north of Africa, being very suitable. Certain kinds of oil do not answer for Turkey red, only those being suitable which, probably from containing free fatty acids or aluminous matters, readily form a milky emulsion with weak alkaline solutions; other kinds are, however, in use in some places. The cloth to be dyed is steeped in the oily emulsion, wrung out, and dried in a warm stove; this process is repeated six or eight times, and the cloth is finally washed in weak alkali to remove from it all the oil not intimately united to the fibre. The result of this treatment, which is the most delicate and important in the Turkey red process, is that the cloth becomes impregnated with a fatty matter, which by the contact of alkalies and heated air has undergone some change from its original state, which is usually called an oxidation, but the nature of which is really unknown. The cloth now possesses a power of attraction for mordants and colouring matters greatly superior to untreated cloth, and further, its physical condition is changed so that colours upon it are more transparent and more vivid than upon ordinary cotton.

The cloth in this state is ready for mordanting, which is done by passing it through a bath of alum, partly neutralized with carbonate of soda or by chalk, or in a bath of acetate of alumina, the object being to obtain a regular deposition of the aluminous base upon the fibre; the excess of mordant is carefully washed away from the cloth, which is now ready for dyeing.

The dyeing is accomplished in the ordinary way, by keeping the cloth in continual motion in a vessel containing heated water and the dye stuff, which may be madder, garancin, or artificial alizarin. It is a very general practice to add a quantity of ox-blood to the water used in dyeing Turkey red. What purpose this fulfils is not known, its colouring matter cannot be supposed to be of any use; its aluminous constituents may have some useful action, but this seems very doubtful, probably its addition is quite superfluous, and is retained from older times, when dyeing was less understood than at present. When the dyeing is completed the colour is a full and deep but dull red, which requires brightening. The brightening operations consist in removing brownish matters from the dye by boiling in soap and alkalies. To give a still more brilliant colour, the goods are boiled for several hours in a closed copper boiler with a mixture of salt of tin with the soap used in the last process of brightening,—occasionally under a pressure greater than that of the atmosphere, in order to obtain a temperature some degrees higher than 212° F.

In many processes of Turkey red dyeing, the cloth is treated with decoction of gall-nuts, or with sumach, after the preparation with oil and before the mordanting; this enables it more easily

to absorb and fix the aluminous mordant, but it is not essential, and is most generally omitted.

No allusion has been made to a number of excrementitious and other animal matters, which the old dyers used in the oiling process, such as sheep-dung, cow-dung, ox-bile, &c.; they can be dispensed with, and were employed probably from caprice and ignorance.

Barwood red—An imitation of Turkey red is obtained from barwood; it is much inferior both in beauty and stability to the real colour, but the ease with which it can be dyed, and the less costly nature of the materials employed, enable it to be sold at a much lower price, and for some purposes it is largely used. Barwood is one of the red dye stuffs of which the colouring matter is very slightly soluble in water, it is used in a state of fine powder. The cotton to be dyed is impregnated with a tin mordant by any of the means known to dyers, and then boiled with the dye-stuff; the colouring matter as it dissolves is fixed by the mordant, and the process is continued until the required shade is obtained. This wood, and a similar material called camwood, are also employed in woollen dyeing to give brownish reds, and to dye a "bottom" or foundation for indigo blue colours, by which some economy in indigo is effected, and a peculiar bloom on the blue is produced.

The class of woods represented by Brazil wood, do not yield good reds upon cotton.

Blue Colours.

The most important of the blue colouring matters is indigo. This may be said indeed to be the most important of all colouring matters, both as regards the large quantity and monetary value of what is produced and sold, and the permanence and solidity of the dyed colours, which it yields. The indigo dye is a manufactured article, prepared in the place of growth of the plant which produces it. The indigo plant could itself be used for dyeing, but from 200 to 250 lb of it would be required to produce the effect of a single pound of the prepared indigo. In England, and many other countries possessing a temperate climate, the species *Isatis tinctoria*, or woad, has been cultivated, and has been used from time immemorial for dyeing blue. Its comparative poverty in colouring matter has caused it long since to be disused by dyers as a source of colour; it is, however, employed by them in the preparation of their indigo vats, but rather as a convenient material to induce fermentation than as a dye.

Indigo is distinguished from nearly all other colouring matters by its complete insolubility *per se* in water and other ordinary solvents. It dissolves to a very slight extent in heated aniline, petroleum, and acetic acid, which upon cooling redeposit it, the only real solvent for it is anhydrous acetic acid mixed with a little sulphuric acid, from which water precipitates it unchanged, but this solvent is inapplicable in dyeing. But solubility is an essential condition for dyeing, and means have been found to obtain satisfactory solutions of indigo by circuitous methods which involve the temporary destruction of its blue colour and a change in its chemical composition. By various deoxidizing agents, indigo blue can be changed into a white substance, indigo white, which dissolves with facility in all alkaline liquids, forming a colourless or slightly yellow solution. On exposure to the air or other sources of oxygen, the solution yields the insoluble blue indigo, and permanently dyes any fibre which has been saturated with it.

This is the only case in which such a method of dyeing is applicable, and on that account it possesses much interest. We shall now proceed to describe some of the practical methods in use for indigo dyeing.

Fermentation process—The oldest of these, and one naturally suggested by the method employed in preparing the dye-stuff, is the process of fermentation in contact with lime, or sometimes soda or potash. During this process, gaseous or liquid substances are formed, which have the power of reducing indigo from the blue to the white state, and fitting it for dyeing. This ancient method has not been superseded in England at least, being employed at the present day for nearly all woollen goods dyed with indigo, the consumption of which is greater for woollen than for all other kinds of cloth.

The woad vat.—To a course of lectures upon dyeing, recently delivered by Mr Jarman before the Society of Arts, we are indebted for the substance of the following account of the woad vat used by the Yorkshire dyers. The materials employed are indigo, woad, madder, bran, and lime. For this process as for every other in which it is employed, the indigo must be reduced to the finest possible powder. It is generally ground mixed with water, in closed revolving cast-iron cylinders containing iron rollers or balls, for several days, or until the slime or pulp formed contains no visible particles of the dye-stuff. The proportions of materials employed are:

Lincolnshire woad	5 cwt.
Wheaten bran	18 lb.
Slaked lime in dry powder	22 "
Madder	2½ "
Indigo	24 "

The woad is first placed in the dyeing vat nearly filled with water, which is heated to between 140° and 150° F., after some hours (required to soften the woad), the bran, madder, and indigo are added, and half of the whole quantity of lime. In a few hours, if all is right, signs of commotion produced by fermentation will be visible, the liquid will become greenish, and a blue scum will be visible on the surface, a piece of wool is put in as a test, and if in a short time it becomes dyed blue the process is proceeding well; a little more lime is added, but at intervals, so as not to check the progressing fermentation, and, if it should become necessary, the vat is heated up by steam to its original temperature; on the third day the vat should be ready for dyeing. Such a vat as this requires skilful management to control the fermentation; without lime the reduced indigo would not be dissolved; with too much lime the fermentation would be stopped. The woad acts as an easily fermentable matter, and furnishes a portion of blue colour; the bran also no doubt is useful, on account of the ease with which it begins and promotes fermentation; the madder is probably of no use at all, its employment being still continued from an old unfounded notion that it gives some of its red colouring matter to the indigo-dyed goods, for the small amount of saccharine matter present in 2½ lb of madder cannot be held of any importance in the presence of 5 cwt. of woad.

A woad vat, when ready for dyeing, consists of a certain depth of a tolerably clear solution of white indigo in lime, and a somewhat voluminous semi-solid mass at the bottom, consisting of the bulk of the woad, the excess of the lime, the insoluble part of the madder, and the impurities always present in indigo. To keep the cloth to be dyed from contact with the muddy bottoms an iron hoop, of the internal diameter of the vat, covered with a network of open meshes is lowered into it and secured at a safe distance from the bottom.

The pieces to be dyed, after being well cleansed, are placed in the liquor, and kept in constant movement to insure full access of the colour to all parts. The time required to dye, varying from 20 minutes to two hours, will depend upon the fineness and weight of the cloth, and upon the depth of colour required, if the goods require it, they are dyed a second time. In moving the pieces about, they must not be brought above the surface of the liquid, for the oxygen of the air would restore the dissolved white indigo to its blue insoluble state. When the pieces are found to be sufficiently impregnated with the dye, they are withdrawn from the vat; at the moment of leaving the dyeing liquor they are seen to be of a yellowish colour, which almost instantly changes into a bright green, then darker green, and finally becomes blue through the absorption of oxygen by the white indigo. Loose wool or yarn is dyed by enclosing it in an open and movable network bag.

The vat above described can of course dye only a limited quantity of material, becoming after every operation poorer in indigo, but it is not necessary to re-set a vat. The strength of its contents is kept up by constant additions of indigo, lime, and bran; no more woad is added, the quantity used at first being sufficient for about its own weight of indigo.

Bran and molasses vat.—Another kind of indigo dye vat, very extensively used on the Continent, and highly spoken of by practical men, is prepared as follows. A vat 6 feet in diameter and 7 feet deep is filled with water warmed to 130° F.; then 4½ lb of ground indigo, 34 lb crystals of soda (or instead 16 lb soda ash) and 67 lb of bran, and twelve hours afterwards 2 lb slacked lime, are added; in 24 hours the indigo should commence to be dissolved, and a test strip of stuff plunged in the liquid should be speedily dyed, but some hours longer and the gradual addition of 18 or 20 lb more of lime are required to bring the liquor into its best condition. In this vat, as in the woad vat, the lime controls the fermentation of the bran, and has to be added with care. With each pound of indigo added to replace what has been removed from the vat during a day's dyeing ½ lb of molasses and ½ lb crystals of soda and 3 or 4 lb lime must be used. By daily replenishing the vat it can be used continually for four or five months; at the expiration of that time the bottoms must be removed; the supernatant liquor containing indigo in solution may be used instead of water for setting a fresh vat. This vat is said to have quite supplanted the old woad and madder vat, molasses being preferable on the score of cheapness and also of solubility.

The soda not being necessary for the solution of the indigo could be omitted in the setting of the vat, but it is reckoned useful in assisting the wool to take the dye, for the wool, however well it be bleached, is said to retain some greasy matters that yield to the soda, which thus enables the indigo to give fuller and faster colours than when lime alone is used.

It is to be observed that the two vats just described are what are distinguished as "warm vats," being made and worked at a temperature considerably above that of the air,—a condition held necessary for dyeing wool and some kinds of heavy cotton goods. For ordinary cotton dyeing the vats are used cold or at the ordinary temperature of the air, and are prepared in quite a different manner.

Copperas and lime vat.—A strong copperas and lime vat is composed as follows.—

900 gallons of water.
60 lb green copperas
36 lb ground indigo.
80 to 90 lb dry slaked lime.

These materials are well mixed together and raked up at intervals for say 24 hours, when the vat is ready for use. The lime decomposes the salt, liberating ferrous oxide, which acts upon the indigo, converting it into white indigo, which dissolves in the lime water. In large establishments for dyeing calico blue, it is usual to have a series of such vats in a row; the pieces to be dyed are tightly stretched on a frame and dipped in the liquid for from seven to ten minutes, after which they are believed to be as fully saturated as possible, the frames are next raised into the air, and in a few minutes the blue colour becomes developed; the same process is then repeated until the required depth of colour is obtained. By printing certain resisting compositions on the cloth previous to the dipping, white figures can be obtained upon a blue ground, producing what is known as the navy-blue style of print, formerly much worn by the lower classes in England. By combining suitable mordants with the resisting composition, not only white, but orange, yellow, and green coloured figures can be obtained upon the blue ground, but the production of these is rather a branch of calico printing than of dyeing proper.

Although this kind of vat is most generally used for the lighter qualities of calicoes, it can also be applied to such woollen goods as merinos, which are not very closely woven, and also to silks.

Hydro-sulphite of soda vat.—In 1871 Schützenberger and Lalande introduced a new reducing agent applicable to indigo dyeing, the so-called hydro-sulphite of soda, obtained by acting upon acid sulphate of soda with metallic zinc. It possesses the most energetic deoxidizing powers, and in the presence of alkalies almost immediately reduces and dissolves indigo. It has been applied both in dyeing and in printing indigo colours, but cannot be said to have succeeded in displacing the older kinds of vats, having the disadvantage of costing much more without producing any apparent improvement in the colour yielded.

By preparing a very strong indigo vat, and thickening the fluid with gum, it is possible to print indigo blue colours in designs, but the many difficulties attending the process have very much restricted its application.

The colour yielded by indigo, though far from brilliant, is extraordinarily permanent, and is much used for articles intended to withstand much wear and rough usage, and also as a basis for the best quality of black upon fine woollen cloth.

Sulphate of indigo.—When indigo is acted upon by concentrated sulphuric acid it forms a solution of the so-called sulphate or extract of indigo, which, though possessing an intensely blue colour, cannot by any means be made to furnish the original dye. This preparation of indigo is applied only in wool and silk dyeing, it gives blues which are tolerably bright, but possess none of the stability of those obtained from real indigo. For vegetable fibre it has no affinity whatever either with or without mordants.

Prussian blue.—This, perhaps the earliest of artificial dye-stuffs, was accidentally discovered in 1710, though not used in dyeing for some time afterwards. The simplest method of employing it consists in first impregnating the material to be dyed with peroxide of iron, and then passing it into a solution of yellow prussiate of potash acidified slightly with sulphuric acid. Prussian blue upon silks is thus dyed. The most convenient way of obtaining a deposit of the oxide of iron consists in soaking the silk in a somewhat strong solution of the ordinary dyers' nitrate of iron, in the course of two or three hours a certain quantity of the oxide is found to be intimately combined with the silk; the excess of nitrate is then washed away and the silk worked in the acidified prussiate bath, when it immediately assumes a light azure shade, by repeating the treatment several times any depth of colour may be obtained.

Calico can be dyed in the same way, but both for that and for silk it is usual to add to the iron solution a small quantity of salt of tin, which is useful in giving a purplish tone to the blue and preventing the production of a disagreeable greenish tinge.

A deep colour cannot in this way be satisfactorily given to woollen, for which a treatment is adopted depending upon a decomposition of the prussiate by means of heat and acids. For dyeing say 110 lb of merino the following proportions and methods may

be used. Dissolve 9 lb of yellow prussiate of potash in hot water, and add the solution to the required quantity of water, then add 14 lb sulphuric acid, 6 lb sal-ammoniac, and about 6 oz. of crystals of protochloride of tin, the merino is placed in the mixture, and the temperature of the dye-bath gradually raised to the boiling point in five hours. The blue gradually formed on the cloth requires brightening in a fresh bath consisting of alum, persalt of tin, and cream of tartar, heated to nearly the boiling point. Red prussiate of potash is used in nearly the same way to dye dark Prussian blues upon wool, but as it is more easily decomposed than the yellow prussiate a weaker acid-bath suffices. These blues are frequently finished off with logwood to give them a deeper tone.

Prussian blues can also be obtained on such woollen goods as merinoes, by a process of padding, and the use of a colour nearly identical with the so-called French or royal blue used by calico printers. A mixture is prepared as follows. Half a pound of wheat starch is boiled with about half a gallon of water, in the thin paste thus made 13 oz. of powdered yellow prussiate are dissolved, and afterwards 6 oz. of tartaric acid, when the mixture is quite cold 1 lb of prussiate of tin in paste is added, 1½ oz. oxalic acid, and 3 oz. sulphuric acid, the whole is well mixed and strained. The woollens to be treated are first "prepared," as it is called, by impregnating them uniformly with oxide of tin, and then the above thickened mixture is applied by means of rollers, so that it shall be evenly and smoothly spread over the whole stuff, the cloth is then dried and exposed to the action of steam, which causes the acids to react upon the prussiates, and from a nearly colourless mixture develops an intense blue, which is found to be permanently fixed in the fibre.

Aniline blues—There are several artificial blue dyes made from aniline and similar bodies, which yield very brilliant colours on wool and silk. They can be easily applied, the goods simply requiring to be worked in their aqueous solution until they have acquired a sufficiently dark tinge. An artificial dye called Nicholson's blue is differently applied, it is dissolved in an alkaline liquid, and forms then a colourless or nearly colourless solution, with which the goods to be dyed are impregnated, they are then passed into dilute acids, which develop the blue colour.

Litmus and logwood blues—The other substances which have been used for blue colours, such, for example, as litmus, are of little importance, and are now nearly unknown to the practical dyer. A blue can be obtained from logwood which has some resemblance to indigo blue upon wool, but it is of a very low character both as to stability and shade, and is hardly ever employed by respectable dyers.

Yellow Colours.

Yellow textiles, being less pleasing to the eye, and more readily soiled, are not nearly so much in use as those dyed with the two simple colours blue and red. The chief yellow dyes, besides fustic, are quercitron bark or its concentrated extract flavine, Avignon or Persian berries, and the now almost disused indigenous product, weld. The general mordant for these is tin, sometimes with addition of alum. One or two illustrations will suffice to show the methods of using them.

Fustic yellow—Fustic is probably the most generally employed yellow dye-stuff for wool, it gives yellows inclined to orange. For light shades it is not necessary to mordant the wool, it is simply well cleansed, and then heated with fustic decoction and some cream of tartar. For darker shades the wool is boiled with solution of tin and tartar, washed, and then worked in the decoction of fustic.

Picric acid yellow—Picric acid, one of the artificial colouring matters, gives pure though not deep yellow shades upon silk and wool without the aid of a mordant, the cleansed material being dyed by working it in a warm solution of the acid.

Chromate of lead yellow—The yellow most commonly employed for cotton goods is obtained by the use of salts of lead and bichromate of potash. The method of obtaining this colour differs somewhat from any previously described. The cotton, having been properly bleached, is impregnated with a salt of lead, usually by employing a solution of the acetate or sub-acetate of lead. The goods are next passed into a milk of lime solution, to which it is prudent to add some acetate of lead, in order to prevent the lime from dissolving the oxide of lead at first precipitated, the result of the lime treatment is that oxide of lead is evenly fixed upon the cotton, the excess of lime and lead is then well washed away, and the goods are passed into a solution of bichromate of potash, where they quickly acquire a bright and deep yellow colour, owing to the formation of the well-known pigment chrome yellow. To facilitate the combination, the bichromate of potash is mixed with as much sulphuric acid as suffices to liberate the whole of its chromium as chromic acid. The yellow-dyed goods require no further treatment than a good washing, the colour being quite fast. This yellow is, however, in very little demand, and in ninety-nine

cases out of a hundred it is immediately converted into an orange, by passing it through boiling lime-water, which produces the basic chromate known as chrome orange, which has always been in demand for many articles of wear.

Compound Colours.

The so-called simple colours—red, blue, and yellow—having now been dealt with, it remains to treat of their combinations, and this may be done briefly, the processes employed being for the most part similar to those already described. The compound shades in Chevreul's chromatic nomenclature amount to nearly 15,000, and it is very probable that fully that number are produced by the dyers of the present day. For practical treatment, however, the compound colours can be reduced to comparatively few classes. Mixing the simple colours one and one we obtain three compound colours,—blue and yellow give green, blue and red give purple, yellow and red give orange, while there may be a normal green, purple, and orange, it is evident that all the varieties of these several colours will depend upon the proportions of their constituents. If the three simple colours be mixed together, say in equal proportions, we may get a normal brown, or even a black; but if in unequal proportions, an immense number of shades, varying from the imagined normal brown to grey and drab, are produced. Although in many cases compound shades are produced by means of two or more simple colours, there are many natural as well as artificial dye stuffs which yield them ready formed, and frequently purer than they can be otherwise obtained. Most of these will be found mentioned in the following brief notice of practical processes in use.

GREEN COLOURS.

Lo-kao or Chinese green—Until about the middle of the present century there was not an instance known of any green on textiles which was not composed of the two separate colours blue and yellow. About that time some green-dyed cottons, imported into France from China, attracted the attention of chemists, who were surprised that they could not separate the green into blue and yellow constituents. Inquiries showed that the Chinese employed a green colouring matter called Lo-kao, until then unknown in Europe. It was a costly dye-stuff, selling in China for its weight of silver. Some quantity of it was imported and used in silk-dyeing by the French; it was not, however, found altogether satisfactory, and has at length been quite abandoned for the aniline greens, which are in every respect preferable.

Aniline green—There are two or three kinds of artificial green dyes in use, of which that known as methyl-aniline green, applied in silk dyeing, is most in request. The so-called indigo green has also been somewhat extensively employed for all kinds of fabrics.

These artificial and unstable materials are the only dye-stuffs for green possessed by the dyer, who is compelled to produce the colour by means of blue and yellow elements. The arsenical mineral green and the oxide of chromium green may be just mentioned as of extremely limited employ. The blues used in dyeing green are indigo, Prussian blue, and the sulphate of indigo. The yellows are afforded by Persian berries, quercitron, fustic, or the yellow chromate of lead. The processes employed consist, for the most part, in the separate application of the blue and yellow; for example, in dyeing a fast green upon wool from indigo and any of the yellow dye-stuffs, the blue is first produced as previously described, and the proper mordant for the yellow is then applied to the cloth, which is afterwards placed in the yellow colouring matter, the two colours are so intimately mixed as to be indistinguishable even by high magnifying powers. It may be observed that the reception of the blue does not to any perceptible extent diminish the power of the cloth to combine with the yellow.

Prussiate green—Prussian blue is employed as a basis in the same manner, only not being capable of resisting chemical agents so well as indigo blue, it demands more care. The greens with Prussian blue bases are more lively than those made with indigo, but are not so fast. Sulphate of indigo is even less stable than Prussian blue. It is, however, cheap and easy of application, and gives rich colours. The greens made with chromate of lead are for the most part confined to cotton goods, and are not in much demand.

ORANGE COLOURS.

For cotton the chief orange-dye is the chromate of lead compound already described. For other materials the orange colours employed

are nearly always composed of some of the red and yellow dyes mentioned in the preceding pages, such, for instance, as cochineal and fustic, which are applied in one bath, the same mordant serving for both.

Arnatto orange—A warm solution of arnatto in weak alkalies is used without mordant to impart to silk an agreeable orange shade. Its colour is generally considered too yellow, but may be made redder by treatment with weak acids, or by previously giving the silk a light red foundation.

Picric acid orange—Another orange on silk can be dyed by superimposing on a light pink a yellow obtained from picric acid.

Nitric acid orange—Silk can also be permanently stained of a yellowish orange by means of moderately strong nitric acid, which must, however, be applied with great care, since a more than momentary contact would be very injurious to the strength of the fibre. This method of dyeing silk was formerly much used for handkerchiefs, by protecting certain parts from the acid with melted wax or similar resists, white designs were produced upon an orange ground.

PURPLE COLOURS

The purple colours may be held to include all shades produced by an admixture of red and blue, such for example as lilac, violet, mauve, &c., and are of immense variety.

Aniline purples—Since their discovery aniline colours have been almost exclusively employed for dyeing silk and wool purple, yielding as they do shades which for lustre and purity surpass any obtainable from the older colouring matters, and possessing also a fair amount of stability. An aqueous solution of the dye without mordant is all that is required, and the goods when dyed need very little subsequent treatment. The aniline purples, violets, and mauves do not dye upon cotton without previous mordanting, and even then are so loose and unstable that they are only fitted for use where great fixity is not demanded, as for linings of clothing, &c. The most general mordant for the aniline purple colours on cotton consists of a tannate of tin obtained by first steeping the cotton in a solution of tannic acid, or in decoction of gall-nuts, sunnch, or myrobalans, all of which contain tannic acid; after a few hours' contact a considerable quantity of tannic acid has become firmly attached to the cotton, and the goods, being now treated successively with stannate of soda and dilute sulphuric acid or in other ways, acquire a certain proportion of oxide of tin, and are prepared to receive the colours.

Madder purple—But the purple colour *par excellence* upon cotton is obtained from madder or alizarin, the mordant being oxide of iron or a sub-salt of iron deposited on the fibre by treatment with the commercial pyrolignite of iron, commonly called iron liquor. This purple is remarkable for great permanency. It is very largely used in combination with black and white in the best kind of printed calicoes.

Archil purple—Archil and cudbear are sources of purple colours on wool and silk. The shades produced are rich and beautiful, they are not, however, very permanent, and have been nearly superseded by the aniline colours. Of the few instances that can be cited of stuffs dyed purple by the direct union of red and blue colouring matters, the violet or purple woollen cloth used for ecclesiastical purposes is an example. The indigo colour is first fixed and cleansed, and then the cloth is dyed with cochineal and tin mordants in the way already described for dyeing scarlet. The purple thus obtained is a fast colour, but is very costly, and on that account is not much worked.

The common shades of purple, violet, lilac, &c., upon wool are obtained from logwood with a mordant of alum and tartar, the red woods are sometimes employed in conjunction with logwood for these colours, which are "topped" with archil to give them more brilliancy.

The extensive range of colours, comprising all the shades of brown, bronze, chocolate, nut, wood, drab, and grey, which may be considered as compounded of the three elementary colours, some one of the three predominating, can only be briefly treated of in this article. Most of them are actually produced by the use of dye-stuffs yielding the three simple colours, but there are colouring matters like catechu, which themselves yield brown colours, and others, such as logwood, which may be held to contain two or more of the simple colours, the blue predominating. A few illustrations will show how these triply compounded colours are produced by the dyer.

BROWN COLOURS

Bronze brown on wool—The wool is mordanted with alum and tartar in the usual way, and is then dyed in a mixture of fustic and madder or other equivalent red and yellow dye-stuffs, for fast colours a blue part can be communicated to it by the indigo vat. For a lower class of colours no indigo is used, but instead, a mixture of yellow wood (fustic or quercitron) with madder for the red, and logwood for the blue part, or again, the sulphate of indigo may be employed for the blue.

Tan brown—According to Mr Jarman, the wool is mordanted

by boiling it for an hour with one per cent. of its weight of bichromate of potash, it is then washed, and transferred to the dyeing vessel, with the following percentages of its weight of materials—madder, 3 2, fustic, 4 8, camwood, 2, barwood, 1 75, sumach, 2 1, with these materials it is boiled for two hours.

Dark drab—From the same authority we take the following as the weights required to dye 100 lb wool, previously mordanted with 1 lb of bichromate of potash—camwood, 6 1/2 lb, sumach, 2 lb, madder, 2 1/2 lb; fustic, 4 lb, logwood, 2 1/2 lb, boil for one hour and a half, and afterwards, to darken the colour, pass into water containing 1 lb of sulphate of iron.

BLACK COLOURS

Black, from a dyer's point of view, is compounded of the three simple colours, red, yellow, and blue, in a state of concentration, but in reality the blue predominates in all good black colours, and gives them their density and at the same time their lustre. What is called a dead black, crape black, or jet black, is the nearest approach to a neutral black, but even this would be brownish if the blue did not predominate. It is often extremely difficult to obtain a black dye to suit a particular market. Of ten pieces appearing equally black to the uninitiated, an expert would, perhaps, pronounce one to be sooty, another purple, another red, another brown, another green, and so on.

We should have to go back some years in the history of dyeing, to find a time when black was actually dyed with the three elementary colours. In some processes blue from indigo was first applied, and then, upon an alum mordant, red and yellow from madder and weld respectively, such a colour was unexceptionable for stability, but its great cost caused it to be disused.

At the present day, logwood is the chief dye-stuff for blacks upon wool or cotton, and gall-nuts and other astringents for silks. Aniline black, on account of obstacles to its application, cannot be said to have yet established itself in dyeing proper, though it is much and highly valued in calico printing.

Black dye upon silk—Silk easily takes a black by treatment first with decoction of gall-nuts, and subsequently with a salt of iron. For blue blacks the silk is usually first dyed with Prussian blue, and then with gall-nut black. Extract of chestnut-wood with an iron mordant gives a good black. In modern black silk dyeing, materials are heaped upon the fibre which are not necessary to its colour, but which increase its weight in an extraordinary manner, so as not only to compensate for the loss of 25 per cent. of natural gum in the silk, but even, in some cases, to double or treble the original weight. The silk is, of course, much injured by the accumulation of foreign matters upon it, the fibre becoming harsh and brittle, and soon showing the effects of wear. The chief substances used for weighting are lead salts, catechu, iron, and galls, with soap or fatty matter, to soften in some degree the harshness of these occasions.

Black upon wool—Upon woollen cloth of fine quality, the black is dyed upon a basis of indigo blue, and, from the use of woad for this colour, such blacks are in England called "woaded blacks." The first process, therefore, in producing the best black is to dye the wool in the indigo vat of a tolerably deep shade of blue, and afterwards boil it in a mixture of logwood and sumach, treating it with sulphate of iron, the latter process being two or three times repeated, a very perfect and durable black is obtained, provided the indigo basis is sufficiently deep, and only a minimum quantity of logwood has been employed, say about one-fourth the weight of the sumach.

Common black—Common blacks upon wool have no indigo in their composition, but are dyed chiefly with logwood and iron salts, the wool and logwood are heated together for some time, and then sulphate of iron is added to the dye-bath. In other blacks of somewhat better quality, the woollen is boiled for some time with solution of iron, copper, and aluminium salts, together with tartar, and when the mordanting oxides have been fixed, the colour is dyed up in logwood. The bichromate of potash mordant can also be used for the black dye, and the cloth can be "bottomed" with camwood or barwood; it is then dyed up with logwood, to which fustic or sumach may be added.

Black upon cotton—Almost the only ordinary black in cotton dyeing is obtained from logwood with iron mordant, sumach is sometimes used, and very rarely the black is dyed upon an indigo blue basis by means of sumach or galls and iron. As before stated, aniline black has not yet been practically applied in dyeing cotton. A common method is to first heat the goods for some hours with decoction of sumach, wash mordant in sulphate of iron, and then dye in logwood, another method consists in fixing an iron basis upon the cotton by the method given above (page 573), and dyeing in logwood, along with a portion of sumach or fustic, according to the shade required.

Velvet dyeing—The most important branch of black dyeing upon cotton goods, is that employed for cotton velvets and velveteens, in which it is desired to produce a rich lustrous effect; the process is long, tedious, and uncertain, consisting of successive

applications of sumach, sulphate or acetate of iron, sulphate of copper, logwood, and fustic,—the end chiefly aimed at being the production of a black with bluish or violet bloom. The Manchester dyers formerly held a monopoly of this blue-black upon velvet, as it is called, but of late years the German dyers have shown themselves very formidable competitors in dyeing this class of goods.

THEORY OF DYEING.

When the great variety of processes employed in dyeing is taken into consideration, it is apparent that there must be some difficulty in constructing a general theory which shall be applicable to every case.

The earlier writers who endeavoured to generalize the principles of the art considered that the particles of colour were mechanically deposited in the pores of the fibre. The use of chemical substances in dyeing was held necessary only to dilate the pores for the admission of the particles, to prepare the particles for entrance into the pores, or to close up the pores after the colouring particles had entered. Mordants were held to be necessary because they formed cavities in the fibre adapted by their size and shape to receive and retain different kinds of coloured particles. About the middle of the last century Bergmann, observing the dyeing of wool by sulphate of indigo, considered that what took place was a purely chemical action, and that the matter of the wool entered into chemical combination with the dye-stuff, changing it from a soluble into an insoluble substance, and showing therein the power of chemical affinity. From this time the mechanical or physical theory of dyeing was supplanted by a chemical theory, in which all the observed facts were explained by the assumption that chemical forces operated between the fibre and the mordant, or the fibre and the colouring matter. A closer consideration by a later generation of chemists of all the phenomena of dyeing and of the nature of the materials employed did not tend to support this theory. About 1840 Dumas, the celebrated French chemist, and Crum of Thornliebank, a skilful chemist and a practical dyer, formally disputed the existence of a chemical action in dyeing, and referred the phenomena to physical causes of attraction on the part of the fibre. Crum confined himself to the single case of the dyeing of cotton, and expressed himself convinced that it was owing either to surface contact of the dye stuff with the cotton or to its entrance into the hollow tubes of the same, the colours produced in the first case not being so stable as in the other, as far as resisting friction went. The power which cotton fibre evidently possesses of appropriating oxides from solutions, as well as colouring matters, such as indigo, was viewed by Crum as a case of surface attraction, similar to the power residing in charcoal of abstracting oxides and colouring matters from solutions, and he declared there was no such thing as a chemical combination between the cellulose of the cotton fibre and any of the chemical substances or dye materials. To controvert this statement is difficult, for though the forces at work seem to be chemical forces, the products cannot be proved to be definite chemical compounds. On the other hand, the forces of catalysis, surface attraction, and powers of porous substances which Crum substitutes for the chemical forces of the older theories of dyeing, may be said to be merely names, without definite meaning, for indicating the existence of a class of phenomena not at all understood even at the present day. Dumas views the questions more broadly, and simply declines to accept as chemical phenomena actions which do not produce real chemical compounds. He considers that dyeing is more probably owing to a physical property of fibres by which they are enabled to attract and retain coloured bodies, much in the same way that animal charcoal does, and simply because the nature of the powers exercised by charcoal are not accepted as chemical, and no one knows what they are, dyeing cannot be considered as an effect of

chemical attraction or affinity. He admits, however, that there are some powers at work different from that possessed by charcoal. How is it, he asks, that wool takes up the scarlet dye so well under conditions where silk and cotton are barely tinged with colour? How is it that wool unites with the black precipitate formed with tannin and iron salts, while silk under the same circumstances is so difficult to dye? He asks, finally, how it is that certain colours can be fixed better on some fibres than others; and whether it is not by some special action, not correctly called affinity, but which at any rate is an important force, or the resultant of several forces, that this is affected. But, he continues, to confound chemical affinity, properly so called, with the phenomena of dyeing is to confound two very different things. When silk unites with Prussian blue, or wool with indigo, the action is quite distinct from what takes place when sulphur combines with lead. But, on the other hand, again, fibres are not to be looked upon as acting simply the part of a filter in retaining colours.

Chevreul, at a later date, insists that in the present state of our knowledge the phenomena of dyeing can be explained only upon chemical principles. He admits that colour may be and in practice is frequently deposited upon the external parts of fibres, but there are numerous cases in which a soluble salt is decomposed by fibrous matters, as when silk is steeped in persulphate of iron; and he cannot consider as anything else than chemical affinity that power which enables a solid body to decompose a solution of elements, themselves united by chemical affinity, and which without the contact of the solid body would have remained in perfect union. Many other chemists, physicists, and microscopists have occupied themselves upon this vexed question, but without evolving any generally acceptable theory of dyeing. The balance of opinion may be said to be in favour of the supposition that as far as regards the animal fibres, wool and silk, there are many cases of dyeing which can only be regarded as effected by chemical powers, with respect to the vegetable materials cotton and linen, the evidence is less certain, and we must wait for further research and investigation to settle the disputed question.

Bo's of Reference.—Of the numerous works upon dyeing it may be sufficient to mention Bacroff's *Philosophy of Permanent Colours* (21 ed. 1813); Bernholzer's *Éléments de la Teinture*, and Uri's translation of the same into English (1841); Persoz's *Traité de l'Impression des Tisus* (1846),—a most complete and accurate work for its date; O'Neill's *Chemistry of Calico Printing and Dyeing* (1860), and *Dictionary of Dyeing* (1862); Napier's *Manual of Dyeing* (31 ed. 1875); Schützenberger's *Traité des Matières Colorantes* (1867); Crookes's *Dyeing and Calico Printing* (1874); and Crace-Calvert's *Dyeing and Calico Printing* (1875). Of periodicals specially devoted to the application of colouring matters to textiles there is only one in Great Britain, *The Textile Colourist*; Germany has the *Färberei-Zeitung* and the *Muster-Zeitung*; in France there are the *Mouleur de la Teinture* and *Le Teinturier pratique*. Original articles upon the subject occasionally appear in the chemical journals, and especially in the *Bulletins of the Industrial Societies of Mulhouse and Rouen*. (C. O'N.)

DYER, JOHN. English poet, was born in 1699 or 1700 at Aberglasney, in Carmarthenshire, where his father, Robert Dyer, successfully practised as a solicitor. He was sent to Westminster school to be educated under Dr Friend, and was destined to succeed to his father's business. He showed, however, an inveterate dislike to the study of the law, and, having a taste for design, he induced his parents to allow him to adopt the profession of an artist. He wandered about South Wales, sketching landscapes and occasionally painting portraits. In 1726 his first poem, *Grongar Hill*, appeared in a miscellany published by Richard Savage, the poet. It was an irregular ode in the so-called Pindaric style, but Dyer entirely rewrote it into a loose measure of four cadences, and printed it separately in 1727. It had an immediate and brilliant success. *Grongar Hill*, as it now stands, is a short poem of only 150 lines,

describing in language of much freshness and picturesque charm the view from a hill overlooking the poet's native vale of Towy. Artless in an affected age, the natural images which crowd upon one another in this charming little poem are as admirable now as when they were written, and hold an assured place in English literature. Dyer's ambition to succeed as a painter impelled him to visit Italy, and about ten years after the publication of *Gongor Hill* he seems to have attained this great desire, and to have spent some time in the south of Europe. It was in consequence of this tour that he wrote his next poem, *The Ruins of Rome*, a descriptive piece in about 600 lines of Miltonic blank verse. In this work the phraseology is pompous and conventional, but there is considerable knowledge displayed, and the ardour of a true lover of antiquity. *The Ruins of Rome* appeared in 1740, and increased its author's reputation. Having fallen into bad health while painting in the Campagna, and finding that he was not destined to excel in the practice of art, he determined to enter into holy orders. In 1741 he was ordained by the bishop of Lincoln, and presented with the living of Calthorpe, in Leicestershire. He was married about this time to a lady descended from the brother of Shakespeare. In 1751 he was translated to the living of Belchford, in Lincolnshire, to which was added in 1752 that of Coningsby. In 1756 he exchanged Belchford for the wealthier incumbency of Kirby-on-Rane. In 1757 he published his longest work, the didactic epic of *The Fleece*, in four books, of which the first discoursed of the tending of sheep, the second of the shearing and preparation of the wool, the third of weaving, and the fourth of trade in woollen manufactures. The subject was prosy, and the stately blank verse in which it was discussed gave the poem a ridiculous air. The town took no interest in it, and the wits facetiously prophesied that "Mr Dyer would be buried in flannel." He did, in fact, very shortly afterwards follow his poem to the grave, for he died of consumption on the 24th of July 1758, leaving a wife and four children. After his death his genius was defended and his writings analyzed by Scott of Amwell, who published a commentary on Dyer's poems. The latter were collected by Dodsley in 1770, but they only form one small volume. *Gongor Hill* has been compared with Sir John Denham's *Cooper's Hill*, which may in some measure have suggested it. These two pieces remain the most important topographical poems in English literature, if we exclude Ben Jonson's *Penshurst*.

DYNAMICS properly means that science which treats of the action of force. Defining force as that which affects the motion of matter, it appears that the study of dynamics will lead to the consideration of the motion of material systems, and the laws in accordance with which this motion is changed by the mutual actions of the bodies forming such systems. But there is a sense in which we may contemplate the geometrical results of the motion of bodies without studying the forces under which, or the time during which, it takes place; and hence there are many problems which at first sight we might be disposed to include under the head of dynamics, but which also belong to the domain of pure mathematics, and may therefore more properly be considered as a branch of geometry. On the other hand, there is a branch of dynamics which treats of pure motion without taking any account of its subject or the means by which it is produced or changed. In this branch, to which the term kinematics, though first employed by Ampère in a wider sense, may with propriety be confined, it may seem that no consideration of matter or of force is involved; but, unlike the class just alluded to, the problems which come under this head involve explicitly the element of time, and it is only after studying the laws of dynamics that we are able to furnish a theoretical measure

of time satisfying the demands of the human mind. Thus any subject in which the measurement of time is involved enters on this account into the domain of dynamics.

Measurement of Time.—For ordinary purposes the rotation of the earth furnishes a sufficiently exact means of measuring time, and the observation of the transit of a known star is the best method we possess of determining the error of a clock, but that the fundamental conception of the measurement of intervals of time is based upon other foundation than the diurnal rotation of our planet at once appears from the fact that we see no inconsistency in asking whether the length of the day is the same now as it was 2000 years ago. If our primary conceptions of the measurement of time were derived from the earth's rotation, the absolute constancy of the length of the day would be a matter of definition. But it is not to the motion of the earth or of any other single body that we are indebted for our highest conception of the measurement of time—it is rather to the dynamical principle expressed in the first law of motion; and hence it is that the theoretical measurement of time, and of other physical quantities which explicitly involve time, must find a place under the head of dynamics. Kinematics may therefore properly be treated as a branch of dynamics, and for its discussion, as well as for the enunciation and explanation of the laws of motion, the reader is referred to the article on MECHANICS.

Perhaps there is nothing which appears to present a subject for study simpler than that afforded by the properties of space, and hence it is that geometry attained so high a reputation and made such rapid advances among the ancients. It was easy to construct material standards of length and by their means to measure approximately the linear dimensions of limited portions of space, the human mind being only too ready to believe in the constancy of the dimensions of the standards constructed; and thus the properties of space presented a subject which, at the very outset, afforded a facility for investigation which was wanting in the study of other physical quantities. The great simplification introduced by this belief in the permanence of the dimensions of material standards will be apparent if we consider the position in which we should be placed by the adoption of a different hypothesis. Once admit the supposition that the properties of a figure, as regards dimensions or form, depend explicitly on its position in space, or upon time, either by a process of growth in themselves or because space is changing its character, and the whole subject of geometry will require reconsideration.

Displacement.—A number of points or figures may be connected in accordance with such geometrical conditions that if one or more be displaced in a given manner the displacements of all the others may be determined. The determination of the displacement of each in terms of the given displacements is a problem in pure mathematics, and the branch of geometry which treats of such questions may be called the science of displacement. If we suppose the figures here contemplated to be material bodies, and the geometrical conditions to be determined by means of material constraints such as links, guides, teeth, and the like, the science of displacement thus applied becomes that of mechanism, and it is only necessary here to call attention to the following statements. First, in the study of displacements, or of pure mechanism, no account is taken of any but the geometrical properties of the bodies displaced, while the forces engaged in producing the displacement are entirely neglected: the consideration of the mechanical properties of the materials of which the parts of a machine are constructed, the forces acting between those parts, and the best means of "fitting" them, belongs to applied mechanics and machine construction. Secondly, the element of time is altogether left out of consideration; for,

although it may be argued that the displacement of each part of the system takes place in the same interval of time, and that the geometrical conditions enable us to compare the displacements experienced by different parts during the same time, and thus lead us to a comparison of velocities, yet it must be observed that this is *only* a comparison amounting simply to a relation between corresponding displacements, and does not involve time explicitly, since the whole displacement may take place in a time as long or as short as we please, for we do not consider it. Moreover, the actual motion of any part may be made uniform or varying in any arbitrary manner without any account being taken of it. In fact it is simply two or more configurations of the material system which are compared together, and, though for the sake of distinction we call one the initial and another the final configuration, we might as well distinguish them in any other manner and without stating which follows the other. Indeed we contemplate them as co-existent during the act of comparison. Hence we may complete the science of displacement or pure mechanism without ever considering force, or being able to measure time or even to define equal intervals.

Kinematics.—If to our conceptions of space and of displacement we couple that of time as a *measurable quantity*, we are led to compare the rates of non-simultaneous as well as of simultaneous displacements, and are consequently obliged to measure the *rate* at which displacement occurs by the change of position experienced in a *definite interval of time* by the body, figure, or point we are regarding. Rate of change of position measured thus we call *velocity*. The next step in the same direction is the consideration of the rate at which velocity changes, or *acceleration*, and thus the association of our conception of space with that of time as a measurable quantity opens up to us that branch of dynamics which we call kinematics.

Matter.—Having considered displacement in connection with the time during which it occurs, the next step leads us to take account of the thing displaced, and here we are obliged to contemplate matter directly. Matter, like time and space, we do not attempt to define, but treat it as a primary conception, its more obvious properties making themselves known to all through daily experience.

Force.—The change of the motion of material bodies brings us at once, through the introduction furnished by the first law of motion, to the conception of force, which may be defined in terms of three primary quantities, viz., space, time, and matter. The second law of motion expresses the manner in which matter is affected by force, and teaches us how to measure force by the observation of its effects.

The science of dynamics in its restricted sense is that which treats of the consequences arising from the relations of matter to force, and before we can proceed in this science beyond the first step we must become acquainted with the second law of motion, while kinematics requires for its complete development only the first law of motion, its range being thereby sharply defined and separated from that of the rest of dynamics. The laws of motion, like other natural laws, must be understood to express merely the properties of natural bodies as we find them, and within the degree of accuracy to which our experiments can be relied on. We might, of course, have started with any hypotheses we liked respecting the relations of force to matter, and upon these hypotheses and our conceptions of time and space have constructed a purely theoretical system of dynamics which would have been perfectly self-consistent; but our conclusions might, or might not, have agreed with observations of natural phenomena. If we found an agreement between the results of the application of our theory to special problems and the solutions of the corresponding problems as worked out objectively in nature,

we should have reason to believe that our hypotheses agreed with the facts, or, in other words, that they were true, and we should then raise them to the dignity of natural laws. It is on evidence of this kind that our acceptance of all natural laws is based. If our conclusions were inconsistent with natural phenomena our system of dynamics would be an abstract, instead of a natural, science—if, indeed, it might be called a science at all—and would be valuable merely as an intellectual exercise. In the case of such an abstract science we are not even bound to adopt the axioms respecting the properties of space which are usually accepted, but may confer upon our “space” any number of dimensions and any properties we please.

Stress.—Though the conception of a single force is convenient, it nevertheless results from a mere process of mental abstraction. We never meet with a single isolated force in nature, but each is accompanied by an equal and opposite force acting in the same straight line, and when we speak of one without the other we do so merely for the sake of brevity. The third law of motion implies this statement, though it has also a wider signification. The action and reaction which are thus always inseparably linked together may be conveniently called a stress, of which the two forces are opposite aspects. Thus it appears that there is nothing in nature corresponding to what we are accustomed to call a single force; stresses, indeed, abound, and may be produced whenever we please, but we are completely ignorant of their existence except when they change the relative velocities of different portions of matter. Then, and then only, do they appeal to our senses.

Statics.—The investigation of the conditions under which a system of stresses produces no displacement of the bodies between which they act constitutes the science of statics, and will be discussed under the head of MECHANICS.

Measurement of Force.—Since force can be defined in terms of space, time, and matter, it follows that the measurement of a force ought to involve measurements of these three quantities and of them only. Now it is plain that any force whatever may be chosen as the unit in terms of which other forces should be expressed, provided it is capable of being reproduced at all times and in all places with precision. We all now believe that the quantity of matter in a body is unchanged by changing its position or by the simple lapse of time, and we also believe that the region of space which we inhabit is sufficiently homoloidal to allow us to compare distances in different directions, at different places, and at different times. Moreover, the first law of motion, as has been stated above, provides, when proper precautions are taken, a method of measuring time which satisfies the requirements of the mind, while the rotation of the earth affords a practical measure of time sufficiently exact for the most refined experiments we can execute. Therefore a unit of force which depends only on the units of length, mass, and time will be the same at all places, and, so far as our experience allows us to judge, at all times. Such a unit is termed an absolute unit. Not only force but every other quantity dealt with in dynamical science, as well as every physical quantity whose relations to space, mass, and time are known, can be measured in terms of a unit of its own kind which depends only on the fundamental units of length, mass, and time, and is then said to be expressed in *absolute measure*. The three primary units must be chosen in an arbitrary manner, and their permanence must be considered a matter of definition; but when these have been once fixed, all the absolute units derived from them are perfectly determinate and invariable. If a foot, a pound, and a second be chosen as units, the corresponding absolute unit of force is called a *poundal*; while if the primary units be a centimetre, a gramme, and a second, the unit of force is called a *dynes*.

For the definitions of the derived dynamical units and the investigation of their dependence on the fundamental units, the reader may refer to the article on MECHANICS.

From what has been said it will appear that the whole difficulty in fixing upon a system of dynamical units lies in the determination of the fundamental units of length, mass, and time in such a manner that their constancy can be relied upon. The unit of mass offers very little difficulty in this respect. Long experience has taught us which are the most permanent of the varieties of matter we have at command. We have good reason to believe that a piece of platinum or an alloy of platinum and iridium may be exposed to pure air at ordinary temperatures for an indefinite time without any increase or diminution of its mass whatever. Such a piece of metal may therefore with propriety be chosen as a national standard of mass, the absolute constancy of the quantity of matter constituting it being accepted on definition, as we are unable to test it by any standard in which we have more confidence than we have in itself. The British and French national standards of mass are of platinum, but the new standards recently constructed in Paris consist of an alloy of platinum and iridium.

The determination of a unit of length is not so simple as that of the unit of mass. In this case, as in the preceding, we avail ourselves of the properties of a material standard, but we know that however indestructible the standard itself may be its dimensions depend upon the pressure to which it is exposed, its temperature, and in some cases upon other accidents, such as the magnetic force in the neighbourhood, &c. Hence the only course open to us is to determine as far as possible all the causes of variation in the length of our standard, and carefully to define its condition with respect to these variables, so that it shall be a standard only under the circumstances thus defined. Having thus defined the condition of the material standard with respect to all the variables upon which we know its length to depend, we must consider the absolute constancy of its length at all times and places to be a matter of definition until we have discovered other causes which affect it. It has been proposed that the wave length *in vacuo* of a particular kind of light, as for instance that corresponding to one of the sodium lines, should be taken as the unit of length, and its period as the unit of time. These units are probably more constant than those afforded by any material standards or vibrating springs which we can construct; but a belief in their absolute constancy implies complete confidence in the constancy of the properties of the interstellar medium, and of the sodium molecule.

The determination of a satisfactory means of measuring time seems to offer greater difficulties than the measurement of mass or of space, though the difficulties are of the same character as those we have just considered. The great difficulty consists in defining what is meant by the equality of two intervals of time which do not commence simultaneously. Remembering that it is upon the properties of matter alone that we can rely for assistance, we might construct a spring and define as equal lapses of time those intervals during which this spring executes the same number of vibrations, the temperature, &c., being kept constant. But if we were to construct a number of such springs, though a perfect agreement might obtain between them at first, we should find after a considerable period that the measurements of time derived from different springs did not agree, while our knowledge is insufficient to enable us to apply to each the corrections necessary to lead us to a consistent result. Now there may be no reason why we should prefer one spring above all the others, and thus it appears that a definition of equal intervals of time based upon the behaviour of any single

spring is too arbitrary to be satisfactory. If, however, we found a large number of springs, constructed of different materials and differently affected by temperature and other known causes of variation, continue to give perfectly consistent results, the theory of probability would lead us to place a high value upon the measure of time thus afforded. Now, we have stated that our highest conception of the measurement of time is derived from the dynamical principle expressed in the first law of motion, but when we come to apply this it is impossible to determine *a priori* whether in the case of two given bodies there is no stress acting between them or between one of them and some third object. Consequently, the only course open to us is to examine the motion of a large number of material systems, making such corrections for the action of stresses which we know to be in operation as our theoretical dynamics will enable us to determine; and, if after this we find that several independent systems afford the same measurement of time, while those systems which lead to a different result disagree also among themselves, we must accept the measurement of time afforded by the first set as the true measure, and attribute the discrepancies manifested by the other systems to some unknown stresses, which it should be our subsequent business to discover.

Work.—The contemplation of a stress, together with a relative displacement of the portions of matter between which it acts, introduces us to the conception of *work*. If we consider a stress, together with the distance through which the solicited bodies are capable of moving relative to one another in obedience to the stress, the object of our contemplation is the work which may be done under the given conditions of the system, and this we call *energy*. The subject of which natural philosophy treats is the transformation of energy, which in all its phases takes place in accordance with two great principles, known respectively as the principles of the conservation and the dissipation of energy. Of these two principles the former rests upon a much higher scientific basis than the latter. In order to lose our faith in the principle of the conservation of energy we must give up our belief in the fundamental principles of dynamics expressed in the laws of motion; but as regards the dissipation of energy we can say little more than that all the operations of nature with which we are acquainted take place in accordance with this principle. Clerk Maxwell has, however, shown that it is possible to subvert the principle of the dissipation of energy by the simple exercise of a sufficiently high order of intelligence. For the statement and discussion of these two principles see ENERGY.

It is the work of the natural philosopher to explain the operations of nature in accordance with the principles of dynamics, and we consider that we understand any phenomenon when we have shown it to consist of a motion of matter and determined the character of this motion. Thus it is that dynamics forms the foundation of every branch of natural philosophy, and a thorough appreciation of the principles of conservation and dissipation of energy is the only safe guide in physical investigations. (w. c.)

DYNAMITE (*δύναμις*, strength), the name applied to various explosive preparations containing nitroglycerin. The first practical application of nitroglycerin, discovered by Sobrero in 1847, was made by Alfred Nobel, who in 1863 used gunpowder soaked with it for blasting. In 1864 he found that it could be exploded by the initiative detonation of fulminating materials; and in 1867, owing to the uncertainty and danger attending its employment, he conceived the idea of mixing it with some solid and absorbent inert substance. The siliceous infusorial earth called in Germany *Kieselguhr* proved to be well adapted for this purpose, since it took up as much as three times its weight of nitroglycerin without becoming more than damp to the

touch. The mixture of earth and nitroglycerin, to which was added a little alkaline material to neutralize any acid that might be set free by the latter, was termed by Nobel dynamite. Ignited in the open air, dynamite burns slowly, but it is as readily exploded as nitroglycerin itself by means of a detonating fuze; and, though not equal in bursting or breaking power to uncombined nitroglycerin, on account of the absorption by its inert constituents of part of the heat developed by the exploding shock, it is greatly superior to gunpowder, instead of which or gun-cotton it is employed in blasting coal and stone, removing piles, felling trees, and clearing stumps from forest-land. It may also be used with advantage for the destruction of cannon and for breaking up large iron castings (see *Compt. rend.*, lxxii. 770). For filling bore-holes its pasty consistency renders it a very convenient material.

In continuous masses dynamite transmits detonation at the rate of from 19,500 to 21,600 feet a second. Confinement is not requisite for its explosion, and it can be used in damp situations without to any great extent impairing its action. It explodes if heated in a closed brass case, also on sharp percussion when placed between two metallic surfaces; it should not, therefore, be kept in hermetically sealed receptacles of metal or other very solid material. At a low temperature dynamite loses its tendency to explode by detonation. Another defect is its liability to part with a portion of its nitroglycerin, especially when in contact with porous substances, such as the paper of cartridges and wrappers (see Guyot, *Compt. rend.*, lxxii. 688). MM Girard, Millot, and Vogt have shown (*Moniteur scientifique*, xiii. 58) that for the manufacture of dynamite the best absorbents are kaolin, tripoli, alumina, and sugar; the last, like alum, the material employed in Mr Horsley's preparation, has the advantage of being separable from associated nitroglycerin by solution in water. Dynamite as made by M. P. Champion consisted of 20 to 25 parts of nitroglycerin with 75 to 80 parts of finely pulverized burnt clay from glass works (*Monit. scient.*, xiii. 91), and in some explosives sold as dynamite a mixture of sawdust and chalk is substituted for siliceous substances.

See F A Abel, *On Recent Investigations and Applications of Explosive Agents*, 1871, J. Trautl, *Die Dynamite, ihre Eigenschaften und Gebrauchsweise*, Berlin, 1876.

DYNAMOMETER (*δύναμις*, strength, and *μέτρον*, a measure), an instrument for measuring force exerted by men, animals, and machines. One of the simplest forms, namely, that devised by the mechanician Graham, and improved by Desaguliers, was essentially a steel-yard in which the position of the weight on the longer arm indicated the force exerted on the shorter in order to produce equilibrium. The dynamometer invented by Leroy of the French Academy consisted of a metallic tube 10 to 12 inches long, in which was a spiral spring with an attached graduated rod terminating above in a globe. Pressure being applied to the globe, the rod sank into the tube, and thus marked the force employed in compressing the spring. M. Regnier's dynamometer (see *Journ. de l'École Polytechnique*, tom. ii.) consists of an elliptical steel spring having fixed to one of its arms a semicircular graduated brass plate with central index, and to the other a small lever, which, acting on the index, shows the amount of force exerted in effecting a greater or less approximation of the arms to each other. In a similar instrument contrived by M. Poncelet, the springs are hinged together at the extremities, and separated from each other in proportion to the tension brought to bear upon them. A dynamometer for therapeutical purposes, invented by Dr Hamilton of Long Island College Hospital, consists of an india-rubber bulb filled with coloured water, into which dips a tube closed at the upper end. Pressure being applied to the bulb, some of the water is forced up

into the tube, the graduations upon which show the amount of pressure upon the air within it which is exerted by the water. By the dynamometer of Colonel Morin a curve is drawn, the area of which represents the product of the force exerted into the space through which it acts, or, in other words, the quantity of work performed in a given time. Details with respect to Morin's, Watt's, and other dynamometers will be found in vol. i. of Laboulaye's *Dictionnaire des Arts et Manufactures*.

DYRRACHIUM. See DURAZZO.

DYSART, a seaport town and royal and parliamentary burgh of Scotland, in the county of Fife, nine miles north-east of Burntisland, with a station on the North British Railway. It consists mainly of three narrow streets with a square in the centre, and on the whole has rather a dull and deserted appearance. In the High Street there are a number of antique houses with inscriptions and dates; and towards the south side of the town there are remains of an ancient chapel. Besides the old parish church with its tower, there are six places of worship, an old town-house, a mechanics' institute, and a combination poorhouse. The harbour is tolerably good, and there is a wet dock attached. The staple industry is the manufacture of linens and ticks; but flax-spinning and ship-building are also carried on, and there is a large export of coal. To the west of the town is Dysart House, the residence of the earl of Rosslyn. As a parliamentary borough Dysart is a member of the Kirkcaldy district. The population of the town in 1871 was 2476.

Dysart is mentioned as early as 874 at the time of a Danish invasion. Its name is said to be a corruption of the Latin *desertum*, a desert, applied to a cave on the sea-shore which was occupied about 440 by St Serf or Sanctus Servanus, to whom at a later date the church was dedicated. From James V the town received the rights of a royal burgh. In the 15th and 16th centuries it was the seat of a great manufacture of salt, and besides dealing in this article with Holland and other countries, it had a large general trade. For several months in 1559 it was the headquarters of the Lords of the Congregation, and in 1607 it was the scene of those remarkable meetings of the synod of Fife known in ecclesiastical history as the Three Synods of Dysart. William Murray, a native of the town, was made earl of Dysart either by Charles I or Charles II., and his eldest daughter afterwards assumed the title of countess, and transmitted the dignity to her descendants by the earl of Lauderdale, her second husband.

DYSENTERY (from the prefix *δυσ*, and *ἄστρον*, the intestine), also called Bloody Flux, an infectious disease with a local lesion in the form of inflammation and ulceration of the lower portion of the bowels.

Although at one time a common disease in Great Britain, dysentery is now very rarely met with there, and is for the most part confined to warm countries, where it is the cause of a large amount of mortality.

Dysentery in a sporadic form may occur anywhere, but this variety of the disease is believed to depend on a different cause from that to which it is due where it prevails endemically or spreads as an epidemic; for, while isolated cases appear capable of being excited by irritating causes which act locally on the alimentary canal, and may thus be developed out of an ordinary intestinal catarrh, the dysentery of tropical climates is generally regarded as owing its origin to a specific poison of the nature of a miasm or germ, somewhat analogous to that which is believed to be the cause of malignant cholera. How, and under what circumstances, the dysentery poison is generated is still a matter of uncertainty. The frequent association of dysentery with intermittent fever has long been remarked, and has led to the belief on the part of many in a malarial origin for this disease. It is, however, doubtful whether any necessary relationship can be established between them (although a malarial form of dysentery is a well marked variety of the disease), since dysentery may be found prevailing where no evidence of malaria can be detected. At the same time

certain characters of climate and soil are known to favour the increase and propagation of dysentery. Long continued high temperature of the air and ground, such as exists in the tropics, together with a soil of swampy character, are the conditions generally present where dysentery prevails endemically, and where it is propagated as an epidemic these factors are seldom absent. Among other causes well recognized as favouring the spread of epidemic dysentery are impure air and water, improper and insufficient food, unripe fruit, excessive indulgence in alcoholic liquors, and exposure to chills in warm weather, all or many of which have been often found connected with the propagation of dysentery among large bodies of people, as in the case of armies, where also the disease has been frequently associated with outbreaks of scurvy.

The contagiousness of epidemic dysentery is generally admitted, and it is probable that in this disease as in cholera the vehicle of its transmission is contained in the matter discharged from the bowels of those affected.

Dysentery manifests itself with varying degrees of intensity, but in well-marked cases the following are the chief symptoms. The attack is commonly preceded by certain premonitory indications in the form of general illness, loss of appetite, and some amount of diarrhœa, which gradually increases in severity, and is accompanied with griping pains in the abdomen (tormina). The discharges from the bowels succeed each other with great frequency, and the painful feeling of pressure downwards (tenesmus) becomes so intense that the patient is constantly desiring to defecate. The matters passed from the bowels, which at first resemble those of ordinary diarrhœa, soon change their character, becoming scanty, mucous or slimy, and subsequently mixed with, or consisting wholly of, blood, along with shreds of exudation thrown off from the mucous membrane of the intestine. The evacuations possess a peculiarly offensive odour characteristic of the disease. Although the constitutional disturbance is at first comparatively slight, it increases with the advance of the disease, and febrile symptoms come on attended with urgent thirst and scanty and painful flow of urine. Along with this the nervous depression is very marked, and the state of prostration to which the patient is reduced can scarcely be exceeded. Should no improvement occur death may take place in from one to three weeks, either from repeated losses of blood, or from gradual exhaustion consequent on the continuance of the symptoms, in which case the discharges from the bowels become more offensive and are passed involuntarily.

When, on the other hand, the disease is checked, the signs of improvement are shown in the cessation of the pain, in the evacuations being less frequent and more natural, and in relief from the state of extreme depression. Convalescence is, however, generally slow, and recovery may be imperfect—the disease continuing in a chronic form, which may exist for a variable length of time, giving rise to much suffering, and not unfrequently leading to an ultimately fatal result.

Several varieties of dysentery are described in which the symptoms are modified by the association of the disease with other morbid conditions. Thus the form known as Malarial Dysentery is complicated with febrile attacks of an intermittent character, and is frequently attended with hepatic, splenic, and renal affections; while it is most successfully treated by remedies which are of value in malarial diseases, such as quinine. Again, in Scorbutic Dysentery the attack is accompanied with the great prostration characteristic of scorbutus, and also with dangerous hemorrhage. Malignant Dysentery is the term applied to those cases where all the symptoms are present in great intensity, and progress rapidly to a fatal termination. Such cases are

often attended with gangrene and sloughing of the mucous membrane of the affected portion of the bowel.

The dysentery poison appears to exert its effects upon the glandular structures of the large intestine, particularly in its lower part. In the milder forms of the disease there is simply a congested or inflamed condition of the mucous membrane, with perhaps some inflammatory exudation on its surface, which is passed off by the discharges from the bowels. But in the more severe forms ulceration of the mucous membrane takes place. Commencing in and around the solitary glands of the large intestine in the form of exudations, these ulcers, small at first, enlarge and run into each other, till a large portion of the bowel may be implicated in the ulcerative process. Should the disease be arrested these ulcers may heal entirely, but occasionally they remain, causing more or less disorganization of the coats of the intestines, as is often found in chronic dysentery. Sometimes, though rarely, the ulcers perforate the intestines, causing rapidly fatal inflammation of the peritoneum, or they may erode a blood vessel and produce violent hemorrhage. Even where they undergo healing they may cause such a stricture of the calibre of the intestinal canal as to give rise to the symptoms of obstruction which ultimately prove fatal.

The occurrence of abscess of the liver in connection with attacks of dysentery is frequently observed. It has been ascribed to the passage of morbid material from the diseased intestine into the liver, but by many high authorities is regarded more as a coincidence, depending upon the same climatic causes as those which predispose to the dysentery.

Treatment.—Where the disease is endemic or is prevailing epidemically, it is of great importance to use all preventive measures, and for this purpose the avoidance of all causes likely to precipitate an attack is to be enjoined. Exposure to cold after heat, the use of unripe fruit, and intemperance in eating and drinking should be forbidden; and the utmost care taken as to the quality of the food and drinking water. In houses or hospitals where cases of the disease are under treatment, disinfectants should be freely employed, and the evacuations of the patients removed as speedily as possible. In the milder varieties of this complaint, such as those occurring sporadically, and where the symptoms are probably due to matters in the bowels setting up the dysenteric irritation, the employment of diaphoretic medicines is to be recommended, and the administration of such a laxative as castor-oil, to which a small quantity of laudanum has been added, will often, by removing the source of the mischief, arrest the attack. In the severer forms of the disease, those, namely, occurring in warm climates, the remedy most to be relied on is ipecacuanha. This drug, which has long been known as possessing special efficacy in dysentery (and was originally introduced into this country from Peru as the *radix anti-dysenterica*), has proved of signal value in the treatment of the disease in India, and, as shown by Dr Maclean, has diminished the mortality to a remarkable extent. It is administered in full doses of 25–30 grains of the powder, which are repeated in from six to ten hours, gradually lessening the quantity; the effect observable is a diminution in the pain, and in the frequency and offensive character of the stools, along with the accession of profuse perspiration and quiet sleep. Hot opiate fomentations applied to the abdomen are of use in relieving the tenesmus. Ice may be freely taken to allay thirst. The diet should be light, consisting of soups and farinaceous food. In malarial dysentery quinine is the most successful remedy, ipecacuanha being generally found to be unsuitable, while in scorbutic dysentery the treatment must bear reference to the depraved condition of the general health characteristic of scorbutus. In this form

of the disease the fresh bael or bhul fruit (*Ægle Marmelos*) is largely used in India. In chronic dysentery the administration of astringents such as Dover's powder may be of service, but the chief points to be attended to are the nourishing of the patient and the observance of judicious hygienic measures, such as the due clothing of the body, the use of tonics, baths, &c. A change to a cooler climate often proves of great value. (J. O. A.)

DYSPEPSIA (from *δυσ*, and *πέπω*, to digest), or Indigestion, is one of the most common of all complaints, but, from its intimate connection with various other morbid conditions, the term is somewhat vaguely employed. There are comparatively few diseases of any moment where some of the phenomena of dyspepsia are not present as associated symptoms, and not unfrequently these exist to such a degree as to mask the real disease of which they are only complications. This is especially the case in many organic diseases of the alimentary canal, in which the symptoms of dyspepsia are often the most prominent. In its restricted meaning, however (and it is to this that the present brief notice applies), the term is used to describe a functional derangement of the natural process of digestion, apart from any structural change in the organs concerned in the act. The causes of this ailment are very numerous, but are generally regarded as bearing reference either to the food, the condition of the gastric juice, or the movements of the stomach during the process of digestion.

Among the causes connected with the food are not only the indulgence in indigestible articles of diet, but the too common practice of eating too much of what may be otherwise quite wholesome and digestible, irregular or too frequent meals, and imperfect mastication of the food. Substances which are badly cooked, or too hot or too cold, the excessive use of condiments, the partaking of too much liquid with a meal, and over indulgence in tea, tobacco, and alcoholic liquors are likewise fruitful sources of dyspepsia. Morbid states of the gastric juice readily give rise to dyspepsia. This fluid may be diminished in quantity, or be altered in character by the presence of too much acid, or by deficiency in its active digestive principle, pepsin. These conditions are often connected with actual disease of the mucous membrane of the stomach, but they may also exist in advanced life, in depraved states of the general health (as in rheumatism, gout, Bright's disease, anæmia, &c.), or in constitutions weakened by fatigue, over-anxiety, or debauchery. It must, however, be borne in mind that not only the gastric juice but the other digestive fluids, such as the saliva, bile, pancreatic and intestinal juices, may by defects in their amount or quality materially hinder the process of digestion. Further, dyspepsia may be the result of a perverted condition of the natural movements of the stomach during digestion,—whereby, on the one hand, owing to increased activity of its propulsive power, the food may be carried into the intestines in a half dissolved state, and give rise to many of the symptoms of indigestion, or, on the other hand, from a weakened or atonic state of the muscular coats of the stomach digestion may be retarded, and the food retained and excite discomfort and pain consequent on its undergoing fermentive and putrefactive changes.

The symptoms of dyspepsia, even when due to a like cause, are so numerous and diversified in different individuals that probably no description could exactly represent them as they occur in any given case. All that can be here attempted is to mention some of the more prominent morbid phenomena usually present in greater or less degree.

When the attack is dependent on some error in diet, and the dyspepsia consequently more of an acute character, there is often pain followed with sickness and vomiting of

the offensive matters, after which the patient soon regains his former healthy state. What are commonly known as "bilious attacks" are frequently of this character. In the more chronic cases of dyspepsia the symptoms are somewhat different. A sensation of discomfort comes on shortly after a meal, and is more of the nature of weight and distension in the stomach than of actual pain, although this too may be present. These feelings may come on after each meal, or only after certain meals, and they may arise irrespective of the kind of food taken, or only after certain articles of diet. As in most of such cases the food is long retained in the stomach, it is apt to undergo fermentive changes, one of the results of which is the accumulation of gases which cause flatulence and eructations of an acid or foul character. Occasionally quantities of hot, sour, tasteless, or bitter fluid, or mouthfuls of half-digested food, regurgitate from the stomach. Temporary relief may be obtained when another meal is taken, but soon the uncomfortable sensations return as before. The appetite is often diminished, but may be little impaired, the tongue is in general large and flabby, and more or less furred. In some forms of this complaint, however, particularly where there is great irritability of the stomach, the tongue is abnormally red. There is generally obstinate constipation.

Numerous disagreeable and painful sensations in other parts are experienced, and are indeed often more distressing than the merely gastric symptoms. Pains in the chest, shortness of breathing, palpitation, headache, giddiness, affections of vision, coldness of the extremities, and general languor are common accompaniments of dyspepsia; while the nervous phenomena are specially troublesome in the form of sleeplessness, irritability, despondency, and hypochondriasis.

A disease of this nature, interfering as it does with the assimilative and nutritive processes, must necessarily exert an evil influence on the general health, and there is reason to believe that many serious ailments owe their origin to persistent dyspepsia. This is notably the case as regards phthisis; for although dyspeptic symptoms often present themselves as complications induced by the disease, yet it cannot be doubted that long-continued indigestion, particularly in youth, must have the effect of favouring the occurrence of consumption in persons at all predisposed to it.

Dyspepsia appears to be in some cases hereditary. In its chronic form, this disease may long resist treatment, but it is always in some measure influenced by the diet and regimen and by the occupation of the patient. As a rule persons of sedentary pursuits and brain-workers suffer more from dyspepsia than those leading active lives.

As regards *treatment* only a few general observations can be made. The careful arrangement of the diet is a matter of first importance. Quantity must be regulated by the digestive capabilities of the individual, his age, and the demands made upon his strength by work. There is little doubt that the danger is in most instances on the side of excess, and the rule which enjoins the cessation from eating before the appetite is satisfied is a safe one for dyspeptics. Due time, too, must be given for the digestion of a meal, and from four to six hours are in general required for this purpose. Long fasts, however, are nearly as hurtful as too frequent meals. Of no less importance is the kind of food taken, and on this point those who suffer from indigestion must ever exercise the greatest care. Every article of diet which past experience has proved to disagree should be shunned, since what may appear trifling indiscretions to this respect are often productive of great and prolonged suffering. The tables which have been framed to show the relative digestibility of various kinds of food, and which

have been founded largely on the observations of Dr Beaumont in the celebrated case of Alexis St Martin, are only valuable within certain limits when applied to the treatment of dyspepsia. It must be borne in mind that idiosyncrasy often plays an important part in digestion, some persons being unable to partake without injury of substances which are generally regarded as wholesome and digestible. Difficulty, too, is often experienced in dealing with dyspeptics from their aversion to, or want of appetite for, those forms of diet which appear most suitable for them. Experience has shown that in this complaint no particular kind of food is absolutely to be relied on, but that in general the best diet is one of a mixed animal and vegetable kind simply but well cooked. The partaking of many dishes, of highly seasoned or salted meats, raw vegetables, newly baked bread, pastry, and confectionery, are all well known common causes of dyspepsia, and should be avoided. When even the simple diet usually taken is found to disagree, it may be necessary to change it temporarily for a still lighter form, such as a milk diet, and that even in very moderate quantity.

General hygienic measures are highly important, since whatever improves the state of the health will have a favourable influence on digestion. Hence regular exercise in the open air, early rising, and the cold bath are to be strongly recommended.

The medicinal remedies for dyspepsia are exceedingly numerous, and a few only of them can be mentioned. Attacks brought on by errors in diet are generally relieved by small doses of rhubarb and bismuth, and by the use of small quantities of light and bland food. In chronic dyspepsia the treatment must depend on the cause of the disorder, so far as that can be ascertained. When the dyspepsia is of the atonic form without much irritability of stomach, bitter tonics such as *nux vomica*, *calumba*, *gentian*, or *quassia*, along with some of the mineral acids taken before, with, or immediately after a meal will be found highly serviceable; while on the other hand, when there is gastric irritation with acid eructations, sickness, and pain, the medicinal hydrocyanic acid along with bismuth, and antacids taken after food will often afford relief. Pepsine is a remedy of undoubted value in many cases of dyspepsia, and appears to supply the place of that ingredient of the gastric juice when it is deficient in amount. It may be given along with a meal, alone, or in conjunction with diluted hydrochloric acid, which also is a remedy of great efficacy in indigestion. Strict attention must ever be paid to the regular action of the bowels, and where laxatives are required an aloetic dinner pill, or, what is often better, one of the mineral bitter waters (such as that of Frederickshall) which are now so commonly used, should be had recourse to.

The employment of alcoholic stimulants to assist digestion is largely resorted to both with and without medical advice. While it seems probable that in certain cases of atonic dyspepsia, particularly in the feeble and aged, the moderate administration of alcohol has the effect of stimulating the secretion of gastric juice, and is an important adjuvant to other remedies, the advantages of its habitual use as an aid to digestion by the young and otherwise healthy is more than questionable, and it will generally be found that among them those are least troubled with indigestion who abstain from it. See PHYSIOLOGY and DIETETICS. (J.O.A.)

DYVEKE, in German often *Düveke*, and in the Latin chronicles *Columbella*, the "Little Dove," the name by which the mistress of Christian II. of Denmark is invariably designated. Her father was a certain Sigbrit Villums, who had been obliged for political reasons to leave his native country of Holland. Settling at Bergen, he opened an inn, which soon became known for something more than the hospitality of the host or the excellence of his cheer: his daughter's beauty was bush enough for his weakest wine. Valkendorp, the chancellor, did not think it unbecoming of his priestly character to sound her praise in the ears of the young crown-prince; and accordingly, when he visited Bergen in 1507, the prince made a point of seeing the "Little Dove" for himself. In matters of this sort there is unquestionably a royal road; and so having danced with her at a ball or two, he had little difficulty in getting her to leave the inn for a house of her own at Oslo. She followed him to Copenhagen on his accession in 1513, and both her father and mother obtained unusual influence at court. In 1515 the young king, indeed, was constrained from reasons of state to marry Isabella, the sister of Charles V; but in spite of the emperor's remonstrance, his relations with Dyveke and her parents underwent no real alteration till her sudden death in 1517. That she had been poisoned was the natural verdict of the popular feeling; and the royal suspicion fell on Torben Oxa, warden of the castle of Copenhagen, who was known to have made love to the girl before she was carried off by the prince, and was it not true that two days before her death he had sent her a present of cherries? It mattered not that the culprit was declared innocent by the royal council: "though his neck were as thick as the neck of a bull it should not save his head," raged the king; and he kept his word. Such is the story, not altogether authenticated, which has furnished a favourite theme to dramatist and novelist. Samsoë the Danish poet, published his well-known tragedy "*Dyveke*" in the close of the 18th century, and it was translated by Manthey into German in 1798. Munch treated the subject in a semi-historical manner in his *Biograph-histor. Studien*; Hermann Marggraff's tragedy of *Das Taubchen von Amsterdam* appeared in 1839, Rickhoff's *Düveke* in 1842, Hanch's *Wilhelm Zabern* in 1834, Ida Frick's *Sybrecht Willums* in 1843, and Mosenthal's *Düveke* in 1860.

DZUNGARIA, DSONGARIA, or SONGARIA, a former Mongolian kingdom of Central Asia, raised to its highest pitch by Kaldan or Bushtu Khan in the latter half of the 17th century, but completely destroyed by Chinese invasion about 1757-59. It derived its name from the Dsongars, or Songars, who were so called because they formed the left wing (*dson*, left; *gar*, hand) of the Mongolian army. Its widest limit included Kashgar, Yarkand, Khotan, the whole region of the Thian Shan Mountains, and in short the greater proportion of that part of Central Asia which extends from 35° to 50° N. lat. and from 72° to 97° E. long. The name, however, is more properly applied only to the present Chinese province of Thian-Shan-pe-lu and the country watered by the Il. As a political or geographical term it has practically disappeared from the map; but the range of mountains stretching north-east along the southern frontier of the Land of the Seven Streams—as the district to the south-east of the Balkhash Lake is called—preserves the name of the Dzungarian Range.

E

E is the second vowel-symbol and the fifth letter in our alphabet. In its original form among the Phœnicians it represented the rough breathing—our *h* we have seen that A represented the smooth breathing. As the Greeks had the sound *h* at a very early period, it might have been expected that this symbol would have been taken by them with its original value. But the want of symbols to denote the vowels was apparently felt to be more imperative; therefore all the Phœnician symbols (corresponding to the Hebrew aleph, he, ayin) were taken to denote the vowel-sounds *a*, *e*, *o* respectively. The form of the symbol E has varied little from the earliest Greek times to our own. In old Latin it is sometimes, but rarely, found in the form || The typical sound of E in almost all languages is one of those which we denote generally by *a* in English, *e* *g*, in the word *fate*—that is, one of the simple sounds between A (English *ah*) and I (English *ee*), which are produced by raising the tongue gradually from its lowest position (at A) to its highest position (at I): in this scale of sounds the lips are not employed. The most clearly distinguished of these sounds are (1) that in *men*, (2) that in *fair*, (3) that in *fate*. It will be observed that these sounds have here different symbols; and if these were consistently employed in English we should not have much reason to complain of our spelling; but *e* has also the I-sound in *here* and *see*, *ai* in *vait* has the same sound as *a* in *fate*, and *a* has many sounds. Other languages employ diacritical marks to distinguish these sounds; thus in Italian we have *è* and *é*, called “open” and “close” *e* respectively; these correspond very nearly to (2) and (3) mentioned above. It is probable that the same distinction of sound was given in Latin by employing *ae* to express the open *e* at least open *e* is commonly found in Italian words which were written in Latin with *ae*, or with *e* short. It is possible that in Greece a similar distinction of close open *e* was expressed in early times by the symbols *ε* (epsilon) and *η* (eta); but in Attica, at least after 403 B.C., the distinction seems to have been rather quantitative than qualitative. For the history of *ota* see article H. It is clear that in a perfect alphabet we ought to have at least three distinct symbols between A and I: we ought not to be compelled to distinguish the simple sounds by diphthongs or other modifications. Indeed yet more symbols would be desirable, for there are other sounds in this scale, which, however, are not easily distinguished from the above except by a practised ear.

It is probable that *ee* in English of the 16th and 17th centuries had the sound still heard in Scotland in words like *ell*, *ee*, the simple *e* in our *men* pronounced long—this is not unlike the open *e*, but the back of the tongue is lower. But *ee* had acquired its present I sound in the last century.

EACHARD, JOHN (1636–1697), an English divine, was born in Suffolk in 1636, and was educated at Catherine Hall, Cambridge, of which he became master in 1675 in succession to Lightfoot. He was created a doctor of divinity in 1676 by royal mandate, and was twice (in 1679 and 1695) vice-chancellor of the university. He died on the 7th July 1697. In 1670 he had published anonymously a humorous satire entitled *The Ground and Occasions of the Contempt of the Clergy enquired into in a letter to R. L.*, which excited much attention and provoked several replies, one of them being from John Owen. These were met by *Some Observations, etc., in a second letter to R. L.* (1671), written in the same bantering tone as the

original work. Eachard attributed the contempt into which the clergy had fallen to their imperfect education, their insufficient incomes, and the want of a true vocation. He gave amusing illustrations of the absurdity and poverty of the current pulpit oratory of his day, some of them being taken from the sermons of his own father. He attacked the philosophy of Hobbes in his *Mr Hobbs's State of Nature considered, in a dialogue between Philautus and Timothy* (1672), and in his *Some Opinions of Mr Hobbs considered in a second dialogue* (1673). These were written in their author's chosen vein of light satire, and Dryden praised them as highly effective within their own range. It is noteworthy that Eachard's own sermons were not superior to those he satirized. Swift alludes to him as a signal instance of a successful humorist who entirely failed as a serious writer. A collected edition of his works in three volumes, with a notice of his life, was published in 1774.

EADIE, JOHN (1810–1876), theologian and biblical critic, was born at Alva, in Stirlingshire, on the 9th May 1810. Having manifested unusual ability at school, he was sent to the university of Glasgow, where he passed through the usual curriculum in arts. Immediately afterwards he commenced to study for the ministry at the Divinity Hall of the Secession Church, a dissenting body which, on its union a few years later with the Relief Church, adopted the denomination United Presbyterian. In 1835 he was ordained to the pastoral charge of the Cambridge Street Secession church in Glasgow. Here he speedily attained a position of great eminence and usefulness, and for many years before the close of his life he was generally regarded as the leading representative of his denomination in the city which has always been its stronghold. Though he had little claim to be called eloquent, and his style was often slovenly, he had many of the other qualities that secure the most useful and enduring kind of popularity. As a preacher he was distinguished by invariable good sense, frequent flashes of happy illustration, masculine piety, deep spiritual earnestness, breadth of sympathy both intellectual and emotional, and—most specifically of all—by the power he had in his expository discourses of conveying the best results of biblical criticism in an intelligible form to a general audience. Behind the carelessness and apparent indifference of his manner, it was not difficult to detect the quick sensibility and tender feeling which were eminently characteristic of the man. Though more than once invited to an important charge elsewhere, Dr Eadie refused to leave Glasgow, in which he found a sphere more exactly suited to his pastoral gifts than he could expect in any other place. In 1863 he removed with a portion of his congregation to a new and beautiful church at Lansdowne Crescent, where his influence continued unabated until his death.

From his student days Eadie bore a reputation for extensive, if not profound and accurate, scholarship, which he justified and increased during the earlier years of his ministry to such an extent that in 1843 the church to which he belonged appointed him professor of biblical literature and hermeneutics in its Divinity Hall. He held this appointment along with his ministerial charge till the close of his life, and discharged its duties with an efficiency that was universally acknowledged. While his scholarship was not minute or thorough, he was surpassed by few biblical commentators of his day in range of learning, and by still fewer in the soundness of judgment with which his learning was applied. As a critic he was acute and painstaking;

as an interpreter he was eminently fair-minded. In the professor's chair, as in the pulpit, his strength lay in the tact with which he selected the soundest results of biblical criticism, whether his own or that of others, and presented them in a clear and connected form, with a constant view to their practical bearing. If this last fact gave a non-academic aspect to some portions of his lectures, it rendered them not less interesting and probably not less useful to his auditors. Eadie's merits as a scholar were early acknowledged by the usual honorary university distinctions. He received the degree of LL.D from Glasgow in 1844, and that of D.D. from St Andrews in 1850.

Busily engaged as he was in two distinct offices, either of which might well of itself have employed all his energies, Eadie nevertheless found time for an amount of work in a third sphere, of which the same thing might be said. His labours as an author would have been more than creditable to one who had no other occupation. Most of his works were connected with biblical criticism and interpretation, some of them being designed for popular use and others being more strictly scientific. To the former class belong the *Biblical Cyclopædia*, his edition of *Cruden's Concordance*, his *Early Oriental History*, and his discourses on *The Divine Love* and on *Paul the Preacher*, to the latter belong his commentaries on the Greek text of St Paul's epistles to the Ephesians, Colossians, Philippians, and Galatians, published at intervals in four volumes, which take a high rank among exegetical works. His *Life of Dr Kitto* obtained a deserved popularity. His last work, the *History of the English Bible* (2 vols. 1876), will probably be the most enduring memorial of his ability as an author. Though not unimpeachable in point of arrangement and style, it contains a fuller and more accurate account of the subject than is to be found anywhere else, and almost every page bears marks of the life-long interest and loving research of the author. His almost unrivalled knowledge of the various English versions, as well as his ability as a critic and interpreter of the original, led to his being selected as one of the company for the revision of the authorized version of the New Testament, and in this capacity it is understood that he rendered excellent service. Dr Eadie died at Glasgow on the 3d June 1876.

EADMER, or EDMER (in Latin Eadmerus, and by mistake Edmerus and Edinerus), an English ecclesiastic and historian of the Norman period, probably, as his name suggests, of English as opposed to Norman parentage. At an early age he was sent to the Benedictine monastery at Canterbury; and there he became acquainted with Anselm, at the time of the latter's first visit to England as abbot of Bec. The intimacy was renewed when Anselm was raised to the episcopal see; and thenceforward Eadmer was not so much the archbishop's disciple and follower as his friend and director, and that at last not only by Anselm's private recognition, but by the formal appointment of Pope Urban II. So complete, indeed, was the obedience shown by the great scholastic philosopher and head of the English Church to his self-elected tutor, that—according to William of Malmesbury, *De gestis pontificum Anglorum*, lib. i.—he is said to have waited for his express permission before he rose from his bed, or even turned from one side to the other. After Anselm's death Eadmer accompanied Radulph, the new archbishop, to Rome in 1119; and on their return in 1120 he was nominated to the see of St Andrews in Scotland. Owing, however, to the refusal of the Scotch to recognize the claims put forward by Eadmer and his patron in support of the episcopal authority of the see of Canterbury, he was never formally inducted into the office. He was at Canterbury in 1121, and he spent the latter part of his life as prior of the monastery there. His death is variously assigned to the year 1123 and 1137.

Eadmer has left a large number of works, of which a list is given in Wharton's *Anglia Sacra*, part ii. Most important are his *Historia Novorum*, in six books treating of his own times down to the death of Radulph in 1122, and his *Vita Anselmi*, which ranks as one of the chief authorities in regard to the primate. The former was first published by Selden in 1623, the latter at Antwerp in 1551; and both have since been several times reprinted. Of less mark are his lives of Odo, Bregwin, and Duustan, and of Oswald and Wilfrid of York, and his treatises—formerly ascribed to Anselm—*De quatuor virtutibus quæ fuerunt in beata Maria virgine*, and *De similitudinibus S. Anselmi*. Nearly all his works are to be found in an early MS. in the library of Corpus Christi College, Cambridge (C C C C, No 371), and most of them have been reprinted as an appendix to Anselm's *Opera* by Gerberon, fol. 1676, and by the Benedictine monks of St Maure, fol. Paris, 1721. A number of his letters are preserved in MSS Cotton, Otho, A xi. See especially Wright, *Biographia Brit Lit.*, Anglo-Norman Period, 1846, Chama, *Saint Anselm*, 1863, pp 186, 187, Burton, *History of Scotland*, vol. i. pp 422-424.

EAGLE (French *Aigle*, from the Latin *Aquila*), the name generally given to the larger Diurnal Birds-of-prey which are not Vultures; but the limits of the subfamily *Aquilinæ* have been very variously assigned by different writers on systematic ornithology, and, as before observed (BJZZARD, vol. iv. p. 603), there are Eagles smaller than certain Buzzards. By some authorities the *Lammergeier* of the Alps, and other high mountains of Europe, North Africa, and Asia, is accounted an Eagle, but by others the genus *Gypætus* is placed with the *Fulviniæ*, as its common English name (Bearded Vulture) shows. There are also other forms, such as the South-American *Harpyia* and its allies, which though generally called Eagles have been ranked as Buzzards. In the absence of any truly scientific definition of the family *Aquilinæ* it is best to leave these and many other more or less questionable members of the group—such as the genera *Spizæetus*, *Circæetus*, *Spilornis*, *Hælotarsus*, and so forth—and, so far as space will allow, to treat here of those whose position cannot be gainsaid.

True Eagles inhabit all the Regions of the world, and some seven or eight species at least are found in Europe, of which two are resident in the British Islands. In England and in the Lowlands of Scotland Eagles only exist as stragglers; but in the Hebrides and some parts of the Highlands a good many may yet be found, and their numbers appear to have rather increased of late years than diminished; for the foresters and shepherds, finding that a high price can be got for their eggs, take care to protect the owners of the eyries, which are nearly all well known, and to keep up the stock by allowing them at times to rear their young. There are also now not a few occupiers of Scottish forests who interfere so far as they can to protect the king of birds. But hardly twenty years ago trapping, poisoning, and other destructive devices were resorted to without stint, and there was then every probability that before long not an Eagle would be left to add the wild majesty of its appearance to the associations of the mountain or the lake.¹ In Ireland the extirpation of Eagles seems to have been carried on almost unaffected by the prudent considerations which in the northern kingdom have operated so favourably for the race, and except in the wildest parts of Donegal, Mayo, and Kerry, Eagles in the sister-island are said to be almost birds of the past.

Of the two British species the Erne, (Icel. *Ænu*) or Sea-

¹ The late Lord Breadalbane was perhaps the first large landowner who set the example that has been since followed by others. On his unrivalled forest of Black Mount, Eagles—elsewhere persecuted to the death—were by him ordered to be unmolested so long as they were not numerous enough to cause considerable depredations on the farmers' flocks. He thought, and all who have an eye for the harmonies of nature will agree with him, that the spectacle of a soaring Eagle was a fitting adjunct to the grandeur of his Argyllshire mountain-scenery, and a good equivalent for the occasional loss of a lamb, or the slight deduction from the rent paid by his tenantry in consequence. How faithfully his wishes were carried out by his head-forester, Mr Peter Robertson, the present writer has abundant means of knowing.

Eagle (by some called also the White-tailed and Cmereous Eagle)—*Haliaeetus albicilla*—affects chiefly the coast and neighbourhood of inland waters, living in great part on the fish and refuse that is thrown up on the shore, though it not unfrequently takes living prey, such as lambs, hares, and rabbits. On these last, indeed, young examples mostly feed when they wander southward in autumn, as they

shire, is well described by Willughby, in whose time it was said to breed also in the Snowdon range. It seldom if ever frequents the coast, and is more active on the wing than the Sea-Eagle, being able to take some birds as they fly, but a large part of its sustenance is the flesh of animals that die a natural death. Its eyry is generally placed and built like that of the other British species,¹ but the

FIG 1—Sea-Eagle.

yearly do, and appear in England. The adults (fig. 1) are distinguished by their prevalent greyish-brown colour, their pale head, yellow beak, and white tail—characters, however, wanting in the immature, which do not assume the perfect plumage for some three or four years. The eyry is commonly placed in a high cliff or on an island in a lake—sometimes on the ground, at others in a tree—and consists of a vast mass of sticks, in the midst of which is formed a hollow lined with *Luzula sylvatica* (as first observed by the late Mr John Wolley) or some similar grass, and here are laid the two or three white eggs. In former days the Sea-Eagle seems to have bred in several parts of England—as the Lake district, and possibly even in the Isle of Wight and on Dartmoor. This species inhabits all the northern part of the Old World from Iceland to Kamchatka, and breeds in Europe so far to the southward as Albania. In the New World, however, it is only found in Greenland, being elsewhere replaced by the White-headed or Bald Eagle, *H. leucocephalus*, a bird of similar habits, and the chosen emblem of the United States of America. In the far east of Asia occurs a still larger and finer Sea-Eagle, *H. pelagicus*, remarkable for its white thighs and upper wing-coverts. South-eastern Europe and India furnish a much smaller species, *H. leucorhynchus*, which has its representative, *H. leucogaster*, in the Malay Archipelago and Australia, and, as allies in South Africa and Madagascar, *H. vocifer* and *H. vociferoides* respectively. All these Eagles may be distinguished by their scaly tarsi, while the group next to be treated of have the tarsi feathered to the toes.

The Golden or Mountain-Eagle, *Aquila chrysaetos*, is the second British species. This also formerly inhabited England, and a nest, found in 1668 in the Peak of Derby-

FIG 2—Golden Eagle

neighbourhood of water is not requisite. The eggs, from two to four in number, vary from a pure white to a mottled, and often highly-coloured, surface, on which appear different shades of red and purple. The adult bird (fig. 2) is of a rich, dark brown, with the elongated feathers of the neck, especially on the nape, light tawny, in which imagination sees a "golden" hue, and the tail marbled with brown and ashy-grey. In the young the tail is white at the base, and the neck has scarcely any tawny tint. The Golden Eagle does not occur in Iceland, but occupies suitable situations over the rest of the Palearctic Region and a considerable portion of the Nearctic—though the American bird has been, by some, considered a distinct species. Domesticated, it has many times been trained to take prey for its master in Europe, and to this species is thought to belong an Eagle habitually used by the Kirgiz Tartars, who call it *Bergut* or *Bearcoat*, for the capture of antelopes, foxes, and wolves. It is carried hooded on horseback or on a perch between two men, and released when the quarry is in sight. Such a bird, when well trained, is valued, says Pallas, at the price of two camels. It is quite possible, however, that more than one kind of Eagle is thus used, and the services of *A. heliaca* (which is the Imperial Eagle of some writers²) and of *A. mogilnik*—

¹ As already stated, the site chosen varies greatly. Occasionally placed in a niche in what passes for a perpendicular cliff to which access could only be gained by a skilful cragsman with a rope, the writer has known a nest to within ten or fifteen yards of which he rode on a pony. Two beautiful views of as many Golden Eagle's nests, drawn on the spot by Mr Wolf, are given in the *Ootheca Hotteliana*, and a fine series of eggs is also figured in the same work.

² Which species may have been the traditional emblem of Roman power, and the *Ales Jovis*, is very uncertain.

both of which are found in Central Asia, as well as in South-eastern Europe—may also be employed

Of the other more or less nearly allied species or races want of room forbids the consideration, but there is a smaller form on which a few words may be said. This has usually gone under the name of *A. nana*, but is now thought by the best authorities to include three local races, or, in the eyes of some, species. They inhabit Europe, North Africa, and Western Asia to India, and two examples of one of them—*A. clanga*, the form which is somewhat plentiful in North-eastern Germany—have occurred in Cornwall. The smallest true Eagle is *A. pennata*, which inhabits Southern Europe, Africa, and India. Differing from other Eagles of their genus by its wedge-shaped tail, though otherwise greatly resembling them, is the *A. audax* of Australia. Lastly may be noticed here a small group of Eagles, characterized by their long legs, forming the genus *Nisaetus*, of which one species, *N. fasciatus*, is found in Europe. The Osprey (*Pandion*), though placed by many among the *Aquilinae*, certainly does not belong to that subfamily. (A. N.)

EAR The simplest form of the organ of hearing is a small sac containing fluid, with the auditory nerve expanded upon it. Sonorous vibrations are communicated to this sac either directly through the hard parts of the head, or at the same time by a membrane exposed to the surrounding medium. Such is the form of ear found in many of the Crustacea and in the Cephalopoda. In the Vertebrata, there is a progressive development and increasing complexity from the fishes up to Mammalia. For details as to the structure of the ear in the different subdivisions of the Vertebrata, reference is made to the articles treating of these, such as AMPHIBIA, BIRDS, &c.; and the structure of the human ear will be found fully described in the article ANATOMY, vol. i. p. 891. It is the object of this article to describe the phenomena of auditory sensation from the physiological point of view.

The sense of hearing is a special sensation the cause of which is an excitation of the auditory nerves by the vibrations of sonorous bodies. A description of sonorous vibrations and of their transmission is given in the article ACOUSTICS, here we shall consider, first, the transmission of such vibrations from the external ear to the auditory nerve, and secondly, the physiological characters of auditory sensation.

I.—1. Transmission in External Ear.—The external ear consists of the *pinna*, or auricle, and the *external auditory meatus*, or canal, at the bottom of which we find the *membrana tympani*, or drum head. In many animals the auricle is trumpet-shaped, and, being freely movable by muscles, serves to collect sonorous waves coming from various directions. The auricle of the human ear presents many irregularities of surface. If these irregularities are abolished by filling them up with a soft material such as wax or oil, leaving the entrance to the canal free, experiment shows that the intensity of sounds is weakened, and that there is more difficulty in judging of their direction. When waves of sound strike the auricle, they are partly reflected outwards, while the remainder, impinging at various angles, undergo a number of reflections so as to be directed into the auditory canal. Vibrations are transmitted along the auditory canal, partly by the air it contains and partly by its walls, to the *membrana tympani*. The absence of the auricle, as the result of accident or injury, has not caused diminution of hearing. In the auditory canal, waves of sound are reflected from side to side until they reach the *membrana tympani*. From the obliquity in position and peculiar curvature of this membrane, most of the waves must strike it nearly perpendicularly, and in the most advantageous direction.

2 Transmission in Middle Ear.—The middle ear is a small cavity, the walls of which are rigid with the exception of the portions consisting of the *membrana tympani*, and the membrane of the round window and of the apparatus filling the oval window. This cavity communicates with the pharynx by the *Eustachian tube*, which forms a kind of air-tube between the pharynx and the tympanum for the purpose of regulating pressure on the *membrana tympani*. It is generally supposed that during rest the tube is open, and that it is closed during the act of deglutition. As this action is frequently taking place, not only when food or drink is introduced, but when saliva is swallowed, it is evident that the pressure of the air in the tympanum will be kept in a state of equilibrium with that of the external air on the outer surface of the *membrana tympani*, and that thus the *membrana tympani* will be rendered independent of variations of atmospheric pressure such as may occur within certain limits, as when we descend in a diving bell or ascend in a balloon. By a forcible expiration, the oral and nasal cavities being closed, air may be driven into the tympanum, while a forcible inspiration (Valsalva's experiment) will draw air from that cavity. In the first case, the *membrana tympani* will bulge outwards, in the second case inwards, and in both, from excessive stretching of the membrane, there will be partial deafness, especially for sounds of high pitch. Permanent occlusion of the tube is one of the most common causes of deafness.

The *membrana tympani* is capable of being set into vibration by a sound of any pitch included in the range of perceptible sounds. It responds exactly as to number of vibrations (pitch), intensity of vibrations (intensity), and complexity of vibration (quality or timbre). Consequently we can hear a sound of any given pitch, of a certain intensity, and in its own specific timbre or quality. Generally speaking, very high tones are heard more easily than low tones of the same intensity. As the *membrana tympani* is not only fixed by its margin to a ring or tube of bone, but is also adherent to the handle of the malleus, which follows its movements, its vibrations meet with considerable resistance. This diminishes the intensity of its vibrations, and prevents also the continued vibration of the membrane after an external vibration has ceased, so that a sound is not heard much longer than it lasts. The tension of the membrane may be affected (1) by differences of pressure on the two surfaces of the *membrana tympani*, as may occur during forcible expiration or inspiration, or in a pathological condition, and (2) by muscular action, due to contraction of the *tensor tympani* muscle. This small muscle arises from the apex of the petrous temporal and the cartilage of the Eustachian tube, enters the tympanum at its anterior wall, and is inserted into the malleus near its root. The handle of the malleus is inserted between the layers of the *membrana tympani*, and, as the malleus and incus move round an axis passing through the neck of the malleus from before backwards, the action of the muscle is to pull the *membrana tympani* inwards towards the tympanic cavity in the form of a cone, the meridians of which, according to Helmholtz, are not straight but curved, with convexity outwards. When the muscle contracts, the handle of the malleus is drawn still farther inwards, and thus a greater tension of the tympanic membrane is produced. On relaxation of the muscle, the membrane returns to its position of equilibrium by its own elasticity and by the elasticity of the chain of bones. This power of varying the tension of the membrane is a kind of accommodating mechanism for receiving and transmitting sounds of different pitch. With different degrees of tension, it will respond more readily to sounds of different pitch. Thus, when the membrane is tense, it will readily respond to high sounds, while relaxation will be the condition most

adapted for low sounds. In addition, increased tension of the membrane, by increasing the resistance, will diminish the intensity of vibrations. This is especially the case for sounds of low pitch.

Helmholtz has also pointed out that the peculiar form of the membrana tympani in man has the effect of increasing the force of its vibrations at the expense of their amplitude.

The vibrations of the membrana tympani are transmitted to the internal ear partly by the air which the middle ear or tympanum contains, and partly by the chain of bones, consisting of the malleus, incus, and stapes. Of these, transmission by the chain of bones is by far the most important. In birds and in the scaly amphibia, this chain is represented by a single rod-like ossicle, the *columella*, but in man the two membranes—the membrana tympani and the membrane filling the fenestra ovalis—are connected by a compound lever consisting of three bones, namely, the *malleus*, or hammer, inserted into the membrana tympani, the *incus*, or anvil, and the *stapes*, or stirrup, the base of which fits into the oval window. The lever thus formed has its fulcrum near the short process of the incus, which abuts against the tympanic wall; the power is applied at the handle of the malleus, and the resistance is at the base of the stirrup. Both by direct experimental observation and by calculation from data supplied by measurement of the lengths of the arms of the lever, Helmholtz has shown that by this arrangement vibrations are diminished in extent in the ratio of 3 to 2, but are inversely increased in force. Considering the great resistance offered to excursions of the stapes, such an arrangement must be advantageous. It must also be noted that in the transmission of vibrations of the membrana tympani to the fluid in the labyrinth or internal ear, through the oval window, the chain of ossicles vibrates as a whole and acts efficiently, although its length may be only a small fraction of the wave length of the sound transmitted.

3. *Transmission in the Internal Ear.*—The internal ear is composed of the labyrinth, formed of the vestibule or central part, the semicircular canals, and the cochlea, each of which consists of an osseous and a membranous portion (see vol. i. p. 893). The osseous labyrinth may be regarded as an osseous mould in the petrous portion of the temporal bone, lined by tessellated endothelium, and containing a small quantity of fluid called the *perilymph*. In this mould, partially surrounded by, and to some extent floating in, this fluid, there is the membranous labyrinth, in certain parts of which we find the terminal apparatus in connection with the auditory nerve, immersed in another fluid called the *endolymph*. The membranous labyrinth consists of a vestibular portion formed by two small sac-like dilatations, called the *saccul*e and the *utricle*, the latter of which communicates with the semicircular canals by five openings. Each canal consists of a tube, bulging out at each extremity so as to form the so-called *ampulla*, in which, on a projecting ridge, called the *crusta acoustica*, there are cells bearing or developed into long *auditory hairs*, which are to be regarded as the peripheral end-organs of the vestibular branches of the auditory nerve. The cochlear division of the membranous labyrinth consists of the *ductus cochlearis*, a tube of triangular form fitting in between the two cavities in the cochlea, called the *scala vestibuli*, because it commences in the vestibule, and the *scala tympani*, because it ends in the tympanum, at the round window. These two *scalæ* communicate at the apex of the cochlea. The roof of the ductus cochlearis is formed by a thin membrane called the *membrane of Reissner*, while its floor consists of the *basilar membrane*, on which we find the remarkable *organ of Corti*, which constitutes the terminal organ of the cochlear division of the auditory

nerve, and which is fully described in vol. i. p. 894. It is sufficient to state here that this organ consists essentially of an arrangement of epithelial cells bearing hairs which are in communication with the terminal filaments of this portion of the auditory nerve, and that groups of these hairs pass through holes in a closely investing membrane, *membrana reticularis*, which may be supposed to act as a damping apparatus, so as quickly to stop their movements. The ductus cochlearis and the two *scalæ* are filled with fluid. Sonorous vibrations may reach the fluid in the labyrinth by three different ways—(1) by the osseous walls of the labyrinth, (2) by the air in the tympanum and the round window, and (3) by the base of the stapes inserted into the oval window.

When the head is plunged into water, or brought into direct contact with any vibrating body, vibrations must be transmitted directly. Vibrations of the air in the mouth and in the nasal passages are also communicated directly to the walls of the cranium, and thus pass to the labyrinth. In like manner, we may experience peculiar auditive sensations, such as blowing, rubbing, and hissing sounds, due to muscular contraction or to the passage of blood in vessels close to the auditory organ. It has not been satisfactorily made out to what extent, if any, vibrations may be communicated to the fluid in the labyrinth by the round window. There can be no doubt, however, that in ordinary hearing vibrations are communicated chiefly by the chain of bones. When the base of the stirrup is pushed into the oval window, the pressure in the labyrinth increases, the impulse passes along the *scala vestibuli* to the *scala tympani*, and, as the only mobile part of the wall of the labyrinth is the membrane covering the round window, this membrane is forced outwards; when the base of the stirrup passes outwards, a reverse action takes place. Thus the fluid of the labyrinth may receive a series of pulses or vibrations isochronous with the movements of the base of the stirrup, and these pulses affect the terminal apparatus in connection with the auditory nerve.

Since the size of the membranous labyrinth is so small, measuring, in man, not more than $\frac{1}{2}$ inch in length by $\frac{1}{16}$ inch in diameter at its widest part, and since it is a chamber consisting partly of conduits of very irregular form, it is impossible to state accurately the course of vibrations transmitted to it by impulses communicated from the base of the stirrup. In the cochlea, vibrations must pass from the saccul along the *scala vestibuli* to the apex, thus affecting the membrane of Reissner, which forms its roof, then, passing through the opening at the apex (the *helicotrema*), they must descend by the *scala tympani* to the round window, and affect in their passage the *membrana basilaris*, on which the organ of Corti is situated. From the round window impulses must be reflected backwards, but how they affect the advancing impulses is not known. But the problem is even more complex when we take into account the fact that impulses are transmitted simultaneously to the utricle and to the semicircular canals communicating with it by five openings. The mode of action of these vibrations or impulses upon the nervous terminations is still unknown; but to appreciate critically the hypothesis which has been advanced to explain it, it is necessary, in the first place, to refer to some of the general characters of auditory sensation.

4. Certain conditions are necessary for excitation of the auditory nerve sufficient to produce a sensation. In the first place, the vibrations must have a certain amplitude: if too feeble, no impression will be produced. The minimum limit has been stated to be the sensation caused by the falling of a ball of pith, 1 milligramme in weight, upon a smooth surface, such as glass, from a height of 1 millimetre at a distance of 91 millimetres from the ear.

In the next place, vibrations must have a certain duration to be perceived; and lastly, to excite a sensation of a continuous musical sound, a certain number of vibrations must occur in a given interval of time. The lower limit is about 30, and the upper about 30,000 vibrations per second. Below 30, the individual impulses may be observed, and above 30,000 few ears can detect any sound at all. The extreme upper limit is not more than 35,000 vibrations per second. Auditory sensations are of two kinds—noises and musical sounds. *Noises* are caused by impulses which are not regular in intensity or duration, or are not periodic, or they may be caused by a series of musical sounds occurring instantaneously so as to produce disorders, as when we place our hand at random on the key-board of a piano. *Musical tones* are produced by periodic and regular vibrations. In musical sounds three characters are prominent—intensity, pitch, and quality. *Intensity* depends on the amplitude of the vibration, and a greater or lesser amplitude of the vibration will cause a corresponding movement of the transmitting apparatus, and a corresponding intensity of excitation of the terminal apparatus. *Pitch*, as a sensation, depends on the length of time in which a single vibration is executed, or, in other words, the number of vibrations in a given interval of time. The ear is capable of appreciating the relative pitch or height of a sound as compared with another, although it may not ascertain precisely the absolute height of a sound. What we call an acute or high tone is produced by a large number of vibrations, while a grave or low tone is caused by few. The musical tones which can be used with advantage range between 40 and 4000 vibrations per second, extending thus from 6 to 7 octaves. According to E. H. Wober, practised musicians can perceive a difference of pitch amounting even to only the $\frac{1}{16}$ th of a semitone, but this is far beyond average attainment. *Quality or timbre* (or *Klang*) is that peculiar characteristic of a musical sound by which we may identify it as proceeding from a particular instrument or from a particular human voice. It depends on the fact that many waves of sound that reach the ear are really compound wave systems, built up of constituent waves, each of which is capable of exciting a sensation of a simple tone if it be singled out and reinforced by a resonator (see *ACOUSTICS*), and which may sometimes be heard without a resonator, after special practice and tuition. Thus it appears that the ear must have some arrangement by which it resolves every wave system, however complex, into simple pendular vibrations. When we listen to a sound of any quality we recognize that it is of a certain pitch. This depends on the number of vibrations of one tone, predominant in intensity over the others, called the fundamental or ground tone, or first partial tone. The quality, or timbre, depends on the number and intensity of other tones added to it. These are termed *harmonic* or *partial tones*, and they are related to the first partial or fundamental tone in a very simple manner, being multiples of the fundamental tone: thus—

	Funda- mental Tone.	Upper Partial or Harmonics.									
Notes..	do ¹	do ²	sol ²	do ³	mi ³	sol ³	si ³	do ⁴	re ⁴	mi ⁴	
Partial tones .	1	2	3	4	5	6	7	8	9	10	
Number of } vibrations }	33	66	99	132	165	198	231	264	297	330	

When a simple tone, or one free from partials, is heard, it gives rise to a simple, soft, somewhat insipid sensation, as may be obtained by blowing across the mouth of an open bottle or by a tuning fork. The lower partials added to the fundamental tone give softness combined with richness; while the higher, especially if they be very high, produce a brilliant and thrilling effect, as is caused by the brass instruments of an orchestra. Such being the facts, how may they be explained physiologically?

Little is yet known regarding the mode of action of the vibrations of the fluid in the labyrinth upon the terminal apparatus connected with the auditory nerve. There can be no doubt that it is a mechanical action, a true communication of impulses to delicate hair-like processes, by the movements of which the nervous filaments are irritated. In the human ear it has been estimated that there are about 3000 small arches formed by the *rods of Corti* (see *ANATOMY*). Each arch rests on the basilar membrane, and supports rows of cells having minute hair-like processes somewhat resembling cilia. It would appear also that the filaments of the auditory nerve terminate in the basilar membrane, and possibly they may be connected with the hair-cells. At one time it was supposed by Helmholtz that these fibres of Corti were elastic and that they were tuned for particular sounds, so as to form a regular series corresponding to all the tones audible to the human ear. Thus 2800 fibres distributed over the tones of seven octaves would give 400 fibres for each octave, or nearly 33 for a semitone. Helmholtz has put forward the ingenious hypothesis that, when a pendular vibration reaches the ear, it excites by sympathetic vibration the fibre of Corti which is tuned for its proper number of vibrations. If, then, different fibres are tuned to tones of different pitch, it is evident that we have here a mechanism which, by exciting different nerve fibres, will give rise to sensations of pitch. When the vibration is not simple but compound, in consequence of the blending of vibrations corresponding to various harmonics or partial tones, the ear has the power of resolving this compound vibration into its elements. It can only do so by different fibres responding to the constituent vibrations of the sound,—one for the fundamental tone being stronger, and giving the sensation of a particular pitch or height to the sound, and the others, corresponding to the upper partial tones, being weaker, and causing special though undefined sensations, which are so blended together in consciousness as to terminate in a complex sensation of a tone of a certain quality or timbre. It would appear at first sight that 33 fibres of Corti for a semitone are not sufficient to enable us to detect all the gradations of pitch in that interval, since, as has been stated above, trained musicians may distinguish a difference of $\frac{1}{16}$ th of a semitone. To meet this difficulty, Helmholtz states that if a sound is produced, the pitch of which may be supposed to come between two adjacent fibres of Corti, both of these will be set into sympathetic vibration, but the one which comes nearest to the pitch of the sound will vibrate with greater intensity than the other, and that consequently the pitch of that sound would be thus appreciated. These theoretical views of Helmholtz have derived much support from remarkable experiments of Hensen, who observed that certain hairs on the antennæ of *Mysis*, a Crustacean, when observed with a low microscopic power, vibrated with certain tones produced by a keyed horn. It was seen that certain tones of the horn set some hairs into strong vibration, and other tones other hairs. Each hair responded also to several tones of the horn. Thus one hair responded strongly to *d*[#] and *d*[#], more weakly to *g*, and very weakly to *a*. It was probably tuned to some pitch between *d*[#] and *d*[#]. (*Studien über das Gehörorgan der Decapoden*, Leipzig, 1863.)

Recent histological researches have led to a modification of this hypothesis. It has been found that the rods or arches of Corti are stiff structures, not adapted for vibrating, but apparently consisting of a kind of support for the hair cells. It is also known that there are no rods of Corti in the cochlea of birds, which apparently are capable nevertheless of appreciating pitch. Hensen and Helmholtz have now suggested the view that not only may the segments of the membrana basilaris be stretched more in the radial than

in the longitudinal direction, but different segments may be stretched radially with different degrees of tension so as to resemble a series of tense strings of gradually increasing length. Each string would then respond to a vibration of a particular pitch communicated to it by the hair-cells. The exact mechanism of the hair-cells and of the membrana reticularis, which looks like a damping apparatus, is unknown.

II. *Physiological Characters of Auditory Sensation.*—1. Under ordinary circumstances auditory sensations are referred to the outer world. When we hear a sound, we associate it with some external cause, and it appears to originate in a particular place, or to come in a particular direction. This feeling of *exteriority* of sound seems to require transmission through the membrana tympani. Sounds which are sent through the walls of the cranium, as when the head is immersed in, and the external auditory canals are filled with, water, appear to originate in the body itself. It is probable, however, that the external character of ordinary auditory sensations may be more the result of habit than due to any anatomical peculiarity of the ear itself.

2. An auditory sensation lasts a short time after the cessation of the exciting cause, so that a number of separate vibrations, each capable of exciting a distinct sensation if heard alone, may succeed each other so rapidly that they are fused into a single sensation. If we listen to the puffs of a syren, or to vibrating tongues of low pitch, the single sensation is usually produced by about 30 or 35 vibrations per second, but there can be no doubt, as was first pointed out by Helmholtz, that when we listen to beats of considerable intensity, produced by two adjacent tones of sufficiently high pitch, the ear may follow as many as 132 intermissions per second.

3. The sensibility of the ear for sounds of different pitch is not the same. It is more sensitive for acute than for grave sounds, and it is probable that the maximum degree of acuteness is for sounds produced by about 3000 vibrations per second, that is near fa^{\sharp} . Sensibility as to pitch varies much with the individual and with the training to which he has subjected himself. Thus some musicians may detect a difference of $\frac{1}{1000}$ th of the total number of vibrations, while other persons may have difficulty in appreciating a semitone. This power of appreciating differences of pitch is termed a correct or just ear, and there can be no doubt of its improvement by cultivation.

4. Hearing with two ears does not appear materially to influence auditive sensation, but probably the two organs are enabled, not only to correct each other's errors, but also to aid us in determining the locality from whence a sound originates. It is asserted by Fechner that one ear may perceive the same tone at a slightly higher pitch than the other, but this may probably be due to some slight pathological condition in one ear. If two tones, produced by two tuning forks of equal pitch, are produced one near each ear, there is a uniform single sensation; if one of the tuning forks be made to revolve round its axis in such a way that its tone increases and diminishes in intensity, neither fork is heard continuously, but both sound alternately, the fixed one being only audible when the revolving one is not. It is difficult to decide whether excitations of corresponding elements in the two ears can be distinguished from each other. It is probable that the resulting sensations may be distinguished, provided one of the generating tones differs from the other in intensity or quality, although it may be the same in pitch.

5. Hitherto we have considered only the audition of a single sound, but it is possible also to have simultaneous auditive sensations, as in musical harmony. It is difficult to ascertain what is the limit beyond which distinct auditory

sensations may be perceived. We have in listening to an orchestra a multiplicity of sensations which produces a total effect, while, at the same time, we can with ease single out and notice attentively the tones of one or two special instruments. Thus the pleasure of music may arise partly from listening to simultaneous, and partly from the effect of contrast or suggestion in passing through successive, auditory sensations.

The principles of harmony belong to the subject of music, but it is necessary here briefly to refer to these from the physiological point of view. If two musical sounds reach the ear at the same moment, an agreeable or disagreeable sensation is experienced, which may be termed a *concord* or a *discord*, and it can be shown by experiment with the syren (see ACOUSTICS) that this depends upon the vibrational numbers of the two tones. The octave (1 2), the twelfth (1 3), and double octave (1 4), are absolutely consonant sounds, the fifth (2 3) is said to be perfectly consonant, then follow, in the direction of dissonance, the fourth (3 4), major sixth (3 5), major third (4 5), minor sixth (5 8), and the minor third (5 6). Helmholtz has attempted to account for this by the application of his theory of *beats*.

Beats are observed when two sounds of nearly the same pitch are produced together, and the number of beats per second is equal to the difference of the number of vibrations of the two sounds. Beats give rise to a peculiarly disagreeable intermittent sensation, comparable to what is experienced on watching a flickering light, and the painful sensation may arise from intermittent irritation of the auditory nerve filaments. The maximum roughness of beats, according to Helmholtz, is attained by 33 per second; beyond 132 per second, the individual impulses are blended into one uniform auditory sensation. When two notes are sounded, say on a piano, not only may the first, fundamental, or prime tones beat, but partial tones of each of the primaries may beat also, and as the difference of pitch of two simultaneous sounds augments, the number of beats, both of prime tones and of harmonics, augments also. The physiological effect of beats, though these may not be individually distinguishable, is to give roughness to the ear. If harmonics or partial tones of prime tones coincide, there are no beats, if they do not coincide, the beats produced will give a character of roughness to the interval. Thus in the octave and twelfth, all the partial tones of the acute sound coincide with the partial tones of the grave sound, in the fourth, major sixth, and major third, only two pairs of the partial tones coincide, while in the minor sixth, minor third, and minor seventh, only one pair of the harmonics coincide. For details, see Helmholtz, *On Sensations of Tone as a Physiological Basis for the Theory of Music*, translated by Alexander J. Ellis, London, 1875.

DISEASES OF THE EAR.—Deafness may arise from obstruction of the external ear occasioned by disease of various kinds, from ulceration, thickening, or perforation of the membrana tympani; from inflammatory affections, both acute and chronic, of the middle and internal ear, from obstruction of the Eustachian tube caused by inflammation of its lining membrane, leading to thickening and accumulation of mucus or pus, from diseases of the throat blocking up the end of the Eustachian tube, and, lastly, from disease of the auditory nerve or of the terminal apparatus connected with it in the membranous labyrinth. *Otitis*, or ear-ache, is an inflammation, usually of a rheumatic nature, of some portion of the external auditory canal. Most frequently occurring in weakly individuals, it causes intense pain, which shoots over the head on the affected side. It may lead to the formation of a small abscess in one of the wax glands found in the passage. Hot applications by fomentations or warm poultices give relief, and if an abscess forms, it ought to be carefully lanced. *Otorrhœa* is a muco-purulent discharge, often of a fœtid odour, from the ears of scrofulous children. It frequently occurs during teething, and it may be one of the sequelæ of scarlet fever, or measles, or small-pox. When pus flows from the ear, it may come from the membrane lining the deeper portion of the external meatus, or from the middle ear by a hole in the membrana tympani, or from diseased portions of bone near the middle, or internal ear. The treatment, of course, varies according to the cause, but generally the discharge may be lessened in quantity, and at all events rendered less offensive, by the use of weak in-

jections of carbohc acid or of Condyl's fluid. *Concretions*, consisting of accumulations of wax, often hard and adherent, may block up the external meatus. Frequently these may not impair the sense of hearing, but they give rise to distressing noises of various kinds. They may be got rid of by the careful use of injections of soap and hot water. *Polypti*, usually hard and firm, but sometimes soft and gelatinous, occur in the external meatus. The external ear may become hypertrophied, as in idiots; it may contain concretions of urate of soda, as in gout; and it may be the seat of fibrous tumours. In the insane, large tumours, filled with blood, termed *hematoma*, sometimes occur. One of the most common causes of deafness in children is chronic enlargement of the tonsils from repeated quinsies or from a strumous habit. Frequently also the Eustachian tube is occluded, but by passing a delicate catheter along the tube, and sometimes by inflating artificially the tympanum with air, hearing may be restored. It is difficult to diagnose, and still more difficult to treat, diseases of the internal ear, in consequence of its delicacy of structure and inaccessible situation. Pathological states of the internal ear may give rise to distressing *entotic* phenomena, such as whizzing, buzzing, hissing, blowing, or clanging sounds; and if they are not relieved by washing out the external ear, or by inflating the middle ear by the Eustachian tube, or by counter-irritation by means of small blisters or the application of tincture of iodine behind the ears, nothing more can be done.

(J. G. M.)

EARL (Latin, *comes*; French, *compte*), a title and rank of nobility now the third in the order of the British peerage, and, accordingly, intervening between marquis and viscount. Earl, however, was the highest title and rank of the English nobles *post conquestum* until the year 1337, when by Edward III. the Black Prince was created duke of Cornwall. The "earl" of England was identical with *comite* or *compte* of France; and, so long as Norman-French continued to be spoken in this country, the English "earls" were styled "counts" as well in England as on the Continent. These powerful barons represented and succeeded the Saxon thanes who were *ealdormen*, their own title evidently having been derived from the *jarl* of Scandinavia.

The nature of a modern earldom is readily understood, since it is a rank and dignity of nobility which, while it confers no official power or authority, is inalienable, indivisible, and descends in regular succession to all the male heirs of the body of the grantee until, on their failure, it merges in the Crown. Not so was it with either the nature or the descent of the ancient earldoms of England. In early feudal times titles independent of office did not exist. The earls, or *comites*, of those days, therefore, were actual officers, each having supreme authority in his own earldom, or "county," under the Crown; each one of them also deriving from his earldom a certain fixed revenue, the possession of which was at once an appanage of his official dignity as earl, and the evidence of his lawful and recognized title to it. But an earldom has long ceased to be endowed with any official associations whatever, and has become merely a title by which its owners in male succession inherit and hold the dignity, third in rank, of a peerage. In like manner, the descent and tenure of the ancient earldoms differed in many highly important particulars from the simple succession of the modern dignity. In the course of their chequered history, we find ancient earldoms, instead of passing by a quiet and clearly defined succession from father to son, constantly depending on the rights of female inheritance; they are seen to have been obtained by many a husband *jure uxoris*; they appear to have been transferred in an arbitrary manner, or actually to have been divided between coparceners, or to have been retained for a while by the Crown and let out to farm. At the same

time, under such strange conditions as these, and amidst conflicting vicissitudes, until they finally merged in the Crown, the ancient earldoms retained their vitality. They might descend very irregularly, and become vested in successive families, but still they did not become extinct; nor were the claims of legal inheritance wholly forgotten or superseded; and, even if for a time they had been latent or had actually been superseded, they emerged under more favourable circumstances, and under fresh arrangements or modifications they were again recognized by the Crown.

An earl is "Right Honourable," and is styled "My Lord." His eldest son bears his father's "second title," and therefore, that second title being in most cases a viscountcy, he generally is styled "Viscount;" under all circumstances, however, the eldest son of an earl takes precedence immediately after the viscounts. The younger sons of earls are "Honourable," but all their daughters are "Ladies." In formal documents and instruments, the sovereign, when addressing or making mention of any peer of the degree of an earl, usually designates him "trusty and well-beloved cousin,"—a form of appellation first adopted by Henry IV., who either by descent or alliance was actually related to every earl and duke in the realm. The wife of an earl is a countess; she is "Right Honourable," and is styled "My Lady."

The coronet of an earl has, rising from a golden circlet, eight lofty rays of gold, each of which upon its point supports a large pearl, also, between each pair of rays, at their bases, there is a golden conventional leaf, the stalks of all these leaves being connected with the rays and with each other so as to form a continuous wreath. In representations, five of the elevated rays with their pearls and four of the leaves are shown. The cap and lining of the coronet, if worn or represented, are the same as those of the ducal coronet. An earl's coronet without cap or lining is represented in the annexed figure.

Earl's Coronet.

In the monumental effigies of noble personages, which yet remain from the Middle Ages, there are many highly interesting representations of the varieties of coronets worn by the earls of those days and by their countesses, before this coronet had assumed its present fixed and definite character. Thus, early in the 15th century, effigies of an earl and countess of Arundel, at Arundel, have very rich coronets. The earl's has a series of leaves and of clusters of three small balls or pearls alternating, all of them being raised to a considerable height above the circlet, the clusters rising rather higher than the leaves. The coronet of the countess differs in having the raised clusters set alternately with single balls or pearls that are less elevated.¹

The coronet of a countess now in all respects is the same as that of an earl. The scarlet parliamentary robe of an earl has three doublings of ermine. The duke of Norfolk, who is premier duke, as earl of Arundel, Surrey, and Norfolk, is premier earl of England; also he holds his earldom of Arundel, a feudal dignity (as it was adjudged by

¹ In his effigy at Warwick, 1439, the crest of Richard Beauchamp earl of Warwick, rises from a plain circlet that is surmounted by a series of pearls slightly raised, but without any leaves. Still later in the century, 1483, Isabel Plantagenet, countess of Essex, in her brass at Little Easton in Essex, has a series of leaves, no less than thirteen in number, that rise to a uniform slight elevation above the front of an ample coronet; and about the same time, 1457, the coronets of another earl and countess of Arundel have their circlets heightened with an uninterrupted series of architectural conventional leaves, and once more, at Hever, in Kent, the brass to Sir T. Boleyn, K.G., earl of Wiltshire and Ormonde, represents the maternal grandfather of Queen Elizabeth, with the insignia of the Garter, and wearing a rich coronet, the circlet of which is set with small pearls in contact, not raised, and so numerous that upwards of twenty are displayed.

Parliament, the 11th of Henry VI. 1433), by the fact of his hereditary possession of Arundel Castle only. As hereditary Earl-Marshall, his Grace of Norfolk is the head of the College of Arms (c. b.)

EARLE, JOHN (1601?–1665), bishop of Worcester and afterwards of Salisbury, was born at York about 1601. He completed his education at Oxford, first entering Christ Church, and taking his degree of B.A. in 1619. He afterwards passed to Merton College, and graduated M.A. in 1624. He was appointed in 1631 proctor of the university, and the same year became chaplain to Philip, earl of Pembroke, then chancellor of the university. He was soon after presented by this nobleman to the rectory of Bishopstone, in Wiltshire, and, having been introduced to the king, Charles I., was appointed chaplain and tutor to Prince Charles. In 1642 Earle took his degree of D.D., and in the following year was elected one of the famous Assembly of Divines at Westminster. But his sympathies with the king and with the Church of England were so strong that he declined to sit. Early in 1643 he was chosen chancellor of the cathedral of Salisbury; but of this preferment he was soon after deprived. After Cromwell's great victory at Worcester, Earle went abroad, and was named clerk of the closet and chaplain to Charles II. He spent a year at Antwerp in the house of Izaak Walton's friend Dr Morley, who became afterwards bishop of Winchester. He next joined the duke of York (James II.) at Paris, returning to England at the Restoration. He was at once appointed dean of Westminster, and in 1661 was one of the commissioners for revising the liturgy. At the end of November 1662 he was consecrated bishop of Worcester, and was translated, ten months later, to the see of Salisbury. During the plague of London Bishop Earle attended the king and queen at Oxford, and there he died, November 17, 1665. Earle's chief title to remembrance is his witty and humorous work entitled *Microcosmography, or a Piece of the World discovered, in Essays and Characters*, which throws light on the manners of the time. First printed in 1628, it became very popular, and ran through eight editions in the lifetime of the author. A new edition with notes and appendix, containing much interesting matter, by Philip Bliss, was published in 1811. The style is quaint and epigrammatic, and the reader is frequently reminded of Thomas Fuller by such passages as this. "A university dunner is a gentlemen follower cheaply purchased, for his own money has buy'd him." Several reprints of the book have been issued since the author's death; and in 1671 a French translation by J. Dymock appeared with the title of *Le vice ridiculé*. Earle was employed by Charles II. to make the Latin translation of the *Eikon Basilike*, published in 1649.

"Dr Earle," says Lord Clarendon in his *Life*, "was a man of great piety and devotion, a most eloquent and powerful preacher, and of a conversation so pleasant and delightful, so very innocent, and so very facetious, that no man's company was more desired and loved. No man was more negligent in his dress and habit and mien, no man more wary and cultivated in his behaviour and discourse. He was very dear to the Lord Falkland, with whom he spent as much time as he could make his own."

See especially Bliss's edition of the *Microcosmography*, and Arber's Reprint, London, 1868.

EARLOM, RICHARD (1742–1822), English mezzotint engraver, was born in London in 1742. His natural faculty for art appears to have been first called into exercise by admiration for the lord mayor's state coach, just decorated by Cipriani. He tried to copy the paintings, and was sent to study under Cipriani. He displayed great skill as a draughtsman, and at the same time acquired without assistance the art of engraving in mezzotint. In 1765 he was employed by Alderman Boydell, then one of the most liberal promoters of the fine arts, to make a series of draw-

ings from the pictures at Houghton Hall; and these he afterwards engraved in mezzotint. His most perfect works as engraver are perhaps the fruit and flower pieces after the Dutch artists Van Os and Van Huysum. Amongst his historical and figure subjects are—Agrippina, after West, Love in Bondage, after Guido Reni; the Royal Academy, the Embassy of Hyderbeck to meet Lord Cornwallis, and a Tiger Hunt, the last three after Zoffany; and Lord Heathfield, after Sir Joshua Reynolds. Earlom also executed a series of 200 facsimiles of the drawings and sketches of Claude Lorraine, which was published in 3 vols. folio, under the title of *Liber Veritatis* (1777–1819). Earlom died in London, October 9, 1822.

EAR-RING, an ornament worn pendent from the ear, and generally suspended by means of a ring or hook passing through the pendulous lobe of the ear. The general usage appears to have been to have ear-rings worn in pairs, the two ornaments in all respects resembling each other; in ancient times, or sometimes more recently among Oriental races, a single ear-ring has sometimes been worn. The use of this kind of ornament, which constantly was of great value and sometimes was made of large size, dates from the remotest historical antiquity, the earliest mention of ear-rings occurring in the book of Genesis. It appears probable that the ear-rings of Jacob's family, which he buried with his strange idols at Bethel, were regarded as amulets or talismans, such unquestionably being the estimation in which some ornaments of this class have been held from a very early period, as they still are held in the East. Among all the Oriental races of whom we have any accurate knowledge, the Hebrews and Egyptians excepted, ear-rings always have been in general use by both sexes; while in the West, as well as by the Hebrews and Egyptians, as a general rule they have been considered exclusively female ornaments. By the Greeks and Romans also ear-rings were worn only by women, and the prevalence of this fashion among the races of classic antiquity is illustrated in a singular manner by the ears of the famous statue of the Venus de' Medici being bored, evidently for the reception of pendent jewels. Ear-rings invariably occupy important positions among the various remains of ancient and mediæval goldsmiths' work that from time to time have rewarded the researches of archaeological inquirers. And these early relics, with rare exceptions objects of great beauty and delicacy, never fail to exemplify the artistic styles of their periods, as they were prevalent among the races by whom each individual jewel was produced. Ear-rings of costly materials and elaborate workmanship have been brought to light in considerable numbers in the Troad and in Peloponnesus by Dr Schliemann; jewels of the same class, of exquisite beauty, and of workmanship that is truly wonderful, have been rescued from the sepulchres of ancient Etruria and Greece by Signor Castellani, other ear-rings of gold of characteristic forms have come down to our own times from the ancient Egyptians; we know well what styles of ear-rings were worn by the Romans of the empire and by the early Scandinavians, and recent researches among the burial places of our Anglo-Saxon predecessors in the occupancy of this island have led to the discovery of jewels in considerable numbers, which among their varieties include ear-rings executed in a style that proves the Anglo-Saxons to have made no inconsiderable advance in the arts of civilization. These same ornaments, which never have fallen into disuse, enjoy at the present day a very high degree of favour, like all other modern jewels, however, the ear-rings of our own times as works of arts can claim no historical attributes, because they consist as well of reproductions from all past ages and of every race as of fanciful productions that certainly can be assigned to no style of art whatever.

EARTH, FIGURE OF THE. The determination of the figure of the earth is a problem of the highest importance in astronomy, inasmuch as the diameter of the earth is the unit to which all celestial distances must be referred. Reasoning, doubtless, from the uniform level appearance of the horizon in any situation in which a spectator can be placed—the variations in altitude of the circumpolar stars as one travels towards the north or south, the disappearance of a ship standing out to sea, and perhaps other phenomena—the earliest astronomers universally regarded this earth as a sphere, and they endeavoured to ascertain its dimensions. Aristotle relates that the mathematicians had found the circumference to be 400,000 stadia. But Eratosthenes appears to have been the first who entertained an accurate idea of the principles on which the determination of the figure of the earth really depends, and attempted to reduce them to practice. His results were very inaccurate, but his method is the same as that which is followed at the present day—depending, in fact, on the comparison of a line measured on the earth's surface with the corresponding arc of the heavens. He observed that at Syene in Upper Egypt, on the day of the summer solstice, the sun was exactly vertical, whilst at Alexandria at the same season of the year its zenith distance was $7^{\circ} 12'$, or one-fiftieth of the circumference of a circle. He assumed that these places were on the same meridian; and, reckoning their distance apart as 5000 stadia, he inferred that the circumference of the earth was 250,000 stadia. A similar attempt was made by Posidonius, who adopted a method which differed from that of Eratosthenes only in using a star instead of the sun. He obtained 240,000 stadia for the circumference. But it is impossible to form any correct opinion as to the degree of accuracy attained in these measures, as the length of the stadium is unknown. Ptolemy in his *Geography* assigns the length of the degree as 500 stadia.

The Arabs, who were not inattentive to astronomy, did not overlook the question of the earth's magnitude. The caliph Almamoun, 814 A.D., having fixed on a spot in the plains of Mesopotamia, despatched one company of astronomers northwards and another southwards, measuring the journey by rods, until each found the altitude of the pole to have changed one degree. But the result of this measurement does not appear to have been very satisfactory. From this time the subject seems to have attracted no attention until about 1500, when Fernel, a Frenchman, measured a distance in the direction of the meridian near Paris by counting the number of revolutions of the wheel of his carriage as he travelled. His astronomical observations were made with a triangle used as a quadrant, and his resulting length of a degree was by a happy chance very near the truth.

The next geodesist, Willebrord Snell, took an immense step in the right direction by substituting a chain of triangles for actual linear measurement. The account of this operation was published at Leyden in 1617. He measured his base line on the frozen surface of the meadows near Leyden, and measured the angles of his triangles, which lay between Alkmaar and Bergen-op-Zoom, with a quadrant and semicircles. He took the precaution of comparing his standard with that of the French, so that his result was expressed in toises (the length of the toise is about 6.39 English feet). The work was recomputed and reobserved by Muschenbroek in 1729.

In 1637 an Englishman, Richard Norwood, published his own determination of the figure of the earth in a volume entitled *The Seaman's Practice, containing a Fundamentall Probleme in Navigation experimentally verified, namely, touching the Compasse of the Earth and Sea and the quantity of a Degree in our English Measures*. It appears that he observed on the 11th June 1633 the sun's meridian altitude

in London as $62^{\circ} 1'$, and on June 6, 1635, his meridian altitude in York as $59^{\circ} 33'$. He measured the distance between these places along the public road partly with a chain and partly by pacing. By this means, through compensation of errors, he arrived at 367,176 feet for the degree—a very fair result.

The application of the telescope to circular instruments was the next important step in the science of measurement. Picard was the first who in 1669, with the telescope, using such precautions as the nature of the operation requires, measured an arc of meridian. He measured with wooden rods a base line of 5663 toises, and a second or base of verification of 3902 toises; his triangulation extended from Malvoisine, near Paris, to Soudon, near Amiens. The angles of the triangles were measured with a quadrant furnished with a telescope having cross-wires in its focus. The difference of latitude of the terminal stations was determined by observations made with a sector on a star in Cassiopeia, giving $1^{\circ} 22' 55''$ for the amplitude. The terrestrial measurement gave 78,850 toises, whence he inferred for the length of the degree 57,060 toises.

Hitherto geodetic observations had been confined to the determination of the magnitude of the earth considered as a sphere, but a discovery made by Richer turned the attention of mathematicians to its deviation from a spherical form. This astronomer, having been sent by the Academy of Sciences of Paris to the island of Cayenne, in South America, for the purpose of determining the amount of terrestrial refraction and other astronomical objects, observed that his clock, which had been regulated at Paris to beat seconds, lost about two minutes and a half daily at Cayenne, and that in order to bring it to measure mean solar time it was necessary to shorten the pendulum by more than a line. This fact, which appeared exceedingly curious, and was scarcely credited till it had been confirmed by the subsequent observations of Varin and Deshayes on the coasts of Africa and America, was first explained in the third book of Newton's *Principia*, who showed that it could only be referred to a diminution of gravity arising either from a protuberance of the equatorial parts of the earth and consequent increase of the distance from the centre or from the counteracting effect of the centrifugal force. About the same time, 1673, appeared the work of Huyghens entitled *De Horologio Oscillatorio*, in which for the first time were found correct notions on the subject of centrifugal force. It does not, however, appear that they were applied to the theoretical investigation of the figure of the earth before the publication of Newton's *Principia*. In 1690 Huyghens, following up the subject, published his treatise entitled *De Causa Gravitatis*, which contains an investigation of the figure of the earth on the supposition that the attraction of every particle is towards the centre.

Between 1684 and 1718 J. and D. Cassini, starting from Picard's base, carried a triangulation northwards from Paris to Dunkirk and southwards from Paris to Collioure. They measured a base of 7246 toises near Perpignan, and a somewhat shorter base near Dunkirk, and from the northern portion of the arc, which had an amplitude of $2^{\circ} 12' 9''$, obtained for the length of a degree 56,960 toises, while from the southern portion, of which the amplitude was $6^{\circ} 18' 57''$, they obtained 57,097 toises. The immediate inference from this was that, the degree diminishing with increasing latitude, the earth must be a prolate spheroid. This conclusion was totally opposed to the theoretical investigations of Newton and Huyghens, and created a great sensation among the scientific men of the day. The question was far too important to be allowed to remain unsettled, and accordingly the Academy of Sciences of Paris determined to apply a decisive test by the measurement of arcs at a great distance from each other. For this purpose some of the most distinguished

members of their body undertook the measurement of two meridian arcs—one in the neighbourhood of the equator, the other in a high latitude; and so arose the celebrated expeditions of the French Academicians. In May 1735, MM. Godin, Bouguer, and De la Condamine, under the auspices of Louis XV., proceeded to Peru, where, assisted by two Spanish officers, after ten years of laborious exertion they measured an arc of $3^{\circ} 7'$ intersected by the equator. The second party consisted of Maupertuis, Clairaut, Camus, Le Monnier, and Outhier, who reached the Gulf of Bothnia in July 1736, they were in some respects more fortunate than the first party, inasmuch as they completed the measurement of an arc near the polar circle of $57'$ amplitude and returned to Europe within sixteen months from the date of their departure.

The measurement of Bouguer and De la Condamine was executed with great care, and on account of the locality, as well as the manner in which all the details were conducted, it has always been regarded as a most valuable determination. The southern limit was at a place called Tarqui, the northern at Cotchesqui. A base of 6272 toises was measured in the vicinity of Quito, near the northern extremity of the arc, and a second base of 5260 toises near the southern extremity. The mountainous nature of the country made the work very laborious, in some instances the difference of heights of two neighbouring stations exceeding a mile. The difficulties with which the observers had to contend were increased by the opposition of the more ignorant of the inhabitants, and they were at times in danger of losing their lives. They had also much trouble with their instruments, those with which they were to determine the latitudes proving untrustworthy. But their energy and ingenuity were equal to the occasion, and they succeeded by simultaneous observations of the same star at the two extremities of the arc in obtaining very fair results. The whole length of the arc amounted to 176,945 toises, while the difference of latitudes was $3^{\circ} 7' 3''$. In consequence of a misunderstanding that arose between De la Condamine and Bouguer, their operations were conducted separately, and each wrote a full and interesting account of the operation. Bouguer's book was published in 1749; that of De la Condamine in 1751. The toise used in this measure was ever after regarded as the standard toise, and is always referred to as the *Toise of Peru*.

The party of Maupertuis, though their work was quickly despatched, had also to contend with great difficulties. They were disappointed in not being able to make use of the small islands in the Gulf of Bothnia for the trigonometrical stations, and were forced to penetrate into the forests of Lapland. They commenced operations at Tornea, a city situated on the mainland near the extremity of the gulf. From thence, the southern extremity of their arc, they carried a chain of triangles northward to the mountain Kittis, which they selected as the northern terminus. In the prosecution of this work they suffered greatly from cold and the bites of flies and gnats. The latitudes were determined by observations with a sector (made by Graham) of the zenith distance of α and δ Draconis. The base line was measured on the frozen surface of the river Tornea about the middle of the arc, two parties measured it separately, and they differed by about 4 inches. The result of the whole was that the difference of latitudes of the terminal stations was $57^{\circ} 29' 6''$, and the length of the arc 55,023 toises. In this expedition, as well as in that to Peru, observations were made with a pendulum to determine the force of gravity; and these observations coincided with the geodetical results in proving that the earth was an oblate and not prolate spheroid.

In 1740 was published in the Paris *Mémoires* an account, by Cassini de Thury, of a remeasurement by himself and

Lacaille of the meridian of Paris. With a view to determine more accurately the variation of the degree along the meridian, they divided the distance from Dunkirk to Collioure into four partial arcs of about two degrees each, by observing the latitude at five stations. The anomalous results previously obtained by J. and D. Cassini were not confirmed, but on the contrary the length of the degree derived from these partial arcs showed on the whole an increase with increasing latitude. In continuation of their labours, Cassini and Lacaille further measured an arc of parallel across the mouth of the Rhone. The difference of time of the extremities was determined by the observers at either end noting the instant of a signal given by flashing gunpowder at a point near the middle of the arc.

While at the Cape of Good Hope in 1752, engaged in various astronomical observations, Lacaille measured an arc of meridian of $1^{\circ} 13' 17''$, which gave him for the length of the degree 57,037 toises—an unexpected result, which has led to the modern remeasurement of the arc by Sir Thomas Maclear.

Passing over the measurements made between Rome and Rimini and on the plains of Piedmont by the Jesuits Boscovich and Beccaria, and also the arc measured with deal rods in North America by Messrs. Mason and Dixon, we come to the commencement of the English triangulation. In 1783, in consequence of a representation from Cassini de Thury on the advantages that would accrue to science from the geodetic connection of Paris and Greenwich, General Roy was with the king's approval appointed by the Royal Society to conduct the operations on the part of this country,—Count Cassini, Mechain, and Delambre being appointed on the French side. And now a precision previously unknown was brought into geodesy by the use of Ramsden's splendid theodolite, which was the first to make the spherical excess of triangles measurable. The wooden rods with which the first base was measured were speedily replaced by glass rods, which again were rejected for the steel chain of Ramsden. The details of this operation are fully given in the *Account of the Trigonometrical Survey of England and Wales*. Shortly after this, the National Convention of France, having agreed to remodel their system of weights and measures, chose, as applicable to all countries, for their unit of length the ten-millionth part of the meridian quadrant. In order to obtain this length precisely, the remeasurement of the French meridian was resolved on, and deputed to Delambre and Mechain. The details of this great operation will be found in the *Base du Système Métrique Décimale*. The arc was subsequently extended by MM. Biot and Arago to the island of Iviza.

The appearance in 1838 of Bessel's classical work entitled *Gradmessung in Ostpreussen* marks an era in the science of geodesy. Here we find the method of least squares, a branch of the theory of probabilities, applied to the calculation of a network of triangles and the reduction of the observations generally. This work has been looked on as a model ever since, and probably it will not soon be superseded as such. The systematic manner in which all the observations were taken with the view of securing final results of extreme accuracy is admirable. The triangulation, which is a small one, extends about a degree and a half along the shores of the Baltic in a N.N.E. direction. The compound bars with which he measured his base line may be understood by the following brief description. On the surface of an iron bar two toises in length is laid a zinc bar, both being very perfectly planed and in free contact—the zinc bar being slightly shorter than the iron bar. They are united at one end only, and as the temperature varies the difference of length of the bars as seen at the other end varies, this difference of length is a thermometrical indica-

tion whereby a correction for temperature can be applied to the bars so as to reduce their length to that at the standard temperature. The bars in measuring were not allowed to come into contact, but the intervals left were measured by the interposition of a glass wedge. The results of all the comparisons of the four measuring rods with one another, and with the standards, are elaborately worked out by least squares. The angles were observed with theodolites of 12 and 15 inches diameter, and the latitudes determined by means of the transit instrument in the prime vertical—a method much used in Germany. The formulæ employed in the reduction of the astronomical observations are very elegant. The reduction of the triangulation was carried out in the most thorough manner,—the sum of the squares of all the actual theodolite observations being made a minimum. As it is usual now to follow this method (sometimes only approximately) in all triangulations where great precision is required, we here give a brief description of the method. The equations of condition of a triangulation are those which exist between the supernumerary observed quantities and their calculated values, for, after there are just sufficient observations to fix all the points, then any angle that may be subsequently observed can be compared with its calculated value. If a triangulation consist of $n+2$ points, two of which are the ends of a base line, then to fix the n points $2n$ angles suffice; so that if m be the actual number of angles really observed, the triangulation must afford $m-2n$ equations of condition. To show how these arise, suppose that from a number m of fixed points A, B, C . . . a new point P is observed, which m points are again observed from P, then there will be formed $m-1$ triangles, in each of which the sum of the observed angles is $= 180^\circ +$ the spherical excess; this gives at once $m-1$ equations of condition. The $m-2$ distances will each afford an equation of the form

$$\frac{PC}{PB} \frac{PB}{PA} \frac{PA}{PC} = 1,$$

not, however, limited to three factors. Should P observe the m points and not be observed back, there will be $m-3$ equations of the above form (they are called side equations). In a similar manner other cases can be treated. In practice the ratios of sides are replaced by the ratios of the sines of the corresponding opposite angles. To each observed angle a symbolical correction is applied, so that if α be an observed angle and $\alpha+x$ the true or most probable angle, $\sin(\alpha+x) = \sin \alpha(1+x \cot \alpha)$, x being a small angle whose square is neglected. Thus the side equation takes the form $\beta + \beta_1 x_1 + \beta_2 x_2 + \dots + \beta_n x_n = 0$. In the case of equations formed by adding together the three observed angles of a triangle the co-efficients are of course unity. The problem then is this: Given n equations

$$\begin{aligned} \beta + \beta_1 x_1 + \beta_2 x_2 + \dots + \beta_n x_n &= 0 \\ \beta' + \beta'_1 x_1 + \beta'_2 x_2 + \dots + \beta'_n x_n &= 0 \\ \beta'' + \beta''_1 x_1 + \beta''_2 x_2 + \dots + \beta''_n x_n &= 0 \end{aligned}$$

between $m(m > n)$ unknown quantities $x_1 \dots x_n$, which are the corrections (expressed in seconds of arc) to the observed angles, it is required to determine these quantities so as to render the function $w_1 x_1^2 + w_2 x_2^2 + w_3 x_3^2 + \dots + w_n x_n^2$ a minimum, where $w_1 \dots w_n$ are the weights of the determinations of the angles to which the corresponding corrections belong. The corrections $x_1 \dots x_n$ fulfilling this condition of minimum have, according to the theory of least squares, a higher probability than any other system of corrections that merely satisfy the equations of condition. Multiply the n equations by multipliers $\lambda_1, \lambda_2, \dots, \lambda_n$, and we obtain by the theory of maxima and minima m equations

$$\begin{aligned} w_1 x_1 &= \beta_1 \lambda_1 + \beta'_1 \lambda_2 + \beta''_1 \lambda_3 + \dots \\ w_2 x_2 &= \beta_2 \lambda_1 + \beta'_2 \lambda_2 + \beta''_2 \lambda_3 + \dots \\ &\vdots \\ w_n x_n &= \beta_n \lambda_1 + \beta'_n \lambda_2 + \beta''_n \lambda_3 + \dots \end{aligned}$$

The values of $x_1 \dots x_n$ obtained from these equations are to be substituted in the original equations of condition, and then there will be n equations between the n multipliers $\lambda_1 \dots \lambda_n$. These being solved, the numerical values of $\lambda_1 \dots \lambda_n$ will be obtained, and on substituting these in the last equations written down, the values of $x_1 \dots x_n$ will follow. The process is a long and tedious one; but it is inevitable if we wish very good results.

The great meridian arc in India was commenced by Colonel Lambton at Punnæ in latitude $8^\circ 9'$. Following generally the methods of the English survey, he carried his triangulation as far north as $20^\circ 30'$. The work then passed into the able hands of Sir George (then Captain) Everest, who continued it to the latitude of $29^\circ 30'$. Two admirably written volumes by Sir George Everest, published in 1830 and in 1847, give all the details of the vast undertaking. The great trigonometrical survey of India is now being prosecuted with great scientific skill by Colonel Walker, R.E., and it may be expected that we shall soon have some valuable contributions to the great problem of geodesy. The working out of the Indian chains of triangle by the method of least squares presents peculiar difficulties, but enormous in extent as the work is, it is being thoroughly carried out. The ten base lines on which the survey depends were measured with Colby's compensation bars.

These compensation bars were also used by Sir Thomas Maclear in the measurement of the base line in his extension of Lacaille's arc at the Cape. The account of this operation will be found in a volume entitled *Verification and Extension of Lacaille's Arc of Meridian at the Cape of Good Hope*, by Sir Thomas Maclear, published in 1866. Lacaille's amplitude is verified, but not his terrestrial measurement.

The number of stations in the principal triangulation of Great Britain and Ireland is about 250. At 32 of these the latitudes were determined with Ramsden's and Airy's zenith sectors. The theodolites used for this work were, in addition to the two great theodolites of Ramsden which were used by General Roy and Captain Kater (and which are now in as good condition as when they came from the hands of the maker), a smaller theodolite of 18 inches diameter by the same mechanician, and another of 24 inches diameter by Messrs Troughton and Simms. Observations for determination of absolute azimuth were made with these instruments at a large number of stations; the stars α, δ , and λ Ursæ Minoris and 51 Cephei being those observed, always at the greatest azimuths. At six of these stations the probable error of the result is under $0''\cdot4$, at twelve under $0''\cdot5$, at thirty-four under $0''\cdot7$: so that the absolute azimuth of the whole network is determined with extreme accuracy. Of the seven base lines which have been measured, five were by means of steel chains and two with Colby's compensation bars. This is a system of six compound bars self-correcting for temperature. The compound bar may be thus described. Two bars, one of brass and the other of iron, are laid side by side, parallel, and firmly united at their centres, from which they are free to expand or contract, at the standard temperature they are of the same length. Let AB be one bar, A'B' the other; draw a line through the corresponding extremities A, A' to P, and a line through the other extremities B, B' to Q, make A'P = B'Q, AA' being = BB'. Now if A'P is to AP as the rate of expansion of the bar A'B' to the rate of expansion of the bar AB, then clearly the distance PQ will be invariable, or very nearly so. In

the actual instrument P and Q are finely engraved dots at the distance of 10 feet apart. In the measurement the bars when aligned do not come into contact; an interval of six inches is left between each bar and its neighbour. This small space is measured by an ingenious micrometrical arrangement constructed on exactly the same principle as the bars themselves. The triangulation was computed by least squares. The total number of equations of condition for the triangulation is 920; if therefore the whole had been reduced in one mass, as it should have been, the solution of an equation of 920 unknown quantities would have occurred as a part of the work. To avoid this an approximation was resorted to; the triangulation was divided into twenty-one parts or figures; four of these, not adjacent, were first adjusted by the method explained, and the corrections thus determined in these figures carried into the equations of condition of the adjacent figures. The average number of equations in a figure is 44, the largest equation is one of 77 unknown quantities.¹

Airy's Zenith Sector is too well known to need description. The vertical limb is read by four microscopes, altogether, in the complete observation of a star there are 10 micrometer readings and 12 level readings. In some recent observations in Scotland for latitude the Zenith Telescope has been used with very great success, it is very portable, and a complete determination of latitude, affected with the mean of the declination errors of two stars, is effected by two micrometer readings and four level readings. The observation consists in measuring with the telescope micrometer the difference of zenith distances of two stars which cross the meridian, one to the north and the other to the south of the observer at zenith distances which differ by not much more than 10' or 15', the interval of the times of transit being not less than one nor more than twenty minutes. The advantages are that, with simplicity in the construction of the instrument and facility in the manipulation, refraction is eliminated (or nearly so, as the stars are generally selected within 25° of the zenith), and there is no large divided circle. The telescope, which is counterpoised on one side of the vertical axis, has a small circle for finding, and there is also a small horizontal circle. This instrument is universally used in American geodesy.

The United States Coast Survey has a principal triangulation extending for about 9° 30' along the coast, but the final results are not yet published.

In 1860 was published F. G. Struve's *Arc du Méridien de 25° 20' entre le Danube et la Mer Glaciale mesuré depuis 1816 jusqu'en 1855*. This work is the record of a vast amount of scientific labour and is the greatest contribution yet made to the question of the figure of the earth. The latitudes of the thirteen astronomical stations of this arc were determined partly with vertical circles and partly by means of the transit instrument in the prime vertical. The triangulation, a great part of which, however, is a simple chain of triangles, is reduced by the method of least squares, and the probable errors of the resulting distances of parallels is given; the probable error of the whole arc in length is ± 6.2 toises. Ten base lines were measured. The sum of the lengths of the ten measured bases is 29,863 toises, so that the average length of a base line is 19,100 feet. The azimuths were observed at fourteen stations. In high latitudes the determination of the meridian is a matter of great difficulty; nevertheless the azimuths at all the northern stations were successfully determined,—the probable error of the result at Fuglenæs being $\pm 0''\cdot53$.

Mechanical Theory.

Newton appears to have been the first to apply his own newly-discovered doctrine of gravitation, combined with the so-called centrifugal force, to the question of the figure of the earth. Assuming that an oblate ellipsoid of rotation is a form of equilibrium for a homogeneous fluid rotating with uniform angular velocity, he obtained the ratio of the axes 229 : 230, and the law of variation of gravity on the surface. A few years later Huyghens published an investigation of the figure of the earth, supposing the attraction of every particle to be towards the centre of the earth, obtaining as a result that the proportion of the axes should be 578 : 579. In 1740 Maclaurin wrote his celebrated essay on the tides, one of the most elegant geometrical investigations ever made. He demonstrated that the oblate ellipsoid of revolution is a figure which satisfies the conditions of equilibrium in the case of a revolving homogeneous fluid mass whose particles attract one another according to the law of the inverse square of the distance, he gave the equation connecting the ellipticity with the proportion of the centrifugal force at the equator to gravity, and he determined the attraction on a particle situated anywhere on the surface of such a body. Some few years afterwards Clairaut published (1743) his *Théorie de la Figure de la Terre*, which contains, among other results, demonstrated with singular elegance, a very remarkable theorem which establishes a relation between the ellipticity of the earth and the variations of gravity at different points of its surface. Assuming that the earth is composed of concentric ellipsoidal strata having a common axis of rotation each stratum homogeneous in itself, but the ellipticities and densities of the successive strata varying according to any law, and that the superficial stratum has the same form as if it were fluid, he proves the very important theorem contained in the equation

$$\frac{g-g'}{g} + e = \frac{5}{2}m,$$

Where g, g' are the amounts of gravity at the equator and at the pole respectively, e the ellipticity of the meridian, and m the ratio of the centrifugal force at the equator to g . Clairaut also proved that the increase of gravity in proceeding from the equator to the poles is as the square of the sine of the latitude. This, taken with the former theorem, gives the means of determining the earth's ellipticity from observation of the comparative force of gravity at any two places. Clairaut would seem almost to have exhausted the subject, for although much has been written since by mathematicians of the greatest eminence, yet, practically, very little of importance has been added. Laplace, himself a prince of mathematicians, who had devoted much of his own time to the same subject, remarks on Clairaut's work that "the importance of all his results and the elegance with which they are presented place this work amongst the most beautiful of mathematical productions" (Todhunter's *History of the Mathematical Theories of Attraction and the Figure of the Earth*, vol. i. p. 229).

The problem of the figure of the earth treated as a question of mechanics or hydrostatics is one of great difficulty, and it would be quite impracticable but for the circumstance that the surface differs but little from a sphere. In order to express the forces at any point of the body arising from the attraction of its particles, the form of the surface is required, but this form is the very one which it is the object of the investigation to discover, hence the complexity of the subject, and even with all the present resources of mathematicians only a partial and imperfect solution can be obtained, and that not without some labour. We may, however, here briefly indicate the line of reasoning by which some of the most important of the results were

¹ See the volume of the Ordnance Survey, entitled *Account of the Principal Triangulation of Great Britain and Ireland*, by Captain A. R. Clark, R.E., F.R.S., 1853.

have alluded to above may be obtained. The principles of hydrostatics show us that if X, Y, Z be the components parallel to three rectangular axes of the forces acting on a particle of a fluid mass at the point x, y, z , then, p being the pressure there, and ρ the density,

$$dp = \rho(Xdx + Ydy + Zdz);$$

and for equilibrium the necessary conditions are, that $\rho(Xdx + Ydy + Zdz)$ be a complete differential, and at the free surface $Xdx + Ydy + Zdz = 0$. This equation implies that the resultant of the forces is normal to the surface at every point, and in a homogeneous fluid it is obviously the differential equation of all surfaces of equal pressure. If the fluid be heterogeneous then it is to be remarked that for forces of attraction according to the ordinary law of gravitation, if X, Y, Z be the components of the attraction of a mass whose potential is V , then

$$Xdx + Ydy + Zdz = \frac{dV}{dx}dx + \frac{dV}{dy}dy + \frac{dV}{dz}dz,$$

which is a complete differential. And in the case of a fluid rotating with uniform velocity, in which the so-called centrifugal force enters as a force acting on each particle proportional to its distance from the axis of rotation, the corresponding part of $Xdx + Ydy + Zdz$ is obviously a complete differential. Therefore for the forces with which we are now concerned $Xdx + Ydy + Zdz = dU$, where U is some function of x, y, z , and it is necessary for equilibrium that $dp = \rho dU$ be a complete differential; that is, ρ must be a function of U or a function of p , and so also p a function of U . So that $dU = 0$ is the differential equation of surfaces of equal pressure and density.

We may now show that a homogeneous fluid mass in the form of an oblate ellipsoid of revolution having a uniform velocity of rotation can be in equilibrium. It may be proved that the attraction of the ellipsoid $x^2 + y^2 + z^2(1 + \epsilon^2) = c^2(1 + \epsilon^2)$ upon a particle P of its mass at x, y, z has for components

$$X = Ax, \quad Y = Ay, \quad Z = Cz,$$

where

$$A = 2\pi\rho\left(\frac{1+\epsilon^2}{\epsilon^3} \tan^{-1}\epsilon - \frac{1}{\epsilon^2}\right)$$

$$C = 4\pi\rho\left(\frac{1+\epsilon^2}{\epsilon^2} - \frac{1+\epsilon^2}{\epsilon^3} \tan^{-1}\epsilon\right)$$

Besides the attraction of the mass of the ellipsoid, the centrifugal force at P has for components $-x\omega^2, -y\omega^2, 0$, then the condition of fluid equilibrium is

$$(A - \omega^2)x dx + (A - \omega^2)y dy + Cz dz = 0,$$

which by integrating gives

$$(A - \omega^2)(x^2 + y^2) + Cz^2 = \text{constant}.$$

This is the equation of an ellipsoid of rotation, and therefore the equilibrium is possible. The equation coincides with that of the surface of the fluid mass if we make

$$A - \omega^2 = \frac{C}{1 + \epsilon^2},$$

which gives

$$\frac{\omega^2}{2\pi\rho} = \frac{3 + \epsilon^2}{\epsilon^3} \tan^{-1}\epsilon - \frac{3}{\epsilon^2}.$$

If we would determine the maximum value of ω from this equation, we find that it corresponds to the value of ϵ determined by the condition

$$\tan^{-1}\epsilon = \frac{9\epsilon + 7\epsilon^3}{(1 + \epsilon^2)(9 + \epsilon^2)},$$

hence it may be shown that if the angular velocity exceed that calculated from $\frac{\omega^2}{2\pi\rho} = 0.2247$, equilibrium is impossible for the form of an ellipsoid of revolution. If ω fall short of this limit, there are two ellipsoids which satisfy the condition of equilibrium; in one of these the eccentricity is

greater and in the other less than 0.93. In the case of the earth, which is nearly spherical, we get by expanding the expression for ω^2 in powers of ϵ^2 , rejecting the higher powers, and remarking that the ellipticity $\epsilon = \frac{1}{2}\epsilon^2$,

$$\frac{\omega^2}{2\pi\rho} = \frac{4}{15}\epsilon^2 = \frac{8}{15}\epsilon.$$

Now, if m be the ratio of the centrifugal force at the equator to gravity there,

$$m = \frac{c\omega^2}{\frac{4}{3}\pi\rho c - c\omega^2}, \quad \therefore \frac{\omega^2}{2\pi\rho} = \frac{2}{3} \frac{m}{1+m}.$$

In the case of the earth it is a matter of observation that $m = \frac{1}{289}$, hence the ellipticity

$$\epsilon = \frac{5}{4}m = \frac{1}{231},$$

so that the ratio of the axes on the supposition of a homogeneous fluid earth is 230 : 231, as announced by Newton.

Now, to come to the case of a heterogeneous fluid, we shall assume that its surfaces of equal density are spheroids, concentric and having a common axis of rotation, and that the ellipticity of these surfaces varies from the centre to the outer surface, the density also varying. In other words, the body is composed of homogeneous spheroidal shells of variable density and ellipticity. On this supposition we shall express the attraction of the mass upon a particle in its interior, and then, taking into account the centrifugal force, form the equation expressing the condition of fluid equilibrium. The attraction of the homogeneous spheroid $x^2 + y^2 + z^2(1 + 2e) = c^2(1 + 2e)$, where e is the ellipticity, of which the square is neglected, on an internal particle, whose co-ordinates are $x=f, y=0, z=h$, has for its x and z components

$$X' = \frac{4}{3}\pi\rho f\left(1 - \frac{2}{5}\epsilon\right), \quad Z' = \frac{4}{3}\pi\rho h\left(1 + \frac{4}{5}\epsilon\right),$$

the Y component being of course zero. Hence we infer that the attraction of a shell whose inner surface has an ellipticity ϵ , and its outer surface an ellipticity $\epsilon + d\epsilon$, the density being ρ , is expressed by

$$dX' = -\frac{4}{3} \cdot \frac{2}{5} \pi\rho f d\epsilon, \quad dZ' = \frac{4}{3} \cdot \frac{4}{5} \pi\rho h d\epsilon$$

To apply this to our heterogeneous spheroid, if we put c_1 for the semiaxis of that surface of equal density on which is situated the attracted point P , and c_0 for the semiaxis of the outer surface, the attraction of that portion of the body which is exterior to P , namely, of all the shells which inclose P , has for components

$$X_0 = -\frac{8}{15}\pi f \int_{c_1}^{c_0} \frac{d\epsilon}{d\epsilon} d\epsilon, \quad Z_0 = \frac{16}{15}\pi h \int_{c_1}^{c_0} \rho \frac{d\epsilon}{d\epsilon} d\epsilon,$$

both ϵ and ρ being functions of c . Again the attraction of a homogeneous spheroid of density ρ on an external point f, h has the components

$$X'' = \frac{4}{3}\pi\rho \frac{f}{r^3} \left\{ c^3(1+2e) - \lambda c\epsilon^2 \right\}$$

$$Z'' = \frac{4}{3}\pi\rho \frac{h}{r^3} \left\{ c^3(1+2e) - \lambda'\epsilon^2 \right\}$$

where $\lambda = \frac{3}{5} \cdot \frac{4h^2 - f^2}{r^4}$, $\lambda' = \frac{3}{5} \cdot \frac{2h^2 - 3f^2}{r^4}$, and $r^2 = f^2 + h^2$.

Now ϵ being considered a function of c , we can at once express the attraction of a shell (density ρ) contained between the surface defined by $c + dc$, $\epsilon + d\epsilon$ and that defined by c, ϵ upon an external point, the differentials with respect to c , viz. dX'', dZ'' , must then be integrated with ρ under the integral sign as being a function of c . The integration will extend from $c = 0$ to $c = c_1$. Thus the components of the attraction of the heterogeneous spheroid

upon a particle within its mass, whose co-ordinates are $f, 0, h$, are

$$X = \frac{4}{3} \pi \rho f \left\{ \frac{1}{r^3} \int_0^{c_1} \rho d c^3 (1+2e) - \frac{\lambda}{r^3} \int_0^{c_1} \rho d (c c^3) - \frac{2}{5} \int_{c_1}^{c_0} \rho d c \right\}$$

$$Z = \frac{4}{3} \pi \rho h \left\{ \frac{1}{r^3} \int_0^{c_1} \rho d c^3 (1+2e) - \frac{\lambda'}{r^3} \int_0^{c_1} \rho d (c c^3) + \frac{4}{5} \int_{c_1}^{c_0} \rho d c \right\}$$

We take into account the rotation of the earth by subtracting the centrifugal force $f\omega^2 = F$ from X . Now, the surface of constant density upon which the point $f, 0, h$ is situated gives $(1-2e)f df + h dh = 0$; and the condition of equilibrium is that $(X-F)df + Zd h = 0$. Therefore,

$$(X-F)h = Zf(1-2e),$$

which, neglecting small quantities of the order e^2 and putting $\omega^2 t^2 = 4\pi^2$, gives

$$\frac{2e}{r^3} \int_0^{c_1} \rho d c^3 (1+2e) - \frac{6}{5r^3} \int_0^{c_1} \rho d (c c^3) - \frac{6}{5} \int_{c_1}^{c_0} \rho d c = \frac{3\pi}{t^2}$$

Here we must put now c for c_1 , c for r , and $1+2e$ under the first integral sign may be replaced by unity. Two integrations lead us to the following very important differential equation—

$$\frac{d^2 e}{dc^2} + \frac{2\rho c^2}{f\rho c^2 dc} \cdot \frac{dc}{dc} + \left(\frac{2\rho c}{f\rho c^2 dc} - \frac{6}{c^2} \right) e = 0.$$

When ρ is expressed in terms of c , this equation can be integrated. We infer then that a rotating spheroid of very small ellipticity, composed of fluid homogeneous strata such as we have specified, will be in equilibrium; and when the law of the density is expressed, the law of the corresponding ellipticities will follow. If we put M for the mass of the spheroid, then

$$M = \frac{4\pi}{3} \int_0^c \rho d c^3 (1+2e), \text{ and } m = \frac{c^3}{M} \frac{4\pi^2}{t^2},$$

and putting $c=c_0$ in the equation expressing the condition of equilibrium, we find

$$M(2e-m) = \frac{4}{3} \pi \frac{6}{5c^3} \int_0^c \rho d (c c^3),$$

Making these substitutions in the expressions for the forces at the surface, and putting $r = 1 + e - e \frac{h^2}{c^2}$, we get

$$G \cos \phi = \frac{M}{ac} \left\{ 1 - c - \frac{3}{2} m + \left(\frac{5}{2} m - 2e \right) \frac{h^2}{c^2} \right\} \frac{f}{c}$$

$$G \sin \phi = \frac{M}{ac} \left\{ 1 + c - \frac{3}{2} m + \left(\frac{5}{2} m - 2e \right) \frac{h^2}{c^2} \right\} \frac{h}{c}.$$

Here G is gravity in the latitude ϕ , and a the radius of the equator. Since $\sec \phi = \frac{c}{f} \left(1 + e + e \frac{h^2}{c^2} \right)$,

$$G = \frac{M}{ac} \left\{ 1 - \frac{3}{2} m + \left(\frac{5}{2} m - c \right) \sin^2 \phi \right\},$$

which expression contains the theorems we have referred to as discovered by Clairaut.

The theory of the figure of the earth as a rotating ellipsoid has proved an attractive subject to many of the greatest mathematicians, Laplace especially, who has devoted a large portion of his *Mécanique Céleste* to it. In English the principal existing works on the subject are Sir George Airy's *Mathematical Tracts*, where the subject is treated in the lucid style so characteristic of its author, but without the use of Laplace's coefficients, Archdeacon Pratt's *Attractions and Figure of the Earth*, and O'Brien's *Mathematical Tracts*; in the last two Laplace's coefficients are used. In the *Cambridge Transactions*, vol. viii., is a valuable essay by Professor Stokes, in which he proves, without making any assumption whatever as to the ellipticity of internal strata, or as to the past or the present fluidity of the earth

that if the external form of the sea—imagined to percolate the land by canals—be a spheroid with small ellipticity, then the law of gravity will be that found above.¹

An important theorem by Jacobi must not be overlooked. He proved that for a homogeneous fluid in rotation a spheroid is not the only form of equilibrium; an ellipsoid rotating round its least axis may with certain proportions of the axes and a certain time of revolution be a form of equilibrium.²

Local Attraction.

In speaking of the figure of the earth, we mean the surface of the sea imagined to percolate the continents by canals. That this surface should turn out, after precise measurements, to be exactly an ellipsoid of revolution is *a priori* improbable. Although it may be highly probable that originally the earth was a fluid mass, yet in the cooling whereby the present crust has resulted, the actual solid surface has been left in form the most irregular. It is clear that these irregularities of the visible surface must be accompanied by irregularities in the mathematical figure of the earth, and when we consider the general surface of our globe, its irregular distribution of mountain masses, continents, with oceans and islands, we are prepared to admit that the earth may not be precisely any surface of revolution. Nevertheless, there must exist some spheroid which agrees very closely with the mathematical figure of the earth, and has the same axis of rotation. We must conceive this figure as exhibiting slight departures from the spheroid, the two surfaces cutting one another in various lines; thus a point of the surface is defined by its latitude, longitude, and its height above the spheroid of reference. Call this height for a moment n ; then of the actual magnitude of this quantity we can generally have no information, it only obtrudes itself on our notice by its variations. In the vicinity of mountains it may change sign in the space of a few miles; n being regarded as a function of the latitude and longitude, if its differential coefficient with respect to the former be zero at a certain point, the normals to the two surfaces then will lie in the prime vertical; if the differential coefficient of n with respect to the longitude be zero, the two normals will lie in the meridian; if both coefficients are zero, the normals will coincide. The comparisons of terrestrial measurements with the corresponding astronomical observations have ever been accompanied with discrepancies. Suppose A and B to be two trigonometrical stations, and that at A there is a disturbing force drawing the vertical through an angle δ , then it is evident that the apparent zenith of A will be really that of some other place A' , whose distance from A is $r\delta$, when r is the earth's radius; and similarly if there be a disturbance at B of the amount δ' , the apparent zenith of B will be really that of some other place B' , whose distance from B is $r\delta'$. Hence we have the discrepancy that, while the geodetical measurements deal with the points A and B , the astronomical observations belong to the points A' , B' . Should δ, δ' be equal and parallel, the displacements AA', BB' will be equal and parallel, and no discrepancy will appear. The non-recognition of this circumstance often led to much perplexity in the early history of geodesy. Suppose that, through the unknown variations of n , the probable error of an observed latitude (that is, the angle between the normal to the mathematical surface of the earth at the given point and that of the corresponding point on the spheroid of reference) be ϵ , then if we compare two arcs of a degree

¹ See also a paper by Professor Stokes, in the *Cambridge and Dublin Mathematical Journal*, vol. iv. 1849.

² See a paper in the *Proceedings of the Royal Society*, No. 123 1870, by I Todhunter, M.A., F.R.S.

each in mean latitudes, and near each other, say about five degrees of latitude apart, the probable error of the resulting value of the ellipticity will be approximately $\pm \frac{1}{200} \epsilon$, ϵ being expressed in seconds, so that if ϵ be so great as 2" the probable error of the resulting ellipticity will be greater than the ellipticity itself. It is not only interesting, but necessary at times, to calculate the attraction of a mountain, and the consequent disturbance of the astronomical zenith, at any point within its influence. The deflection of the plumb-line, caused by a local attraction whose amount is $A\delta$, is measured by the ratio of $A\delta$ to the force of gravity at the station. Expressed in seconds, the deflection Δ is

$$\Delta = 12'' \cdot 417 \cdot \frac{\delta}{\rho} A,$$

where ρ is the mean density of the earth, δ that of the attracting mass,—the linear unit in expressing A being a mile. Suppose, for instance, a table-land whose form is a rectangle of twelve miles by eight miles, having a height of 500 feet and density half that of the earth; let the observer be two miles distant from the middle point of the longer side. The deflection then is 1" 47.2, but at one mile it increases to 2" 20. At sixteen astronomical stations in the English Survey the disturbance of latitude due to the form of the ground has been computed, and the following will give an idea of the results. At six stations the deflection is under 2", at six others it is between 2" and 4", and at four stations it exceeds 4". There is one very exceptional station on the north coast of Banffshire, near the village of Portsoy, at which the deflection amounts to 10", so that if that village were placed on a map in a position to correspond with its astronomical latitude, it would be 1000 feet out of position! There is the sea to the north and an undulating country to the south, which, however, to a spectator at the station does not suggest any great disturbance of gravity. A somewhat rough estimate of the local attraction from external causes gives a maximum limit of 5", therefore we have 5" unaccounted for, or rather which must arise from unequal density in the underlying strata in the surrounding country. In order to throw light on this remarkable phenomenon, the latitudes of a number of stations between Nairn on the west, Fraserburgh on the east, and the Grampians on the south, were observed, and the local deflections determined. It is somewhat singular that the deflections diminish in all directions, not very regularly certainly, and most slowly in a south-west direction, finally disappearing, and leaving the maximum at the original station at Portsoy.

The method employed by Dr Hutton for computing the attraction of masses of ground is so simple and effectual that it can hardly be improved on. Let a horizontal plane pass through the given station, let r, θ be the polar co-ordinates of any point in this plane, and r, θ, z , the co-ordinates of a particle of the attracting mass, and let it be required to find the attraction of a portion of the mass contained between the horizontal planes $z=0, z=h$, the cylindrical surfaces $r=r_1, r=r_2$, and the vertical planes $\theta=\theta_1, \theta=\theta_2$. The component of the attraction at the station or origin along the line $\theta=0$ is

$$\delta \int_{r_1}^{r_2} \int_{\theta_1}^{\theta_2} \int_0^h \frac{r_2 \cos \theta dr d\theta dz}{(r^2 + z^2)^{\frac{3}{2}}} \\ = \delta h (\sin \theta_2 - \sin \theta_1) \log \frac{r_2 + (r_2^2 + h^2)^{\frac{1}{2}}}{r_1 + (r_1^2 + h^2)^{\frac{1}{2}}}.$$

By taking $r_2 - r_1$ sufficiently small, and supposing h also small, as it usually is, compared with $r_1 + r_2$, the attraction is

$$\sim \delta (r_2 - r_1) (\sin \theta_2 - \sin \theta_1) \frac{h}{r},$$

where $r = \frac{1}{2}(r_1 + r_2)$. This form suggests the following pro-

cedure. Draw on the contoured map a series of equidistant circles, concentric with the station, intersected by radial lines so disposed that the sines of their azimuths are in arithmetical progression. Then, having estimated from the map the mean heights of the various compartments, the calculation is obvious.

In mountainous countries, as near the Alps and in the Caucasus, deflections have been observed to the amount of as much as 29". On the other hand, deflections have been observed in flat countries, such as that noted by Professor Schweitzer, who has shown that, at certain stations in the vicinity of Moscow, within a distance of 16 miles the plumb-line varies 16" in such a manner as to indicate a vast deficiency of matter in the underlying strata. But these are exceptional cases.¹ Since the attraction of a mountain mass is expressed as a numerical multiple of $\delta \cdot \rho$, the ratio of the density of the mountain to that of the earth, if we have any independent means of ascertaining the amount of the deflection, we have at once the ratio $\rho \cdot \delta$, and thus we obtain the mean density of the earth, as, for instance, at Schiehallion, and more recently at Arthur's Seat. A compact mass of great density at a small distance under the surface of the earth will produce an elevation of the mathematical surface which is expressed by the formula

$$y = a\mu \left\{ \frac{1}{(1 + k^2 - 2k \cos \theta)^{\frac{1}{2}}} - 1 \right\},$$

where a is the radius of the (spherical) earth, $a(1 - k)$ the distance of the disturbing mass below the surface, μ the ratio of the disturbing mass to the mass of the earth, and $a\theta$ the distance of any point on the surface from that point, say Q , which is vertically over the disturbing mass. The maximum value of y is at Q , where it is

$$y = \gamma \mu \frac{k}{1 - k}.$$

The deflection at the distance $a\theta$ is

$$\Delta = \frac{\mu k \sin \theta}{(1 + k^2 - 2k \cos \theta)^{\frac{3}{2}}},$$

or since θ is small, putting $h + k = 1$,

$$\Delta = \frac{\mu \theta}{(h^2 + \theta^2)^{\frac{3}{2}}}.$$

The maximum deflection takes place at a point whose distance from Q is to the depth of the mass as $1 : \sqrt{2}$, and its amount is

$$\frac{2}{3\sqrt{3}} \frac{\mu}{h^2}.$$

If, for instance, the disturbing mass were a sphere a mile in diameter, the excess of its density above that of the surrounding country being equal to half the density of the earth, and the depth of its centre half a mile, the greatest deflection would be 5", and the greatest value of y only two inches. Thus a large disturbance of gravity may arise from an irregularity in the mathematical surface whose actual magnitude, as regards height at least, is extremely small.

The effect of the disturbing mass μ on the vibrations of a pendulum would be a maximum at Q ; if ν be the number of seconds of time gained per diem by the pendulum at Q , and σ the number of seconds of angle in the maximum deflection, then it may be shown that

$$\frac{\nu}{\sigma} = \frac{\pi\sqrt{3}}{10};$$

¹ In the *Philosophical Transactions* for 1855 and 1859 will be found Archdeacon Pratt's calculations for the attractions of the Himalayas and the mountain region beyond them, and the consequent deflection of the plumb-line at various stations in India; the subject, which presents many anomalies and difficulties, is very fully gone into in his treatise on the figure of the earth. His computed deflections are vastly greater than anything brought to light by observation.

so that the number of seconds of time by which at the maximum the pendulum is accelerated is about half the number of seconds of angle in the maximum deflection.

Principles of Calculation.

Let α, α' be the mutual azimuths of two points P, Q on a spheroid, λ the chord line joining them, μ, μ' the angles made by the chord with the normals at P and Q, ϕ, ϕ' , ω their latitudes and difference of longitude, and $\frac{x^2+y^2}{a^2} + \frac{z^2}{b^2} - 1 = 0$ the equation of the surface, then if the plane ax passes through P the co-ordinates of P and Q will be

$$x = \frac{a}{\Delta} \cos \phi, \quad x' = \frac{a}{\Delta'} \cos \phi' \cos \omega,$$

$$y = 0, \quad y' = \frac{a}{\Delta'} \cos \phi' \sin \omega,$$

$$z = \frac{a}{\Delta} (1 - e^2) \sin \phi, \quad z' = \frac{a}{\Delta'} (1 - e^2) \sin \phi',$$

where $\Delta = (1 - e^2 \sin^2 \phi)^{\frac{1}{2}}$, $\Delta' = (1 - e^2 \sin^2 \phi')^{\frac{1}{2}}$, and e is the eccentricity. Let f, g, h be the direction cosines of the normal to that plane which contains the normal at P and the point Q, and whose inclinations to the meridian plane of P is α , let also l, m, n and l', m', n' be the direction cosines of the normal at P, and of the tangent to the surface at P which lies in the plane passing through Q, then since the first line is perpendicular to each of the other two and to the chord k , whose direction cosines are proportional to $x' - x, y' - y, z' - z$, we have these three equations

$$\begin{aligned} f(x' - x) + gy' + lz' - z &= 0 \\ fl + gm + hn &= 0 \\ fl' + gm' + hn' &= 0. \end{aligned}$$

Eliminate f, g, h from these equations, and substitute

$$\begin{aligned} l &= \cos \phi & l' &= -\sin \phi \cos \alpha \\ m &= 0 & m' &= \sin \alpha \\ n &= \sin \phi & n' &= \cos \phi \cos \alpha, \end{aligned}$$

and we get

$$(x' - x) \sin \phi + y' \cot \alpha - (z' - z) \cos \phi = 0.$$

The substitution of the values of x, z, x', y', z' in this equation will give immediately the value of $\cot \alpha$, and if we put ζ, ζ' for the corresponding azimuths on a sphere, or on the supposition $e=0$, the following relations exist

$$\cot \alpha - \cot \zeta = e^2 \frac{\cos \phi \cdot Q}{\cos \phi' \cdot \Delta}$$

$$\cot \alpha' - \cot \zeta' = -e^2 \frac{\cos \phi' \cdot Q}{\cos \phi \cdot \Delta'}$$

$$\Delta' \sin \phi - \Delta \sin \phi' = \sin \omega \cdot Q.$$

If from Q we let fall a perpendicular on the meridian plane of P, and from P let fall a perpendicular on the meridian plane of Q, then the following equations become geometrically evident.

$$\lambda \sin \mu \sin \alpha = \frac{a}{\Delta} \cos \phi' \sin \omega$$

$$\lambda \sin \mu' \sin \alpha' = \frac{a}{\Delta'} \cos \phi \sin \omega.$$

Now in any surface $u=0$ we have

$$\begin{aligned} \lambda^2 &= (x' - x)^2 + (y' - y)^2 + (z' - z)^2 \\ -\cos \mu &= \frac{(x' - x) \frac{du}{dx} + (y' - y) \frac{du}{dy} + (z' - z) \frac{du}{dz}}{\lambda \left(\frac{du^2}{dx^2} + \frac{du^2}{dy^2} + \frac{du^2}{dz^2} \right)^{\frac{1}{2}}} \\ \cos \mu' &= \frac{(x' - x) \frac{du}{dx} + (y' - y) \frac{du}{dy} + (z' - z) \frac{du}{dz}}{\lambda \left(\frac{du^2}{dx^2} + \frac{du^2}{dy^2} + \frac{du^2}{dz^2} \right)^{\frac{1}{2}}} \end{aligned}$$

in the present case, if we put

$$1 - \frac{ax'}{a^2} - \frac{z'}{b^2} = U,$$

then

$$\frac{\lambda^2}{a^2} = 2U - e^2 \left(\frac{z' - z}{b} \right)^2$$

$$\cos \mu = \frac{a}{k} \Delta U, \quad \cos \mu' = \frac{a}{k} \Delta' U.$$

Let u be such an angle that

$$\begin{aligned} (1 - e^2)^{\frac{1}{2}} \sin \phi &= \Delta \sin u \\ \cos \phi &= \Delta \cos u, \end{aligned}$$

then on expressing x, x', z, z' in terms of u and u' ,

$$U = 1 - \cos u \cos u' \cos \omega - \sin u \sin u';$$

also, if v be the third side of a spherical triangle, of which two sides are $\frac{1}{2}\pi - u$ and $\frac{1}{2}\pi - u'$ and the included angle ω , using a subsidiary angle ψ such that

$$\sin \psi \sin \frac{v}{2} = e \sin \frac{u' - u}{2} \cos \frac{u' + u}{2},$$

we obtain finally the following equations—

$$k = 2a \cos \psi \sin \frac{v}{2}$$

$$\cos \mu = \Delta \sec \psi \sin \frac{v}{2}$$

$$\cos \mu' = \Delta' \sec \psi \sin \frac{v}{2}$$

$$\sin \mu \sin \alpha = \frac{a}{k} \cos u' \sin \omega$$

$$\sin \mu' \sin \alpha' = \frac{a}{k} \cos u \sin \omega.$$

These determine rigorously the distance, and the mutual zenith distances and azimuths, of any two points on a spheroid whose latitudes and difference of longitude are given.

By a series of reductions from the equations containing ζ, ζ' it may be shown that

$$\alpha + \alpha' = \zeta + \zeta' + \frac{e^4}{4} \omega (\phi' - \phi)^2 \cos^4 \phi_0 \sin \phi_0 + \dots,$$

where ϕ_0 is the mean of ϕ and ϕ' , and the higher powers of e are neglected. A short computation will show that the small quantity on the right-hand side of this equation can never amount even to the ten thousandth part of a second, which is, practically speaking, zero, consequently the sum of the azimuths $\alpha + \alpha'$ on the spheroid is equal to the sum of the spherical azimuths, whence follows this very important theorem (known as Dalby's theorem). If ϕ, ϕ' be the latitudes of two points on the surface of a spheroid, ω their difference of longitude, α, α' their reciprocal azimuths,

$$\tan \frac{\omega}{2} = \frac{\cos \frac{\phi' - \phi}{2}}{\sin \frac{\phi' + \phi}{2}} \cot \frac{\alpha + \alpha'}{2}.$$

The vertical plane at P passing through Q and the vertical plane at Q passing through P cut the surface of the spheroid in two distinct curves. The greatest distance apart of these curves is, if α_0 = the mean azimuth of PQ,

$$\frac{e^2 s^2}{16 a^2} \cos^2 \phi_0 \sin 2\alpha_0$$

This is a very small quantity; for even in the case of a line of 100 miles in length having a mean azimuth $\alpha = 45^\circ$ in the latitude of Great Britain, it will only amount to half an inch, whilst for a line of fifty miles it cannot exceed the sixteenth part of an inch. The geodesic line joining P and Q lies wholly between these two curves.¹ If we designate by P', Q' the two curves (the former being that in the vertical plane through P), then, neglecting quantities of the order $e^2 \theta^2$, where θ is the angular distance of P and Q at the centre of the earth, the geodesic curve makes with P' at P an angle equal to the angle it makes with Q' at Q, each of these angles being a third of the angle of intersection of P' and Q'. The difference of length of the geodesic line and either of the curves P', Q' is, s being the length of either,

$$\frac{s}{360} e^4 \theta^2 \cos^4 \phi_0 \sin^2 2\alpha_0$$

At least this is an approximate expression. Supposing the angle PQ to be as much as 10° , this quantity would be less than one hundredth of an inch.

An idea of the course of a geodesic line may be gathered from the following example. Let the line be that joining Cadiz and St Petersburg, whose approximate positions are

	Cadiz	St Petersburg
Lat.	$36^\circ 22' N$	$59^\circ 56' N$.
Long	$6^\circ 18' W$	$30^\circ 17' E$.

If G be the point on the geodesic corresponding to F on that one of the plane curves which contains the normal at Cadiz (by "corresponding" we mean that F and G are on a meridian) then G is to the north of F, at a quarter of the whole distance from Cadiz GF is 458 feet, at half the dis-

¹ See a paper "On the course of Geodesic Lines on the Earth's Surface" in the *Philosophical Magazine* for 1870.

tance it is 637 feet, and at three quarters it is 473 feet. The azimuth of the geodesic at Cadiz differs 20" from that of the vertical plane, which is the astronomical azimuth. The azimuth of a geodesic line cannot be observed, so that the line does not enter of necessity into practical geodesy, although many formulæ connected with its use are of great simplicity and elegance. The geodesic line has always held a more important place in the science of geodesy among the mathematicians of France, Germany, and Russia than has been assigned to it in the operations of the English and Indian triangulations. Although the observed angles of a triangulation are not geodesic angles, yet in the calculation of the distance and reciprocal bearings of two points which are far apart, and are connected by a long chain of triangles, we may fall upon the geodesic line in this manner—

If A, Z be the points, then to start the calculation from A, we obtain by some preliminary calculation the approximate azimuth of Z, or the angle made by the direction of Z with the side AB or AC of the first triangle. Let P_1 be the point where this line intersects BC; then, to find P_2 , where the line cuts the next triangle side CD, we make the angle BP_1P_2 such that $BP_1P_2 + BP_1A = 180^\circ$. This fixes P_2 , and P_2 is fixed by a repetition of the same process, so for P_3, P_4, P_5, \dots . Now it is clear that the points P_1, P_2, P_3 so computed are those which would be actually fixed by an observer with a theodolite, proceeding in the following manner. Having set the instrument up at A, and turned the telescope in the direction of the computed bearing, an assistant places a mark P_1 on the line BC, adjusting it till bisected by the cross-hairs of the telescope at A. The theodolite is then placed over P_1 , and the telescope turned to A; the horizontal circle is then moved through 180° . The assistant then places a mark P_2 on the line CD, so as to be bisected by the telescope, which is then moved to P_2 , and in the same manner P_3 is fixed. Now it is clear that the series of points P_1, P_2, P_3 approaches to the geodesic line, for the plane of any two consecutive elements $P_{n-1}P_n, P_nP_{n+1}$ contains the normal at P_n .

From the formulæ which we have given above, expressing the mutual relations of two points P, Q on a spheroid, we may obtain the following solution of the problem: Given the latitude ϕ of P, with the azimuth α and distance s of Q, to determine the latitude and longitude of Q and the back azimuth α' .

$$\begin{aligned} \text{Let } \theta &= \frac{s}{a} \Delta \\ \zeta &= \frac{c^2 \theta^2}{4(1-c^2)} \cos^2 \phi \sin 2\alpha \\ \zeta' &= \frac{c^2 \theta^3}{6(1-c^2)} \cos^2 \phi \cos^2 \alpha; \end{aligned}$$

ζ, ζ' are always very minute quantities even for the longest distances, then, putting $\kappa = 90^\circ - \phi$,

$$\begin{aligned} \tan \frac{\alpha' + \zeta - \alpha}{2} &= \frac{\sin \frac{1}{2}(\kappa - \theta - \zeta')}{\sin \frac{1}{2}(\kappa + \theta + \zeta')} \cot \frac{\alpha}{2} \\ \tan \frac{\alpha' + \zeta + \alpha}{2} &= \frac{\cos \frac{1}{2}(\kappa - \theta - \zeta')}{\cos \frac{1}{2}(\kappa + \theta + \zeta')} \cot \frac{\alpha}{2} \\ \phi - \phi' &= \frac{s}{\rho} \frac{\sin \frac{1}{2}(\alpha' + \zeta - \alpha)}{\sin \frac{1}{2}(\alpha' + \zeta + \alpha)} \left(1 + \frac{\theta^2}{12} \cos^2 \frac{\alpha' - \alpha}{2} \right), \end{aligned}$$

here ρ is the radius of curvature of the meridian for the mean latitude $\frac{1}{2}(\phi + \phi')$. These formulæ are approximate only, but they are sufficiently precise even for very long distances.

Meridian Arcs

The length of the arc of meridian between the latitudes ϕ_1 and ϕ_2 is

$$s = \int_{\phi_1}^{\phi_2} \rho d\phi = a \int_{\phi_1}^{\phi_2} \frac{(1-c^2)d\phi}{(1-c^2 \sin^2 \phi)^{\frac{3}{2}}};$$

instead of using the excentricity, put the ratio of the axes = $1-n, 1+n$, then

$$s = \int_{\phi_1}^{\phi_2} \frac{b(1+n)(1-n^2)}{(1+2n \cos 2\phi + n^2)^{\frac{3}{2}}} d\phi.$$

This, after integration, gives

$$\begin{aligned} \frac{s}{b} &= \left(1+n+\frac{5}{4}n^2+\frac{5}{4}n^3 \right) a_0 - \left(3n+3n^2+\frac{21}{8}n^3 \right) a_1 + \left(\frac{15}{8}n^3+\frac{15}{8}n^3 \right) a_2 \\ &\quad - \left(\frac{35}{24}n^3 \right) a_3, \end{aligned}$$

where

$$\begin{aligned} a_0 &= \phi_2 - \phi_1 \\ a_1 &= \sin(\phi_2 - \phi_1) \cos(\phi_2 + \phi_1) \\ a_2 &= \sin 2(\phi_2 - \phi_1) \cos 2(\phi_2 + \phi_1) \\ a_3 &= \sin 3(\phi_2 - \phi_1) \cos 3(\phi_2 + \phi_1) \end{aligned}$$

The part of s which depends on n^3 is very small; in fact, if we calculate it for the longest arc measured, the Russian arc, it amounts to only an inch and a half, therefore we omit this term, and put for $\frac{s}{b}$ the value

$$\left(1+n+\frac{5}{4}n^2 \right) a_0 - \left(3n+3n^2 \right) a_1 + \left(\frac{15}{8}n^2 \right) a_2$$

Now, if we suppose the observed latitudes to be affected with errors, and that the true latitudes are $\phi_1 + x_1, \phi_2 + x_2$, and if further we suppose that $n_1 + dn$ is the true value of $a-b/a+b$, and that n_1 itself is merely a very approximate numerical value, we get, on making these substitutions and neglecting the influence of the corrections x on the position of the arc in latitude, i.e., on $\phi_1 + \phi_2$,

$$\begin{aligned} \frac{s}{b} &= \left(1+n_1+\frac{5}{4}n_1^2 \right) a_0 - \left(3n_1+3n_1^2 \right) a_1 + \left(\frac{15}{8}n_1^2 \right) a_2 \\ &\quad + \left\{ \left(1+\frac{5}{2}n_1 \right) a_0 - \left(3+6n_1 \right) a_1 + \left(\frac{15}{4}n_1 \right) a_2 \right\} dn \\ &\quad + \left\{ 1+n_1-3n_1 \frac{da_1}{da_0} \right\} da_0, \end{aligned}$$

here $da_0 = x_2 - x_1$, and as b is only known approximately, put $b_1 = b(1+u)$, then we get, after dividing through by the coefficient of da_0 , which is $1+n_1-3n_1 \cos(\phi_2 - \phi_1) \cos(\phi_2 + \phi_1)$, an equation of the form $x_2 = x_1 + h + fu + gv$, where for convenience we put v for dn .

Now in every measured arc there are not only the extreme stations determined in latitude, but also a number of intermediate stations, so that if there be $i+1$ stations there will be i equations

$$\begin{aligned} x_2 &= x_1 + f_1 u + g_1 v + h_1 \\ x_3 &= x_2 + f_2 u + g_2 v + h_2 \\ &\vdots \\ x_i &= x_{i-1} + f_{i-1} u + g_{i-1} v + h_{i-1}. \end{aligned}$$

In combining a number of different arcs of meridian, with the view of determining the figure of the earth, each arc will supply a number of equations in u and v and the corrections to its observed latitudes. Then, according to the method of least squares, those values of u and v are the most probable which render the sum of the squares of all the errors x a minimum. The corrections x which are here applied arise not from errors of observation only. The mere uncertainty of a latitude, as determined with modern instruments, does not exceed a very small fraction of a second as far as errors of observation go, but no accuracy in observing will remove the error that may arise from local attraction. This, as we have seen, may amount to some seconds, so that the corrections x to the observed latitudes are attributable to local attraction. Archdeacon Pratt, in his treatise on the figure of the earth, objects to this mode of applying least squares first used by Bessel; but certainly Bessel was right, and the objection is groundless.

Comparisons of Standards

In determining the figure of the earth from the arcs of meridian measured in different countries, one source of uncertainty was, until the last few years, the want of comparisons between the standards of length in which the arcs were expressed. This has been removed by the very extensive series of comparisons recently made at Southampton (see *Comparisons of Standard of Length of England, France, Belgium, Prussia, Russia, India, and Australia, made at the Ordnance Survey Office, Southampton, 1866*, and a paper in the *Philosophical Transactions* for 1873, by Lieut.-Col A. R. Clarke, C.B., R.E., on the further comparisons of the standards of Austria, Spain, the United States, Cape of Good Hope, and Russia). These direct comparisons, which were carried out with the highest attainable precision, are of very great value. The length of the toise has three independent determinations, viz., through the Russian standard double toise, the Prussian toise, and the Belgium toise,—giving for the length of the toise, expressed in terms of the standard yard of England

through the Russian standard 6 39453216 ft
" " Prussian " 6 39453703 ft
" " Belgian " 6 39453215 ft.

By combining all the different comparisons made in England and on the Continent on these bars, by the method of least squares, the final value of the toise is 6 39453348 ft. (log = 0 8058088656), from which the greatest divergence of the three separate results specified above is only half a millionth of a toise, corresponding to ten feet in the earth's radius. From the known ratio of the toise and the metre, 864000 . 443296, we get for the metre

3 28086933 ft (log = 0 5159889356)

That the close agreement between the determinations of the toise is not due to chance will be seen from the fact that the comparisons of the Prussian toise with the English standard involved 2340 micrometer readings and 520 thermometer readings, extending over twenty-five days, the probable error of the resulting length of the toise being $\pm 0\ 00000015$ yard The probable error of the determination of the Belgian toise is $\pm 0\ 00000027$, that of the Russian double toise $\pm 0\ 00000031$. With regard to the metre, there is an independent determination resulting from the comparison of the platinum metre of the Royal Society,—a large number of observations giving for the length of the metre 3 28087206 feet, which differs from the former result by about one millionth part. But this determination, involving the expansion of the bar for 30° of temperature, and being dependent on some old observations of Arago, cannot be allowed any weight in modifying the result obtained through the toises. The Russian standard, compared at Southampton, was that on which the length of their base lines and therefore their whole arc depends.

Calculation of the Semiaxes

We now bring together the results of the various meridian arcs, omitting many short arcs which have been used in previous determinations, but which on account of their smallness have little influence in the result aimed at.

The data of the French arc from Formentera to Dunkirk are—

Stations	Astronomical Latitudes.			Distance of Parallels. Feet.
Formentera	38	39	53 17	
Mountjouy	41	21	44 96	982671 04
Barcelona	41	22	47 90	988701 92
Carcassonne	48	12	54 30	1657287 93
Pantheon	48	50	47 98	3710827 13
Dunkirk	51	2	8 41	4509790 84

The latitude of Formentera as here given is taken from the observations of M. Biot, recorded and computed in the third volume of his *Traité Élémentaire d'Astronomie physique*

The latitude of the Pantheon, given in the *Base du Système Métrique Décimal* (ii 413), is 48° 50' 48" 86 In the *Annales de l'Observatoire Impérial de Paris*, vol. viii page 317, we find the latitude of south face of the observatory determined as 48° 50' 11" 71 The Pantheon being 35" 38 north of this, we thus get a second determination of its latitude. The mean is that given above

The distance of the parallels of Dunkirk and Greenwich, deduced from the recent extension of the triangulation of England into France, in 1862, is 161407.3 feet, which is 3.9 feet greater than that obtained from Captain Kater's triangulation, and 3.2 feet less than the distance calculated by Delambre from General Roy's triangulation. The following table shows the data of the English arc with the distances in standard feet from Formentera.

Stations	Latitudes.			Feet.
Formentera.				
Greenwich	51	28	38 30	4671108 3
Arbury	52	13	26 59	4943837 6
Clifton	53	27	29 50	5394063.4
Kelhe Law	56	14	53 60	6418221 7
Stirling	57	27	49 12	6857328 3
Saxavord	60	49	37-21	8086820 7

The latitude assigned in this table to Saxavord is not the directly observed latitude, which is 60° 49' 38" 58, for there are here a cluster of three points, whose latitudes are astronomically determined, and if we transfer, by means of the geodesic connection, the latitude of *Gerth of Seav* to Saxavord, we get 60° 49' 36" 59; and if we similarly transfer the latitude of *Balta*, we get 60° 49' 36" 46. The mean of these three is that entered in the above table.

For the Indian arc in long. 77° 40' we have the following data:—

	S	9	31 132	Feet.
Punnac				
Putehapolliam	10	59	42 276	1029174 9
Dodagoontah	12	59	52 165	1756562 0
Namthabad	15	5	53 562	2518376 3
Dnumergida	18	3	15 292	3591788 4
Takalkhera	21	5	51 532	4697329 5
Kalanpur	24	7	11 262	5794695 7
Kahann	29	30	48 322	7755835 9

The data of the Russian arc (long 26° 40') taken from M Struve's work are as below:—

			Feet
Staro Nekrassowka	45	20	2 94
Wodolui	47	1	24 98
Sauprunkowzi	48	45	3 04
Kremenetz	50	5	49 95
Belin	52	2	42 16
Neimesch	54	39	4 16
Jacobstadt	56	30	4 97
Dorpat	58	22	47 56
Hogland	60	5	9 84
Kilpi-maki	62	38	5 25
Tornen	65	49	44 57
Stnor-ovi	68	40	58 40
Fuglences	70	40	11 23

From the arc measured by Sir Thomas Maclear in long. 18° 30', we have

			Feet
North End	29	44	17 66
Heerenlogement Berg	31	58	9 11
Royal Observatory.	33	56	3 20
Zwart Kop	34	13	32 13
Cape Point	34	21	6 26

And, finally, for the Peruvian arc, in long 281° 0',

			Feet.
Tarqui	-3	4	32 068
Cotchesqui	0	2	31 387

Having now stated the data of the problem, we may either seek that ellipsoid which best represents the observations, or we may restrict the figure to one of revolution It will be convenient to commence with the supposition of an ellipsoidal figure, as on so doing we can, by a slight alteration in the equations of minimum, obtain also the required figure of revolution It may be remarked that, whatever the real figure may be, it is certain that if we presuppose it an ellipsoid, the arithmetical process will bring out an ellipsoid, which ellipsoid will agree better with all the observed latitudes than any spheroid would, therefore we do not prove that it is an ellipsoid, to prove this, arcs of longitude would be required There is no doubt such arcs will be shortly forthcoming, but as yet they are not available.

The first thing that occurs to one in considering an ellipsoidal earth is the question, What is a meridian curve? It may be defined in different ways: a point moving on the surface in the direction astronomically determined as "north" might be said to trace a meridian, or we may define it as the locus of those points which have a constant longitude, whose zeniths lie in a great circle of the heavens, having its poles in the equator; we adopt this definition. Let *a*, *b*, *c* be the semiaxes, *c* being the polar semiaxis. The equation of the ellipsoid being

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1,$$

if P be any point on the surface, the direction cosines of the normal at P are proportional to

$$\frac{du}{dx}, \frac{du}{dy}, \frac{du}{dz}, \text{ or } \frac{x}{a^2}, \frac{y}{b^2}, \frac{z}{c^2};$$

and if $\frac{1}{2}\pi - \phi$ be the angle between this normal and the minor axis, so that ϕ is the latitude of P, we have

$$\sin \phi = \frac{\frac{z}{c^2}}{\left(\frac{x^2}{a^4} + \frac{y^2}{b^4} + \frac{z^2}{c^4}\right)^{\frac{1}{2}}}.$$

Hence the equation to a "parallel" in which the latitude ϕ is constant is

$$\frac{x^2}{a^4} + \frac{y^2}{b^4} - \frac{z^2}{c^4} \cot^2 \phi = 0.$$

So that in an ellipsoidal earth the parallel is no longer a plane curve. Let longitude be reckoned from the plane of xz . As there are two species of latitude, astronomical and geocentric, so there are in the ellipsoidal earth two species of longitude, geocentric (called u) and astronomical (called ω). Conceive a line passing through the origin in the plane of the equator and directed to a point whose longitude is $\frac{1}{2}\pi + \omega$. The direction cosines of that line are— $\sin \omega$, $\cos \omega$, and 0. Those points of the surface whose normals are at right angles to this line are in the meridian whose longitude is ω ; the condition of perpendicularity is expressed by

$$\frac{x \sin \omega}{a^2} + \frac{y \cos \omega}{b^2} = 0,$$

and this, in fact, is the equation of the meridian, which is still on the ellipsoidal hypothesis a plane curve. The geocentric and astronomical longitudes are connected by the relation

$$a^2 \tan u = b^2 \tan \omega$$

This meridian curve is an ellipse whose minor semi-axis is c , and of which the semi-axis major is some quantity r intermediate between a and b , such that

$$\frac{1}{r^2} = \frac{\cos^2 u}{a^2} + \frac{\sin^2 u}{b^2}.$$

Take two quantities i, k , such that $a^2(1-i) = b^2(1+i) = k^2$, then $k^2 = r^2(1-i \cos 2u)$, and take n such that

$$n = \frac{r-c}{r+c},$$

and substitute the value of r , neglecting the square of i , this gives

$$n = \frac{k-c}{k+c} + \frac{i}{4} \cos 2u$$

Now we have to determine not only the three semi-axes a, b, c , but the longitude of a . Let u_1 be the longitude of one of the measured meridian arcs, u_0 the longitude of a , then, for that arc,

$$\begin{aligned} n &= \frac{k-c}{k+c} + \frac{i}{4} \cos 2(u_1 - u_0) \\ &= \frac{k-c}{k+c} + p \cos 2u_1 + q \sin 2u_1, \end{aligned}$$

where $4p = i \cos 2u_0$, $4q = i \sin 2u_0$.

The normal at P does not pass through the axis of rotation, so that the observed latitudes on an ellipsoid are not exactly the quantities which should be used in the ordinary method of expressing the length of a meridian arc in terms of the latitudes. But it may be shown that this consideration may be neglected.

The data we have collected form 35 equations between the 40 x -corrections to the observed latitudes, and the four unknown quantities determining the elements of the ellipsoid. Suppose n_1 to be an approximate value of the ratio $k-c$ $k+c$, so that

$$\frac{k-c}{k+c} = n_1 + r,$$

where r is a small correction to n_1 and suppose c_1 to be an approximate value of c so that $c = c_1(1+t)$, then the four unknown quantities are p, q, r, t . The result of making the sum of the squares of the 40 corrections a minimum is

	Fect.	Mètres.
a	20926350	6378294.0
b	20919972	6376350.4
c	20853429	6356068.1

$$\frac{a-c}{c} = \frac{1}{285.97}; \quad \frac{b-c}{c} = \frac{1}{313.38}$$

$$\frac{a-b}{c} = \frac{1}{3269.5}$$

Longitude of $a \dots \dots 15^\circ 34'$ East

The meridian of the greater axis passes, in the Eastern Hemisphere, through Spitzbergen, the Straits of Messina, Lake Chad in North Africa, and along the west coast of South Africa,—nearly corresponding to the meridian which passes over the greatest quantity of land in that hemisphere. In the Western Hemisphere it passes through Behring's Straits and through the centre of the Pacific Ocean. The meridian ($105^\circ 34'$ E.) of the minor axis of the equator passes near North-east Cape on the Arctic Sea, through Tong-king and the Straits of Sunda, and corresponds nearly to the meridian which passes over the greatest amount of land in Asia, and in the Western Hemisphere it passes through Smith Sound, the west of Labrador, Montreal, between Cuba and Hayti, and along the west coast of South America, nearly coinciding with the meridian that passes over the greatest amount of land in that hemisphere.

The length of the meridian quadrant passing through Paris, in the ellipsoidal figure given above, is 10001472.5 metres, showing that the length of the ideal French standard is considerably in error as representing the ten-millionth part of the quadrant. The minimum quadrant, in longitude $105^\circ 34'$, has a length of 10000024.5 metres. The probable error of the longitude of the major axis of the equator given above is of course large, as much perhaps as $\pm 15^\circ$.

It has been objected to this figure of three unequal axes that it does not satisfy, in the proportions of the axes, the conditions brought out in Jacobi's theorem. Admitting this, it has to be noted, on the other hand, that Jacobi's theorem contemplates a homogeneous fluid, and this is certainly far from the actual condition of our globe, indeed the irregular distribution of continents and oceans suggests as possible a sensible divergence from a perfect surface of revolution.

If we limit the figure to being an ellipsoid of revolution, we get rid in our equations of two unknown quantities, and the result may be expressed thus:—

	Fect.	Mètres.
a	20926062	6378206.4
c	20855121	6356503.8
$c:a$	293.98	294.98

As might be expected, the sum of the squares of the 40 latitude corrections, viz., 153.99, is greater in this figure than in that of three axes, where it amounts to 138.30. In the Indian arc the largest corrections are at Dodagoontah, $+3''.87$, and at Kalianpur, $-3''.68$. In the Russian arc the largest corrections are $+3''.76$, at Tornea, and $-3''.31$, at Staro Nekkrowka. Of the whole 40 corrections, 16 are under $1''$, 10 between $1''$ and $2''$, 10 between $2''$ and $3''$, and 4 over $3''$. For the ellipsoidal figure the probable error of an observed latitude is $\pm 1''.42$; for the spheroidal it would be very slightly larger. This quantity may be taken therefore as approximately the probable amount of local deflection.

In 1860, the Russian Government, at the instance of M. Otto Struve, imperial astronomer at St Petersburg, invited the co-operation of the Governments of Prussia, Belgium, France, and England, to the important end of connecting their respective triangulations so as to form a continuous chain under the parallel of 52° from the island of Valentia on the south-west coast of Ireland, in longitude $10^\circ 20' 40''$ W., to Orsk on the river Ural in Russia. This grand undertaking was at once set in action, but up to the present

time there are portions of the work still incomplete. On the part of England the triangulation was, in 1862, carried through France into Belgium; and the difference of longitude of Greenwich and Valentia was determined by the Astronomer Royal by means of electric telegraph signals.

Although in theory the determination of differences of longitude by electric telegraph signals may appear extremely simple, yet practically there are very many sources of error which have to be sought out and eliminated by a proper arrangement of the observations. The system has now been brought to such perfection that the astronomical amplitude of arcs of longitude can be determined with nearly as much accuracy as those of latitude, and in a few years the data of the problem of the figure of the earth will thus receive many additions. As an example of the precision arrived at, the difference of longitude of Greenwich Observatory and Harvard Observatory, U.S.A., has been three times determined with the following results:—

	h	m	s
1866 by Anglo-American Cable.	4	44	31 00
1870 by French Cable to Duxbury.	4	44	30 09
1872 by French Cable to St Pierre.	4	44	30 06

But the different determinations of the velocity of transmission of signals present great anomalies.

Pendulum Observations.

In Clairaut's theorem we have seen that if g' be gravity in the latitude of ϕ , g its value at the equator, then $g' = g(1 + q \sin^2 \phi)$. If the same pendulum be swung in different latitudes then the square of the number of vibrations will be proportional to gravity. Hence, if N be the number of vibrations of an invariable pendulum per diem at the equator, N' the number in latitude ϕ , then $N'^2 = N^2(1 + q \sin^2 \phi)$. Thus q can be obtained by observations on the same pendulum in different latitudes, and since $q = \frac{5}{2}m - e$ and m is known, e will at once follow. The pendulum which makes 86400 oscillations per diem in London is observed to lose 136 vibrations at the equator and gain 79 at Spitzbergen.

The limits of space at our disposal here prevent our going into the subject of pendulum experiments, and it seems unnecessary to repeat the investigations that have already been based upon the older pendulum observations. See Airy's *Figure of the Earth*, Baily's paper in the *Memoirs of the Royal Astronomical Society*, General Sabine's *Account of Experiments to determine the Figure of the Earth by means of the Pendulum vibrating seconds in Different Latitudes*, 1825, and a valuable paper in the *Cambridge Philosophical Transactions*, 1849, by Professor Stokes. The pendulum gives an ellipticity certainly somewhat greater than that resulting from arcs of meridian, viz., $\frac{1}{285}r$. An immense number of pendulum observations are now being made at the astronomical stations of geodesical surveys in Germany, Russia, and India, which, when fully published, will throw light more perhaps upon the local variations of gravity than on the figure of the earth. The observations made at the various stations of the Indian meridian are bring to light a physical fact of the very highest importance and interest, namely, that the density of the strata of the earth's crust under and in the vicinity of the Himalayan Mountains is less than that under the plains to the south, the deficiency increasing as the stations of observation approach the Himalayas, and being a maximum when they are situated on the range itself. This accounts for the non-appearance of the large deflections which the Himalayas, according to Archdeacon Pratt's calculations, ought to produce. The Indian pendulum observations also throw some light on the relative variations of gravity at continental, coast, and island stations, showing that, without a single exception, gravity

at the coast stations is greater than at the corresponding continental stations, and greater at island stations than at coast stations. The ellipticity of the earth has also been deduced from the motion of the moon, the quantity $e - \frac{1}{2}m$ entering as a coefficient in the expression for the moon's latitude. The resulting value of the ellipticity is $\frac{1}{287.7}$ (Airy's *Tracts*, p. 188). A value of the ellipticity may also be derived from the precession of the equinoxes, but as this depends on the assumed law of density in the interior of the earth it is not of much importance.

Elements of the Figure as a Solid of Revolution.

$$a = 20926062 \quad b = 20855121.$$

If ρ be the radius of curvature of the meridian in latitude ϕ , ρ' that perpendicular to the meridian, D the length of a degree of the meridian, D' the length of a degree of longitude, r the radius drawn from the centre of the earth, V the angle of the vertical, then

$$\begin{aligned} \rho &= 20890606.6 & - 106411.5 \cos 2\phi + 225.8 \cos 4\phi \\ \rho' &= 20961607.3 & - 35390.9 \cos 2\phi + 45.2 \cos 4\phi \\ D &= 364609.87 & - 1857.14 \cos 2\phi + 3.94 \cos 4\phi \\ D' &= 365538.48 \cos \phi & - 310.17 \cos 3\phi + 0.39 \cos 5\phi \\ \log \frac{r}{a} &= 9.9992645 & + 0.007374 \cos 2\phi - 0.000019 \cos 4\phi \\ V &= 700''.44 \sin 2\phi - 1''.19 \sin 4\phi. \end{aligned} \quad (\text{A. R. C.})$$

EARTHQUAKE. Although the terrible effects which are often produced by earthquakes have in all ages forced themselves upon the attention of man, it is nevertheless only within the last thirty years that the phenomena have been subjected to exact investigation. A new science has been thus established under the name of *seismology* (*σεισμός*, an earthquake). This branch of knowledge, however, has hitherto attracted but few students, and its development in England has been almost exclusively due to the researches of Mr Robert Mallet. References to his principal works will be given at the end of this article.

Accounts of earthquakes are to be found scattered through the writings of many ancient authors, but they are, for the most part, of little value to the seismologist. There is a natural tendency to exaggeration in describing such phenomena, sometimes indeed to the extent of importing a supernatural element into the description. It is true that attempts were made by some ancient writers on natural philosophy to offer a rational explanation of earthquake phenomena, but the hypotheses which their explanations involved are, as a rule, too fanciful to be worth reproducing at the present day. It is therefore unnecessary to dwell upon the references to seismic phenomena which have come down to us in the writings of such historians and philosophers as Thucydides, Aristotle, and Strabo, Seneca, Livy, and Pliny. Nor is much to be gleaned from the pages of mediæval and later writers on earthquakes, of whom the most notable are Fromond (1527), Maggio (1571), and Travagini (1679). In this country, the earliest work worthy of mention is Dr Robert Hooke's *Discourse on Earthquakes*, written in 1668, and read at a later date before the Royal Society. This discourse, though containing many passages of considerable merit, tended but little to a correct interpretation of the phenomena in question. Equally unsatisfactory were the attempts of Priestley and some other scientific writers of the last century to connect the cause of earthquakes with electrical phenomena. The great earthquake of Lisbon in 1755 led the Rev. John Michell, professor of mineralogy at Cambridge, to turn his attention to the subject; and in 1760 he published in the *Philosophical Transactions* a remarkable essay on the Cause and Phenomena of Earthquakes. Regarding the earth as having a liquid interior covered by a comparatively thin crust, he conceived that waves might be generated in this subterranean liquid, and that such waves by shaking the flexible crust would produce the shocks of an earthquake.

His illustration of the movement of the ground is that of a loose carpet thrown into undulations by being shaken at one corner. Although Michell's hypothesis is still accepted, in a modified form, by some geologists, it should be remembered that many arguments of considerable weight have been urged by modern physicists against the doctrine of a liquid nucleus and a thin crust. Whatever the merits of Michell's theory, he failed to understand the true nature of wave-motion, and the way in which it is transmitted during an earthquake shock. Modern seismologists believe that an earthquake is a vibratory motion propagated through the solid materials of the earth, much in the same way that sound is propagated by vibrations in the atmosphere. It appears that this view was first suggested by Dr Thomas Young in his *Lectures on Natural Philosophy*, published in 1807. The development of this view, especially in its quantitative results, lies at the very base of seismology. In 1846 Mr Mallet communicated to the Royal Irish Academy his first paper "On the Dynamics of Earthquakes;" and in the following year the late Mr Hopkins, of Cambridge, presented to the British Association a valuable report in which earthquake-phenomena are discussed in some detail. Since that date the great advances in this country have been made by Mr Mallet, assisted occasionally by the Rev. Professor Haughton and other mathematicians.

Even at the present day, after all that has been written on the subject, but little is really known as to the origin of earthquakes. Probably several distinct causes should be recognized, for it is hardly to be supposed that all subterranean disturbances, differing as they do so widely in intensity and in duration, should be referable to one common mechanism. Any great concussion, even upon the surface, is competent to produce tremors which may be regarded as diminutive earthquakes; thus the great landslip at the Rossberg in Switzerland in 1806 was accompanied by a local quaking of the ground. Volger and Mohr have suggested that some of the small earthquakes which have been felt in Germany may be referred to the falling-in of the roof of enormous subterranean cavities formed by the long-continued solvent action of water on deposits of rock-salt, limestone, and gypsum. Such causes, however, can have given rise to only very petty shocks; and must be quite subordinate to subterranean disturbances of a more general character. The late Mr Poulett Scrope was led to refer most earthquakes to "the snap and jar occasioned by the sudden and violent rupture of solid rock-masses, and perhaps the instantaneous injection into them of intumescent molten matter from beneath." He believed that the rupture of the rocks was due to expansion of deeply seated masses of mineral matter, consequent upon either increased temperature or diminished temperature. It is argued, however, by Mr Mallet, on mechanical principles, that such fractures could produce only very weak impulses; but he believes that some earthquakes, especially those marked by long continued tremors, may be due to the movement and crushing of rock masses by tangential pressures produced by secular cooling of the earth. Steam has always been a favourite agent with seismologists, since it is clearly competent to produce great effects by its sudden generation or by its sudden condensation. It has been suggested that water, finding its way through fissures in the earth's crust, might reach highly-heated rocks and remain quietly, in the spheroidal condition, until a local reduction of temperature suddenly caused it to flash into steam. After all, the origin of earthquakes is probably to be regarded as part only of a much wider question. Whatever causes are competent to produce volcanic action are, in all likelihood, equally competent to produce the ordinary manifestations of seismic energy. A relation is clearly traceable between

the geographical distribution of volcanoes and the chief earthquake-areas; and although it is not for a moment to be supposed that the volcano and the earthquake stand to each other in the relation of cause and effect, it is nevertheless highly probable that they represent merely different expressions of the same subterranean forces.

Whatever may be the real origin of the earthquake shock, it is convenient to regard its effects as proceeding from a concussion or sudden blow delivered underground at some definite centre. This centre of impulse is called the *seismic focus*. It must be borne in mind, however, that such a centre, so far from being anything like a mathematical point, is in nature a subterranean region, which in many cases is no doubt of very large dimensions, measuring perhaps some miles in diameter.

From the seismic centre waves are propagated in all directions through the solid materials of the earth's crust; and if the focus be situated beneath the sea, the vibrations of the ground will be accompanied by undulations of the water. Those waves which pass through the elastic materials of the earth consist, for the most part, of *longitudinal* vibrations, like those of atmospheric sound-waves, and consequently not like ordinary water-waves. In the sound-wave the air is alternately condensed and rarefied, the molecules advancing and retreating in the line of direction in which the wave is travelling. In a water-wave, on the contrary, the molecules of liquid rise and fall, or rather describe closed curves in planes which are transverse to the direction in which the undulation or wave-form advances. According to Mr Hopkins, both orders of vibration—longitudinal and transversal—coexist in the earthquake-wave, and call for investigation. When, for example, the molecules of an iron bar are disturbed by a blow delivered at one end, both kinds of vibration are generally excited, and hence two waves are sent through the bar,—the longitudinal, however, having a much greater velocity than the transversal wave. But it may be doubted whether the seismologist need concern himself with any but longitudinal vibrations. For, admitting that small transversal vibrations are generated at the seismic focus, it is probable that they would be cut off to a great extent during transmission from stratum to stratum. Indeed, the planes of junction between the several beds in stratified deposits would hinder the transmission of transversal vibrations travelling in a direction normal to the strata. Hence Mr Mallet maintains, that in studying the effects of an earthquake, attention may be restricted, without danger of error, to the longitudinal or normal vibrations, the transversal or tangential vibrations being neglected.

Around the seismic centre, or mean focal point, the molecules of the rock will first be squeezed together by the concussion, and then separated by virtue of the elasticity of the solid medium; the onward motion is then rapidly taken up by the next set of molecules, which in like manner are pushed against each other, and then spring apart. In this way the pulse, or form of the wave, may be propagated to an enormous distance, whilst the excursions of the individual particles are confined within very narrow limits. It is therefore of great importance to distinguish between the transit of the wave and the movement of the material particles. Each molecule may move only through a few inches, but the undulation may travel for hundreds of miles. The distance through which the individual particles oscillate is called the *amplitude* of the wave. After the Neapolitan earthquake of 1857 Mr Mallet found from actual observation at a place called Polla, situated nearly above the seismic centre, that the amplitude of a wave which caused certain fractures in masonry could not have been more than 2½ inches. He is thus led to believe, contrary to the opinion of most geologists, that earthquakes are not great agents of

permanent elevation. That elevation has been frequently observed after an earthquake is a fact beyond question, thus, Captain Fitzroy found, after the South American earthquake of 1835, that a part of the isle of Santa Maria, in the Bay of Concepcion, had been raised upwards of 10 feet, and, although this elevation was followed by a slow subsidence, it is believed that the land was permanently left considerably higher than its level before the occurrence of the catastrophe. Mr Mallet, however, would refer such alteration of level to the action of elevatory forces accompanying the earthquake, but not to the direct transit of the earth-wave.

From the density and the modulus of elasticity of a given rock, it is possible to calculate the velocity with which a vibration would travel through such a medium. But the rate deduced by calculation usually exceeds very greatly that actually observed in an earthquake. To determine the rate of transit through various rocks, Mr Mallet and his son Dr J W Mallet conducted many years ago a series of experiments, at the instance of the British Association. A mile was carefully levelled and measured on sand in Killiney Bay, near Dublin, and by explosion of gunpowder the velocity of transmission through this damp sand was observed. This sand was selected as a medium likely to give a minimum velocity, whilst an assumed maximum velocity was observed by experiments on the granite of Killiney Hill. The velocity in sand was about 825 feet, and in solid granite 1665 feet per second. These figures are much lower than those obtained from theoretical considerations, and it is believed that the difference is due to loss of speed occasioned by the discontinuity of the rock, even the solid granite being always more or less affected by joints. The velocity deduced from these experiments accords tolerably well, however, with that observed during earthquake-shocks. Thus the velocity of shock during the Lisbon earthquake of 1755 is computed to have been about 20 miles per minute, or 1760 feet per second. This velocity of the vibration, or wave of shock, is of course to be carefully distinguished from the velocity of the oscillating particles. The mischief of the shock depends in fact on the rate at which the earth-molecules are moving, and this is vastly inferior to that of the wave. Thus Mr Mallet calculated from his observations in Naples that the shock of the great earthquake of 1857 had a mean velocity at the surface of 788 feet per second, whilst the greatest velocity of the wave-particles was never more than 15 feet per second, and in many places was very much less. Yet this low velocity is quite sufficient to produce effects of the most disastrous kind upon solid objects exposed to the shock.

If the earth were a homogeneous solid, perfectly isotropic—that is to say, possessing equal elasticity in all directions—the waves of alternate compression and expansion would take the form of a series of concentric spherical shells around the seismic focus as a common centre. As a matter of fact, however, the crust of the earth is made up of rocks varying greatly in physical properties, each having its own density and elasticity, whilst the rocks themselves are fissured in all directions. Symmetry of wave-surface is therefore hardly to be expected, for the waves will necessarily have greater velocity in one direction than in another, whilst the transit of the wave may be interrupted by breach of continuity in the transmitting medium. The points at which a wave-shell reaches the surface form a curve which is conveniently called a *coseismal line*. It is obviously the line along which an earthquake shock will be simultaneously felt, and where the waves will emerge at the same angle. Since the wave-shells are not concentric spheres, the coseismal curves cannot be concentric circles.

It may readily be supposed that the greatest effect of an earthquake, at least in shaking a building up and down,

will be felt at that point of the surface which is situated vertically over the centre of impulse. A line joining this point with the earthquake-focus is termed the *seismic vertical*, and the wave travelling to the surface along this vertical has a shorter path than that of a wave emerging at any other point. Just as the seismic focus is, in nature, not a single point, but a considerable space, so the seismic vertical is not a single line, but rather a succession of parallel lines drawn vertically from every point of the focal area to the surface. The mean of these lines may be taken as the seismic vertical. In the neighbourhood of this line the waves emerge at very steep angles, and indeed for a considerable area may be regarded as practically vertical in direction. As the distance from the seismic vertical increases, the angle of emergence becomes less and less; but it is evident that since the focus is seated beneath the surface, the path of an emergent wave can never be perfectly horizontal, unless indeed it be that of a reflected wave.

Almost any object which has been overthrown or projected by an earthquake-shock may afford direct information as to the path of the wave along the surface. For when the vibration is transmitted to such a solid body as an upright column, the particles are pushed together and then pulled apart in the line of wave-transit. It is clear too that half the excursion of each particle is executed in the same direction as that in which the wave is travelling, and half in the opposite direction. Each particle of the object when first disturbed moves with the wave, and its velocity increases from zero to the maximum, this maximum being reached at one quarter of the total vibration; then the velocity diminishes from the maximum to zero, which it attains at the end of half the oscillation. During this first semi-phase, therefore, the vibration has been in the direction in which the wave moves. After the first half oscillation has been executed, movement begins afresh, but this time in the contrary direction, attaining its maximum at the end of the third quarter, and then falling again to zero when the vibration is completed. Hence during the first semi-phase, the motion of the particles is in the same sense or direction as that of the wave, and during the second semi-phase in the opposite direction. But in consequence of the inertia of the body its apparent movement if free, will be in a direction contrary to that of the wave during the first semi-phase. Whatever the direction of overthrow, however, it will always be in the line of wave-transit. Hence the azimuthal direction of the wave is easily found.

Whenever any two wave-paths, not in the same right line, can be thus traced on the surface, the position of the seismic vertical may be immediately determined. For this line must pass through the point of their intersection. If, for example, it is found by observation on bodies displaced by the shock that one wave moved in the direction AB (fig 1), whilst another had a path along CD, it is only necessary to mark on the surface the point O, at which these azimuths meet, and the seismic focus will be vertically beneath such a point. The point indicates, in fact, the centre on the surface from which the waves radiated. Practically it is found that the several wave-paths of an earthquake do not diverge from a single point, for reasons already indicated, but intersections of the paths are crowded together in the neighbourhood of the mean vertical.

Fig 1

It is easy to understand that the greatest amount of mechanical damage is not to be expected immediately above the focus, although this is the point nearest to the origin of impulse. It is true, the shock passing directly upwards along the seismic vertical might destroy the roof or floor of a building, but it would not tend directly to overturn the walls or produce lateral disturbance. In fact, the side-thrust will be greatest in waves which reach the surface at small angles, and are therefore necessarily at great distances from the seismic vertical. But the energy of the wave diminishes as the square of the distance along the normal increases. Hence there must be some definite position upon the surface beyond which advantage of direction is counterbalanced by loss of energy. Indeed it is generally possible after an earthquake to trace a zone of maximum disturbance, where the damage to the shaken country has been greatest. The line indicating this maximum is termed the *meizoseismic curve*, whilst lines along which the overthrow of objects may be regarded as practically the same are known as *isoseismic curves*. After what has been already said, it is hardly necessary to remark that these lines are not true circles, nor indeed are they in all cases regular closed curves.

Fractures and fissures in walls which have been rent by an earthquake, are of great value to the seismologist, since they often indicate the direction in which the waves emerge at the surface. The interpretation of such phenomena, in some cases very complicated, has been ably discussed by Mr Mallet, who applied the results with excellent effect to his observations on the Neapolitan earthquake. If it is possible to find, from such indications, the direction in which any two waves emerged at the surface, the depth of the seismic focus is easily determined. For since the waves radiate from this focus, any two wave-paths when produced backwards will meet at the seismic centre. It has already been shown how easily the vertical is found, and when this is known the determination of the focus is simplified, for as the vertical itself represents one-wave path it is necessary to find only one other. Let O (fig. 2) be the seismic focus, and OA the seismic vertical; if a

Fig. 2.

wave, OB , emerge at the surface B , at an angle θ , it is evident that

$$AO = AB \tan \theta.$$

To find the depth of the focus, it is consequently only necessary to know the angle of emergence of a wave at a given station, and the distance of this station from the seismic vertical. As the stations A and B are comparatively near each other, the earth's sphericity may be neglected, and the surface between the two regarded as practically a horizontal plane.

Where several wave-paths are known, several values of AO will be obtained, and as the seismic centre is not a point, like O , but a cavity of determinate magnitude, the average of these different values must be taken to represent the *mean focal depth*. After the great Neapolitan earthquake of 1857, Mr Mallet, aided by the Royal Society, spent some months in carefully examining the country which had been visited by the shock, and in 1862 he published an elaborate report in which his observations were fully discussed. By determining the wave-paths at twenty-six stations in every azimuth around the seismic vertical, he was enabled to deduce the important fact that the mean focal depth of the earthquake was about 53 geographical miles. Similar principles have since been applied by Dr Oldham to an examination of the results of an earthquake which occurred in Cachar in India, on January 10, 1868, and he has found that the seismic focus there must have had a depth of about 30 miles. This coincides very nearly with the depth which Mr Mallet believes to be the maximum at which any earthquake is likely to originate in our planet.

When the centre of disturbance is seated beneath the sea, as appears to have been the case with that which produced the great earthquake of Lisbon in 1755, a water-wave is generated, but since this has less velocity than the earth-wave, it does not roll in upon the shore until after the shock has been felt on land. The height of the sea-wave depends on the depth of the water. During the Lisbon earthquake the wave at Cadiz was as much as sixty feet in height. It is this great sea-wave which, breaking upon the shore after the earthquake-shock, generally completes the work of devastation. At first the water retires from the land, but in a few moments the gigantic wave rolls in, and sweeps all before it. The earthquakes which are so frequently felt on the western coast of South America are generally terminated in this manner, and the great tidal wave which accompanied the earthquake of May 1877, wrought dreadful havoc at Arica, Iquique, and other towns on the coast.

In addition to the waves propagated through earth and sea, it commonly happens that waves are transmitted through the air and thus produce sound. These sound-waves, travelling at the rate of about 1100 feet per second, may reach the observer either simultaneously with the shock or before it or even after it. They probably result from sudden fracture and dislocation of rock-masses, or from subterranean explosions.

Almost every object disturbed by an earthquake may be made to yield, when properly questioned, more or less

information with respect to the direction and intensity of shock. Special instruments termed *seismometers* have, however, been constructed for this purpose, and have assumed considerable variety of form. Perhaps the simplest seismometer is that suggested by Mr Babbage, consisting merely of a bowl of some viscid liquid like treacle. On the passage of a shock the liquid rises up one side of the vessel, leaving its mark to indicate rudely the direction and extent of motion. As a modification of this simple instrument Mr Mallet proposed the use of a common wooden tub having its inside rubbed with chalk, and half filled with coloured water. An apparatus devised by Professor Cacciatore, of Palermo, and much used in Italy, is constructed with a shallow dish having eight notches in the side, and containing mercury up to the level of the lips. When any oscillation occurs, the liquid is spilt into a series of cups placed under the notches, and the quantity ejected, which may be readily weighed, gives some notion of the intensity of the shock. Since the notches face the four cardinal points and bisecting rhumbs, the direction in azimuth is approximately obtained. Mr Mallet suggested a convenient form of seismometer in the shape of a system of four L-shaped glass tubes having the upper ends closed and the horizontal limbs directed to the cardinal points. The tubes are partially filled with mercury, and the horizontal component of any shock causes the mercury to move in the lower limbs; whilst the vertical component is determined by the motion of quicksilver in a U-shaped tube. In both cases, the movement of the liquid column is registered by means of indexes.

All these instruments depend for their indications on the displacement of liquids by the shock of the earthquake. But it is obvious that the oscillations of solid bodies may be equally well employed in seismometry. Thus a pendulum free to move in all directions will be set vibrating by a shock, and may be made to record the direction and extent of its vibration by means of a stile below the bob, which moves over a bed of fine sand in a properly-shaped dish. Two pendulums are sometimes used, as proposed by Santi. One pendulum vibrates in a vertical plane directed north and south, and the other in one striking east and west,—the arcs traversed in these planes being registered by means of a tracing-stile affixed to the bob. Professor J. Forbes employed an inverted pendulum, or rod fixed at its base and weighted above, carrying at its free end a pencil or tracer by which any oscillation could be recorded. A modification of the inverted pendulum was proposed by Mr Budge of Valparaiso, in which the pendulum when moved by the first shock was kept in position at the end of a semi-oscillation, by means of a pawl working in a ratchet on the base of the vibrating body.

Such seismometers as those previously noticed require to have their indications observed after each shock. Several ingenious instruments have, however, been constructed on self-registering principles, so that however often they are disturbed, each movement leaves a permanent record. The first of these self-registering seismometers was devised by Mr Mallet, and described in 1846. Both the horizontal and the vertical element of a shock are recorded by the movement of mercury in a system of glass tubes, the tubes being placed in a galvanic circuit so arranged that contact is broken by displacement of the liquid. As long as the circuit remains complete, a pencil traces a line on ruled paper wound round a cylinder rotated by clock-work, but the motion of the mercury intercepts the current and thus breaks the line. Two forms of "ball seismometer" are also due to the ingenuity of the same investigator. In one of these instruments, two heavy metal balls are placed on slightly inclined planes supported by a cast-iron table, the axis of which passes through a vertical

spiral spring During the passage of an earthquake wave the spring is compressed and the balls displaced,—their displacement breaking contact in an electric circuit which had previously been completed through the balls. That ball which first moves gives the time at which the shock commences, whilst the other gives the elements of the shock. Two such instruments are necessary to form one seismometer, the two being placed at right angles to each other.

An elaborate electro-magnetic seismograph has been constructed by Professor Palmieri, and has done good service in the observatory on Mount Vesuvius. The vertical movements are recorded by a helix of copper wire, the lower end of which is caused by even the slightest shock to dip into a basin of mercury, and thus complete a galvanic circuit. An electro-magnet, brought into action when the connections are completed, strikes an alarm bell which calls an attendant, and also stops a clock, so that the instant at which the shock occurs is permanently marked. At the same time a second electro-magnet releases the pendulum of another clock, which being thus set in motion unrolls a band of paper, while a pencil continues to mark upon the paper as long as the shock lasts. To record the vertical element a system of four U-shaped tubes is employed, the tubes being placed in different azimuths. Each limb is partly filled with mercury, and any oscillation in the level of the liquid is indicated by movement of a little float connected with an index. The oscillation of the quicksilver also completes a galvanic circuit, and brings into action the electro-magnets already described.

Although the limits of this article forbid reference to some other seismometers, such as that of Kreil of Vienna, mention should certainly be made of one instrument which is marked by its extreme simplicity. Its construction, which is due to Mr Mallet, will be understood by reference to fig. 3. Two sets of right cylinders are turned in some

Fig 3

hard material, such as boxwood. The cylinders are all of the same height, but vary in diameter. Two planks of wood are fixed to a level floor, one having its length in a north-and-south, and the other in an east-and-west direction. The cylinders stand upright on the planks in the order of their size, with a space between each pair greater than their height, so that when one pillar falls it does not strike its neighbour. The surrounding floor is covered up to the level of the planks with dry sand. When a shock passes, some of the cylinders are overturned, the number depending on the velocity of the wave. Suppose the shock knocks over the narrow-based cylinders 4, 5, 6, leaving Nos 1, 2, 3 standing; then the velocity of the horizontal component must have been greater than that needed to overturn No. 4, but not great enough to overturn No. 3. Hence the velocity (V) can be approximately obtained by using a formula due to Professor Haughton, viz

$$V^2 = \frac{15b^2 + 16a^2}{12a^2} \cdot g \sqrt{a^2 + b^2} (1 - \cos \theta);$$

where a is the altitude of the column, b the diameter of its base, and θ the angle formed by the side and a line drawn through the centre of gravity to the extremity of the base. The direction in azimuth is indicated by the position in which the overturned pillars are found, since the bed of sand prevents rolling. It is possible to obtain the exact time at which the shock commences by connecting the narrowest-based pillar with the pendulum of a clock so as to stop it at the instant of overthrow. Where the angle of wave-emergence is very steep, this instrument is not to be recommended, since it ignores the vertical element of the shock.

Catalogues of earthquakes, showing their distribution in time and space, have been constructed by Mallet, Perrey, Von Hoff, Cotte, and other seismologists. The most complete of these statistical works is the *catalogue raisonné* compiled by Mr R Mallet and his son, Dr J W Mallet, and published by the British Association between the years 1854 and 1858. This includes notices of all recorded earthquakes from 1606 B C to 1842 A D, and is thence carried on to 1850 from Perrey's annual catalogues. Between 6000 and 7000 separate earthquakes are recorded as having occurred in almost every part of the world, both on land and at sea. But though seismic energy may thus become sensible at any point of the earth's surface, there are, as everyone knows, certain regions peculiarly subject to earthquakes, and it is, in fact, possible to trace seismic bands of variable width following the great lines of elevation which divide the oceanic basins.

It is now several years since Professor Alexis Perrey, of Dijon, sought to trace a relation between the occurrence of earthquakes and the age of the moon. By careful analysis of his catalogue he believed that he had established the facts—that earthquakes occur more frequently at the syzygies than at the quadratures, that their frequency increases at the perigee and diminishes at the apogee of the moon, and that shocks are more frequent when the moon is on the meridian than when 90° from it. Such a connection between seismic phenomena and the phases of the moon would accord with Zantedeschi's views on the existence of a terrestrial or terrene tide, views which were based, however, on the old hypothesis of a liquid nucleus in the earth, covered by a thin crust.

From Mallet's discussion of his catalogue for three centuries, he was led to detect definite periods of maximum energy. Thus it is found that the greatest number of earthquakes are recorded about the middle of each century, whilst a second epoch, less powerful than the first, occurs towards the close of the century. According to Perrey there is a preponderance of earthquake-shocks at particular seasons, the equinoxes and solstices, which he terms "critical epochs." Mallet's analysis of a large catalogue showed a decided maximum about the winter solstice, but Perrey's other epochs were less marked. In the present state of our knowledge it would be rash to regard seismic force, whatever it may be, as a distinctly periodic force, or to insist upon any of those relations between earthquakes and meteorological phenomena which have sometimes been discussed.

Annual reports on earthquakes have been published for many years by Professor Fuchs. During the year 1876 he recorded 104 earthquakes, which were distributed among the months as follows — In January 10, February 10, March 14, April 8, May 7, June 7, July 8, August 5, September 7, October 14, November 5, December 9. In the preceding year 97 earthquakes were noticed, occurring as follows — In January 15, February 7, March 12, April 7, May 9, June 10, July 6, August 5, September 3, October 2, November 9, December 12.

EARWIG, a name, sanctioned by common error, applied under various modifications in different languages (*e.g.*, Auricularia, Perce-oreille, Ohr-wurm, Oorblander, Ormask, Oerentvist, Gusano del oido, &c) to the somewhat osculant insects comprised in the old Linnean genus *Forficula*,—an

error arising in the first instance probably from their invariable habit of secreting themselves in any cavity, of which they always endeavour to reach the innermost recess (instances being known of the common species hiding itself in the ear of a person sleeping in the open air), and strengthened by the popular exaggerated idea of the strength and attributes of the anal forceps peculiar to these insects.

Earwigs have been for some time of uncertain position in classification, having been even considered as worthy of the rank of a special separate order (*Labidoures*, Duméril, *Dermaptera*, corrected to *Dermatoptera*, Leach, and *Euplectoptera*, corrected to *Euplectoptera*, Westwood), but they are now generally recognized as forming a family, *Forficulidae* or *Forficulariæ*, of the *Orthoptera* (the Locusts, Grasshoppers, Crickets, Cockroaches, Mantids, &c.) They have much the faces of the *Brachelytra* or *Staphylinidae* in the *Coleoptera* (Beetles), from which order they differ in their pupa being active, resembling the perfect insect except in possessing only rudimentary wings, &c.; also in the method of folding and neurulation of the hinder wings, the possession of an anal forceps, and, as in the other *Orthoptera*, in the additional external lobe to their maxillæ. From all the other *Orthoptera*, apart from the anal forceps, they differ in having horizontal elytra covering the wings in repose as in beetles, and in the female not possessing a corneous ovipositor, and from most of them in the hind legs being not formed for jumping.

Of distinct species 250 are recognized, comprised in 34 genera (of which some are apparently needless), but it is highly probable that this represents a mere outline of the group, as scarcely any naturalists make them an object of study, and their geographical distribution is very extended. There are about 200 species in the collection of the British Museum alone, mostly unnamed, and not specially collected. They are found in the whole of Europe, in Syria and Asia Minor, Central Asia, Hindustan, Ceylon, Indo-China, China and Formosa, the Malay Archipelago, the Philippines, North, West, and South Africa to the Cape itself, Egypt, Zanzibar, Mauritius, Kamtschatka, Newfoundland, the North American States from New York to California (but comparatively rare, according to Packard), Mexico, Florida, Central America and the West Indies, South America from Columbia to Chili, New Guinea, North Australia, Tasmania, and New Zealand, and species occur in such isolated localities as Madeira, the Canaries, St Helena, Woodlark Island, the Solomon and Sandwich Isles, and Kerguelen's Island. As regards pre-historic times, a few fossil species have been found in the territories of Soleuhausen, Emmingen, and Italy in the Old World, and of the Rocky Mountains (Colorado) in the New. Seven species have been recorded from Great Britain, of which two are universally common, viz., *Forficula auricularia*, the typical earwig, and the smaller *Labia minor*. The former of these is found all over Europe, in Armenia, the Caucasus, and other parts of Asia, and in the eastern United States, being also recorded from Japan, and the latter occurs in Europe, Western Asia, and North America. Another species, *Labidura riparia*, extends over the entire Old World.

All are of comparatively small size, and nearly all of obscure colours, mostly various shades of brown or dull yellows and reds: one South American species is white, another, from the Amazou, has blue metallic elytra, which are metallic also in another from Penang, a fourth exotic species is yellow, with black stripe, and several have opaline or iridescent wings. Eccentricity of development is shown chiefly in the forceps, which in a Nicaraguan species are as long as the rest of the body, in another South American form the abdomen is laterally toothed; a third has very long legs, being almost tipuliform; *Apachys* has the body as thin as cardboard.

Sexual differences are shown in the male by the greater development and armature of the forceps, or the tuberculated abdomen, which is composed of nine distinct segments, whereas only seven are evident in the female. The forceps have been observed to be used in arranging the wings, and are also supposed to be used as weapons of offence and defence, though it is difficult to understand how they could be of any practical assistance for either purpose. The lower wings have long attracted attention from their unexpectedly large size and fan-like structure; in the accompanying figure, *a* is the magnified open wing of the common earwig, *b* the same of the natural size, and *c* the wing closed, also of natural size. Although possessed of such ample organs of flight, *Forficula*

auricularia has seldom, if ever, been observed to make use of them, though there is evidence that it does fly, but the other common British species, *Labia minor*, is frequently seen on the wing, being often mistaken for a brachelytrous beetle. It may be observed, that the possession of wings is apparently sexual in some cases, and that some species are entirely apterous.

Some few instances have been recorded of earwigs being carnivorous, devouring the larvæ and pupæ of wild bees and even their own species, but the majority are in a normal state certainly eaters of vegetable matter, congregating under bark, and destroying flowers, fruit, &c., often to a considerable extent. An instance of their adaptability to circumstances is afforded by Mr H. W. Bates's discovery of a large white species (above referred to) very common on white sandy beaches of the Brazilian river Pará, at Caripi, with a white *Tetracha* and a white mole cricket, thus whiteness was permanent, and must not be confused with the light colour of recently disclosed individuals.

The female of the common earwig has long been noted for an exhibition of remarkable maternal instinct in defending her progeny, not only brooding over her eggs, but caring for her newly hatched young.

The chief writers on *Forficulidae* are Dohrn, in the *Stettiner entomologische Zeitung* for 1862 and following years, and quite recently, S. H. Scudder, in the *Proceedings of the Boston Natural History Society*, vol. xviii, the latter being the first to discuss these insects in a collective form. (E. C. R.)

EASEMENT, in English law, is a species of servitude or limited right of use over land belonging to another. It is distinguished from a *profit*, which is a right to take the soil of another, while an easement is a right to use the soil or the produce of the soil in a way tending to the more convenient enjoyment of another piece of land. Thus a right of way is an easement, a right of common is a profit. Besides rights of way the most important easements are *water-courses* (as where a person has a right to divert a flow of water), the right to discharge water, &c., upon a neighbour's land, and the right to restrain such a use of land as would obstruct the access of light and air to an ancient window.

EASTBOURNE, a watering-place on the Sussex coast, 66 miles from London by railway. It is situated about three miles to the east of Beachy Head, the loftiest headland on the English Channel. It once consisted of three parts:—the old village of East Bourne, a mile inland; South Bourne, lying back from the shore; and Seashouses, facing the beach; but these distinctions are now almost obliterated, and numerous handsome terraces and detached houses have more or less united the three old hamlets into one town. Besides the parish church of St Mary's, a building of some antiquity, there are four chapels of ease in Eastbourne. A pier was erected in 1868. The population, which is rapidly increasing, was 10,361 in 1871.

EASTER, the annual festival observed throughout Christendom in commemoration of the Resurrection of our Lord Jesus Christ. The word *Easter*—Anglo-Saxon, *Eastre*, *Eoster*; German, *Ostern*—like the names of the days of the week, is a survival from the old Teutonic mythology. According to Bede (*De Temp. Rat.*, c. xv.) it is derived from *Eostre*, or *Ostara*, the Anglo-Saxon goddess of spring, to whom the fourth month, answering to our April—thence called *Eostur-monath*—was dedicated. This month, Bede informs us, was the same as the "Mensis Paschalis," when "the old festival was observed with the gladness of a new solemnity."

Wing of Earwig

The name by which Easter is known among the Romance nations—French *pâques*; Italian, *pasqua*; Spanish, *pascua*—is derived through the Latin *pascha*, and the Greek *πάσχα*, from the Chaldee or Aramæan form, *ܢܚܕܐ*, *pasch'a*, of the Hebrew name of the Passover festival, *פסח*, *pesach*, from *פסח*, “he passed over,” in memory of the great deliverance when the destroying angel “passed over the houses of the children of Israel in Egypt when he smote the Egyptians,” Exod. xii. 27. An erroneous derivation of *pascha* is given by some of the early fathers of the church, e.g., Irenæus, Tertullian, &c., to whom Hebrew was an unknown tongue, from the Greek *πάσχειν*, “to suffer,” as being the period of our Lord’s sufferings. St Angustine (in *Joann. Tract* 55) notices this false etymology, and shows how similarity of sound had led to the error, and gives the true derivation.

There is no trace of the celebration of Easter as a Christian festival in the New Testament or in the writings of the apostolic fathers. The sanctity of special times or places was an idea quite alien from the early Christian mind, too profoundly absorbed in the events themselves to think of their external accidents. “The whole of time is a festival unto Christians because of the excellency of the good things which have been given,” writes Chrysostom, commenting on the passage 1 Cor. v. 7, which has been erroneously supposed to refer to an apostolic observance of Easter. Origen also in the same spirit (*Contr. Celsum*, viii. 22) urges that the Christian who dwells on the truths of Christ as our Passover and the gift of the Holy Ghost, is every day keeping an Easter and Pentecostal feast. The ecclesiastical historian Socrates (*Hist. Eccl.*, v. 22) states with perfect truth that neither Christ nor his apostles enjoined the keeping of this or any other festival. “The apostles,” he writes, “had no thought of appointing festival days, but of promoting a life of blamelessness and piety;” and he attributes the introduction of the festival of Easter into the church to the perpetuation of an old usage, “just as many other customs have been established.” This is doubtless the true statement of the case. The first Christians, being derived from, or intimately connected with, the Jewish Church, naturally continued to observe the Jewish festivals, though in a new spirit, as commemorations of events of which these had been the shadows. The Passover, ennobled by the thought of Christ the true Paschal Lamb, the first-fruits from the dead, continued to be celebrated, and became the Christian Easter. Thus the human instinct which everywhere craves for the commemoration of marked epochs in the personal, social, ecclesiastical, or national life, found its legitimate gratification in the public celebration of the events which are the foundation of the Christian faith.

But though the observance of the Paschal festival at a very early period became the rule in the Christian church, a difference as to the time of its observance speedily sprang up between Christians of Jewish and Gentile descent, which led to a long-continued and bitter controversy, and an unhappy severance of Christian union. No rule as to the date of the Easter festivals having been laid down by authority, Christians were left to follow their own instincts. These were naturally different in the Jewish and Gentile churches. The point at issue really was the date of the termination of the Paschal fast. With the Jewish Christians, whose leading thought would be the death of Christ as the true Paschal Lamb, this fast would end at the same time as that of the Jews, on the 14th day of the moon, at evening, and the Easter festival would immediately follow, entirely *irrespective of the day of the week*. With the Gentile Christians, on the other hand, unfettered by Jewish traditions, the first day of the week would be identified with the Resurrection festival, and the preceding

Friday would be kept as the commemoration of the Crucifixion, *irrespective of the day of the month*, the fast continuing with increasing strictness till the midnight of Saturday. With the one, therefore, the observance of the day of the month, with the other the observance of the day of the week, was the ruling principle. The chief point was the “keeping” or “not keeping” the 14th day of the moon corresponding to that of the month Nisan. Those who, adopting the Jewish rule, did so keep the 14th day were called *Τετραδεκάτηται*, *Τετράδιται*, *Quartodecimani*, and were stigmatized as heretics. In the absence of any authoritative decision as to the day to be observed and the proper mode of calculating it, other discrepancies arose, which led to controversies and dissensions which, in the words of Epiphanius (*Panar.*, Hæc. lxx.), distracted the church, and became a source of mockery and ridicule to the unbelievers. “Some,” he writes, “began the festival before the week, some after the week, some at the beginning, some at the middle, some at the end, thus creating a wonderful and laborious confusion.”

This diversity of usage was gradually brought to an end by the verdict of the Church of Rome. The Roman Christians adopted the ordinary Gentile usage, which, within certain limits, placed the observance of the Crucifixion on a Friday, and that of the Resurrection on the following Sunday. A decretal of Pope Pius I., c. 147—the genuineness of which, however, is by no means established—pronounces that “the Pasch should be celebrated on the Lord’s Day by all.” His successor Anicetus was equally firm upon the point. Polycarp, the venerable and sainted bishop of Smyrna, who, according to Irenæus (*apud Euseb.*, II. E., v. 24), visited Rome in 159 with this object, failed to induce Anicetus to conform to the Quartodeciman usage, which Polycarp had inherited from his master, the Apostle John. Anicetus declined to permit the Jewish custom in the churches under his jurisdiction, but made no scruple of communicating with those who adopted it, and allowed Polycarp to celebrate the Eucharist at Rome. Between thirty and forty years after this visit (197) the same question was controverted in a very different spirit between Victor, bishop of Rome, and Polycrates, bishop of Ephesus, the aged metropolitan of proconsular Asia. This province was the only portion of Christendom that still maintained the Quartodeciman usage, which had been dropt even by the churches of Palestine and Alexandria. Victor’s despotic demand that the Asiatic churches should adopt the Roman system having been met by Polycrates with a courteous but firm refusal, Victor proceeded to excommunicate him and all who held with him. So sweeping a measure shocked the Christian world. Irenæus remonstrated with the bishop of Rome, and ultimately the Asiatic churches were allowed to retain their usage unmolested. (Euseb., II. E., v. 23–25.) We still find the Quartodeciman usage springing up from time to time in various places, but it never took permanent root, and at the time of the Council of Nicæa (325) the Syrians and the Antiochenes were the solitary champions of the Jewish rule. The settlement of this controversy was one among the causes which led the emperor Constantine to summon that council. The consent of the assembled prelates was unanimous. All agreed that Easter should be kept on one and the same day throughout the world, and that none should hereafter follow the blindness of the Jews (Socr., II. E., i. 9). Nothing, however, was said as to the determination of the day. This was practically left to be calculated at Alexandria, the home of astronomical science, and the bishop of that see was to announce it annually to the churches under his jurisdiction and to the bishop of Rome, by whom it was to be communicated to the Western churches.

But although measures had thus been apparently taken to secure uniformity of observance, some centuries elapsed before all discrepancy ceased. A more intricate question remained to be solved, viz., how the full moon on which Easter depended was to be predicted. The Nicene decrees had effectually crushed the feeble remnants of the Quartodeciman usage. It was established as a rule that Easter must be kept on a Sunday, but there was no general agreement as to the cycle by which the festival was to be calculated,—some churches adopting one rule, some another. We learn from St Ambrose (*Epist.* 23) that in 387 the churches of Gaul kept Easter on March 21, while the churches of Italy postponed it to April 18, and those of Egypt a week later still, to April 25; and it appears from an epistle of Leo the Great (*Epist.* 64 *ad Marcian.*) that in 455 there was eight days' difference between the Roman and Alexandrine Easter. Similar discrepancies are mentioned by Gregory of Tours in the year 577, nor did they disappear from the Gallican Church till the 8th century, although by a canon of the fourth Council of Orleans (541) it had been ordained that the Easter festival should be kept at the same time by all, according to the tables of Victorius. The ancient British Church observed the 84 years' cycle which they had originally received from Rome, and their stubborn refusal to give it up caused much bitter controversy between the fathers of Iona and the Latin missionaries. These latter unfairly attempted to fix the stigma of the Quartodeciman heresy on their opponents, and they are sometimes even now spoken of as adopting the Asiatic mode of calculation, and false inferences are thence drawn as to the Eastern origin of the British Church. This, however, is quite erroneous. The early British and Irish Church always commemorated the Crucifixion on a Friday and the Resurrection on a Sunday. The only difference between them and the Romish Church was in the cycle adopted for the computation of the festival,—the British Church really adhering to the cycle originally adopted by the Romish Church itself, which had been superseded by the more accurate calculations of Victorius of Aquitaine (457), and of Dionysius Exiguus (525). This led to a double Easter being observed by the adherents of the two churches. Thus, as we learn from Bede (*Ecc. Hist.*, iii. 25), in 651 Queen Eanfleda, adopting the Roman rule, was fasting and keeping Palm Sunday while her husband Oswy, king of Northumbria, was celebrating the Easter festival. This diversity of usage was put an end to in the kingdom of Northumbria in the council of Streaneshalch, or Whitby (654); and the Roman rule was finally established in England by Archbishop Theodore in 669. This rule may be thus briefly stated: Easter day is the first Sunday after the 14th day (not the full moon) of the calendar moon which happens on or next after March 21. This calendar moon, however, is not the moon of the heavens, nor the mean moon of the astronomers, but an imaginary moon created for ecclesiastical convenience in advance of the real moon (see Prof. De Morgan's article in *Companion to the Almanac*, 1845). After nine centuries a fresh discrepancy in the observance of Easter between the Roman and the English Church was caused by the refusal in England to adopt the Gregorian reformation of the calendar, 1582, apparently for no other reason than that the alteration had originated at Rome. This difference was happily put an end to in 1752, when the "New Style" was adopted in the United Kingdom. The churches of Russia and Greece, and the Oriental churches generally, still observe the unreformed calendar, their Easter falling sometimes before sometimes after that of the Western church; very rarely, as in 1865, the two coincide.

The rules on which the calculation of Easter is based are given in the article *CALENDAR* (vol. iv. p. 675)

Easter day, as commemorating the central fact of our religion, has always been regarded as the chief festival of the Christian year, and has been from the earliest times observed with a stately and elaborate ceremonial. It is not, however, the purpose of this article to enter on the ritual observances of Easter, nor on the many curious and interesting popular customs—of which the sending of Pasch eggs, or Easter eggs, is one of the most wide-spread—with which it is connected in all Christian nations. For these last the reader may consult Brand's *Popular Antiquities*, Hone's *Every Day Book*, and Chambers's *Book of Days*. (E. v.)

EASTLAKE, SIR CHARLES LOCK (1793–1865), an eminent painter who became president of the Royal Academy in London, was born on 17th November 1793 in Plymouth, where his father, a man of uncommon gifts but of indolent temperament, was solicitor to the Admiralty and judge and advocate of the Admiralty Court. Charles was educated (like Sir Joshua Reynolds) at the Plympton grammar-school, and in London at the Charterhouse. Towards 1809, partly through the influence of his fellow-Devonian Haydon, of whom he became a pupil, he determined to be a painter, he also studied in the Royal Academy school. In 1813 he exhibited in the British Institution his first picture, a work of considerable size, Christ restoring life to the Daughter of Jairus. In 1814 he was commissioned to copy some of the paintings collected by Napoleon in the Louvre, he returned to England in 1815, and practised portrait-painting at Plymouth. Here he saw Napoleon a captive on the "Bellerophon;" from a boat he made some sketches of the emperor, and he afterwards painted, from these sketches and from memory, a life-sized full-length portrait of him, which was pronounced a good likeness; it belongs to the marquis of Lansdowne. In 1817 Eastlake went to Italy, in 1819 to Greece; in 1820 back to Italy, where he remained altogether fourteen years, sojourning chiefly in Rome and in Ferrara. Subjects of banditti and peasant-life engaged his pencil mostly from 1820 onwards. In 1827 he exhibited at the Royal Academy his picture of the Spartan Isidas—who (as narrated by Plutarch in the life of Agesilaus), rushing naked out of his bath, performed prodigies of valour against the Theban host. This was the first work that attracted much notice to the name of Eastlake, who in consequence obtained his election as A.R.A., in 1830, when he returned to England, as R.A. In 1830 he succeeded Shee as P.R.A. (his only worthy competitor being Landseer, with the elder Pickersgill and George Jones besides, to mark the poor estate of British art, or of its official representatives), and, as usual, he was knighted. Prior to this, in 1841, he had been appointed secretary to the Royal Commission for decorating the Houses of Parliament, and he retained this post until the commission was dissolved in 1862. In 1843 he was made keeper of the National Gallery, a post which he resigned in 1847 in consequence of an unfortunate purchase that roused much animadversion, in 1855, director of the same institution, with more extended powers. During his directorship he purchased for the gallery 155 pictures, mostly of the Italian schools. He became also a D.C.L. of Oxford, F.R.S., Chevalier of the Legion of Honour, and member of various foreign academies. In 1849 he married Miss Elizabeth Rigby, a lady of some literary distinction. In 1865 he fell ill at Milan; he died at Pisa on 24th December in the same year, and lies buried at Kensal Green.

As a painter, Eastlake was gentle, harmonious, diligent, and correct; lacking fire of invention or of execution; eclectic, without being exactly imitative, influenced rather by a love of ideal grace and beauty than by any marked bent of individual power or vigorous originality. Among

his principal works (which were not numerous, 51 being the total exhibited in the Academy) are:—1828, *Pilgrims arriving in sight of Rome* (repeated in 1835 and 1836, and perhaps on the whole his *chef d'œuvre*); 1829, *Byron's Dream* (in the National Gallery); 1834, the *Escape of Francesco di Carrara* (a duplicate in the National Gallery); 1841, *Christ Lamenting over Jerusalem* (ditto); 1843, *Hagar and Ishmael*, 1845, *Comus*; 1849, *Helena*; 1851, *Ippolita Torelli*; 1853, *Violante*; 1855, *Beatrice*. These female heads, of a refined semi-ideal quality, with something of Venetian glow of tint, are the most satisfactory specimens of Eastlake's work to an artist's eye. He was an accomplished and judicious scholar in matters of art, and published, in 1840, a translation of Goethe's *Theory of Colours*, in 1847 (his chief literary work) *Materials for a History of Oil-Painting*, especially valuable as regards the Flemish school; in 1848, *Contributions to the Literature of the Fine Arts*; in 1851 and 1855, translated editions of Kugler's *History of the Italian School of Painting*, and *Handbook of Painting*.

Sir Charles Eastlake was a man of middle height, spare form, reddish complexion, bright hair (scanty in advanced life); of unassuming and rather courtier-like bearing; reluctant to oppose or offend, but with a strong sense of official duty. He was a neat and appropriate speaker, and filled his presidential and other offices with great credit in the eyes of all who appreciate moderation and cultured finish in the speech and bearing of a public man.

EASTON, a borough of the United States, and capital of Northampton county, Pennsylvania, is situated on the right bank of the Delaware immediately above the confluence of the Lehigh, 54 miles north of Philadelphia. The town is very systematically arranged in spite of the irregularity of the ground on which it is built; the water supply from the Lehigh river is abundant, and a strong pressure is obtained by the elevated position of the reservoirs. As the centre of a rich agricultural and mineral district, with free communication both by land and water, Easton has considerable activity at once in trade and manufacture. Among its establishments the borough contains breweries, tanneries, carriage factories, iron foundries, a rope-walk, and an oil-factory; and South Easton, on the other side of the Lehigh, has a cotton-factory, a rolling-mill, and railway engineering works. The principal buildings are the farmers' and mechanics' institute, the free reading room, and the Presbyterian or Lafayette college, which was founded in 1831, and in 1872 had 25 teachers and 259 students. The borough, laid out in 1738, was incorporated in 1789. Population in 1870, 10,987; or, if South Easton be included, 14,154.

EAST SAGINAW, a city of Saginaw county, Michigan, United States, is situated on the Saginaw river, about 90 miles N.N.W. of Detroit. It extends about three miles along the river, with a breadth of nearly a mile. It is the principal depot of the salt and lumber trade of the Saginaw valley, and possesses foundries, boiler-shops, saw-mills, and shingle-mills. It is the terminus of the Saginaw Valley and St. Louis Railway, while a branch of the Flint and Pere Marquette Railway radiates here to Bay city and another to Caro, Tuscola county. On the opposite bank of the river is the Jackson, Lansing and Saginaw line. East Saginaw was incorporated as a village in 1855, and obtained a city charter in 1859. Population in 1870, 11,350.

EAU DE COLOGNE, a perfume, so named from the city of Cologne, where its manufacture was first established by an Italian, Giovanni Maria Farina, born in 1655, and by other members of his family, some of whom made it according to a method due to one Paul Feminis. In 1874 there were in Cologne 35 establishments for the preparation of the perfume, 28 of which were in the hands of persons

bearing the name of Farina. Eau de Cologne consists of a solution of various essential oils in strong alcohol. The purity and thorough blending of the ingredients are of the greatest importance in the process of manufacture. It was originally prepared by making a spirituous infusion of certain flowers, pot-herbs, drugs, and spices, and adding thereto, after distillation, definite quantities of several vegetable essences. See Laboulaye, *Dictionnaire des Arts et Manufactures*, vol. ii. s.v. "Parfumerie."

EBEL, HERMANN WILHELM (1820–1875), a distinguished philologist, was born at Berlin, May 10, 1820. He displayed in his early years a remarkable capacity for the study of languages, and at the same time a passionate fondness for music and poetry. At the age of sixteen he became a student at the university of Berlin, applying himself especially to philology, and attending the lectures of Boeckh. Music continued to be the favourite occupation of his leisure hours, and he pursued the study of it under the direction of Marx. In the spring of 1838 he passed to the university of Halle, and there began to apply himself to comparative philology under Pott. Returning in the following year to his native city, he continued this study as a disciple of Bopp. He took his degree in 1842, and, after spending his year of probation at the French Gymnasium of Berlin, he resumed with great earnestness his language studies. About 1847 he began to study Old Persian. In 1852 he accepted a professorship at the Beheim-Schwarzbach Institution at Filehne, which post he held for six years. It was during this period that his studies in the Old Slavic and Celtic languages began. In 1858 he removed to Schnedeimühl, and there he discharged the duties of first professor for ten years. He was afterwards called to the chair of comparative philology at the university of Berlin. The most important work of Dr Ebel in the field of Celtic philology is his revised edition of the *Grammatica Celtica* of Professor Zeuss, completed in 1871. This had been preceded by his treatises—*De rebus Britannici futuro ac conjunctivo* (1866), and *De Zeussii curis positae in Grammatica Celtica* (1869). He made many learned contributions to Kühn's *Zeitschrift für vergleichende Sprachforschung*, and to Schleicher's *Beiträge zur vergleichenden Sprachforschung*; and a selection of these contributions was translated into English by Sullivan, and published under the title of *Celtic Studies* (1863). Ebel contributed the Old Irish section to Schleicher's *Indogermanische Chrestomathie* (1869). Among his other works must be named *Die Lehnwörter der Deutschen Sprache* (1856). He died at Misdroy, August 19, 1875.

EBERHARD, surnamed IM BART (*Barbatus*), count and afterwards first duke of Würtemberg, was born December 2, 1445. He was the second son of Count Ludwig I., who died in 1450; and he succeeded his elder brother, Ludwig II., at the age of twelve (1457). The guardianship of the young count was assumed by his uncle, Count Ulrich, and he had for tutor the learned John Naclerus. Coveting power and careless of learning, he profited little by the learning of his tutor; and at the age of fourteen he succeeded in throwing off the restraint of the guardianship, and assumed the government. But instead of discharging its duties he thought only of indulging his passions, and for a time led a wild, reckless life. By some means he was brought to serious reflections, and we find him, according to a custom which had not become wholly extinct, undertaking in 1468 the pilgrimage to Jerusalem. He also visited Italy, and made acquaintance with some of the most famous scholars of the age. His marriage with Barbara, daughter of Lodovico di Gonzaga, contributed to the amendment and elevation of his character. He began to study and to take a practical interest in the promotion of the new learning, and at the instigation of his wife he founded, in 1477, the university of Tübingen. Hither came, in 1481,

the young advocate John Reuchlin, who lectured on Greek at the university and took his degree of doctor of laws. Count Eberhard conceived a great liking for him, appointed him his private secretary, and named him councillor. In the spring of 1482 Eberhard, accompanied by Reuchlin, visited Rome, had an audience of Pope Sixtus IV., and received from him the Golden Rose. On his return he visited Florence, and enjoyed the society of the group of scholars gathered around Lorenzo de' Medici. It was in the same year that Eberhard, by the treaty of Minzingen, put an end to the evils which had arisen from a division of the county made in 1437 between his father and his uncle Ulrich, as representatives of the two lines of Urach and Stuttgart, and secured the future indivisibility of Wurtemberg, and the right of primogeniture in his own family. The treaty was made under the guarantee of the empire, and was sanctioned by an assembly of prelates, knights, and landed proprietors. By a limitation of the power of the prince agreed to at the same time, Count Eberhard became the founder of the constitution of Wurtemberg. He made Stuttgart his place of residence, and retained Reuchlin in his service till his own death. Eberhard sympathized with the desire that was daily strengthening for a thorough reformation in the church; and in his own dominions he rendered great services by his regulation of convents. Some of these institutions he secularized. Though a lover of peace, he knew how to bear the sword when war was necessary; and by his courage, wisdom, and fidelity to his engagements he secured the esteem and friendship of the emperors Frederick III. and Maximilian I., as well as that of other princes of his time. He was one of the leading members of the Grand Swabian League formed in 1488, and took part in the liberation of Maximilian, then king of the Romans, from his imprisonment at Bruges. In recognition of his great services the emperor at his first diet, held at Worms in 1495, raised Eberhard, without any solicitation on his part, to the dignity of duke, confirming at the same time all the possessions and prerogatives of his house. Duke Eberhard did not live long to enjoy his new dignity. He died at Tübingen on the 25th of February 1496. He had two children by his marriage; but these died in their infancy, and with him the line of Urach became extinct.

EBERHARD, AUGUST GOTTLÖB (1769-1845), a German poet and miscellaneous writer, was born at Belzig, near Wittenberg, in 1769, and died at Dresden on the 13th May 1845. He studied theology at Leipzig; but some stories he contributed to periodicals having proved successful, he devoted himself to literature. Among his earlier works were *Ida's Blumenkorbchen* (1792); *List um List, oder was ein Kuss nicht vermag*, *Ferdinand und Werner, der arme Flötenspieler* (1802); *Prinz Fiet Eloff* (1804); and *Ischariot Krall's Lehren und Thaten* (1807). For a time he was associated with Becker in the editorship of his *Taschenbuch* and his *Erholungen*, for both of which he wrote numerous tales and sketches. His claim to permanent literary fame, however, depends almost exclusively on his *Hannchen und die Küchlein* (1822), a charmingly graceful narrative poem in ten parts, which has passed through many editions, and been translated into most of the languages of Europe. An English translation by James Cochrane was published in 1854. In his *Der Erste Mensch und die Erde* (1828), a poem written in hexameters, the narrative of the creation is given with dignity and spirit. After the death of Vater in 1826, Eberhard succeeded to the editorship of the *Jahrbuch der häuslichen Andacht*, a well-known German educational annual. The miscellaneous poems (*Vermischte Gedichte*) of Eberhard appeared in two volumes in 1833, and his collected works (*Gesammelten Schriften*) in 20 volumes in 1830-1.

EBERHARD, JOHANN AUGUSTUS (1739-1809), an eminent German theologian and philosopher, was born at Halberstadt, in Lower Saxony, August 31, 1739. His father, a man of considerable literary attainments, was the singing-master at the church of St Martin's in that town, and also teacher of the school of the same name. Young Eberhard was educated partly at home and partly in his father's school. In the seventeenth year of his age he went to the university of Halle to study theology. Towards the end of 1759 he returned to his native town, and became tutor to the eldest son of the Baron Von der Horst, to whose family he attached himself for a number of years. In 1763 he was appointed con-rector of the school of St Martin's, and second preacher in the Hospital Church of the Holy Ghost; but he soon afterwards resigned these offices, and followed his patron to Berlin. The advantage he enjoyed of being introduced by the baron into the best company tended to polish his manners, and to form, even at an early period, a style of writing which served as a model to many of his contemporaries. His residence at Berlin gave him an opportunity of extending his knowledge, and of cultivating the acquaintance of some of the most eminent literary men in Germany. Amongst these were Nicolai and Moses Mendelssohn, with whom he associated upon terms of intimate friendship.

In 1768 he accepted the situation of preacher or chaplain to the workhouse at Berlin, along with that of preacher in the neighboring fishing village of Stralow. The income from these livings was small, but his object was to continue at Berlin, and he had at the same time the promise of further preferment upon the first vacancy. He now applied with renewed ardour to the study of theology, philosophy, and history, the first fruits of which soon appeared in his *Neue Apologie des Sokrates* (1772), a work occasioned by an attack which was made on the sentiments contained in the fifteenth chapter of Marmontel's *Belshazzar* by Peter Hofstede, a clergyman of Rotterdam, who, with a misdirected industry, raked up the vices of the most celebrated characters in the pagan world, and maintained the patristic view that even their virtues were only *splendida peccata*. Eberhard stated the arguments for the broader view with great acuteness and learning, and is therefore entitled to rank as one of the founders of rationalistic theology in Germany. The *Apology* itself, which constitutes but a small part of the book, is esteemed a master-piece of clear, dignified, and persuasive eloquence. The whole work exhibits much reading and philosophical reflection, but the liberality of his reasoning gave great offence to many of the strictly orthodox divines of his time, and is believed to have obstructed his preferment in the church.

In 1774 he was appointed to the living of Charlottenburg; and he employed the leisure he had in this situation in preparing a second volume of his *Apology*, which appeared in 1778. In this he not only endeavours to obviate some objections which were taken to the former part, but continues his inquiries into the doctrines of the Christian religion, religious toleration, and the proper rules for interpreting the Scriptures. Perceiving that his further promotion in the church would be attended with difficulty, he resolved, although reluctantly, to accept the situation of professor of philosophy at the university of Halle, which became vacant in 1778 by the death of G. F. Meier. As an academical teacher, however, he was unsuccessful. His powers as an original thinker were not equal to his learning and his literary gifts, as was shown in his opposition to the philosophy of Kant.

On his arrival at Halle, the philosophical faculty presented him with a diploma as doctor in philosophy and master of arts. In 1786 he was admitted a member of the Berlin Academy of Sciences; and in 1805 the king of

Prussia conferred upon him the honorary title of a privy-councillor. In 1808 he obtained the degree of doctor in divinity, which was given him as a reward for his theological writings. He died January 6, 1809.

Eberhard's attainments in philosophy and literature were extensive and profound. He was master of the learned languages, spoke and wrote French with facility and correctness, and understood English, Italian, and Dutch. He had read a great deal, was thoroughly versed in the philosophical sciences, and possessed a just and discerning taste for the fine arts. He was a great lover of music, and was himself a proficient in the art.

The following is a list of his works—*Neue Apologie des Sokrates*, &c., 2 vols 8vo, 1772-8, *Allgemeine Theorie des Denkens und empfindens*, &c., Berlin, 1776, 8vo, an essay which gained the prize assigned by the Royal Society of Berlin for that year, *Von dem Begriff der Philosophie und ihren Theilen*, Berlin, 1778, 8vo,—a short essay, in which he announced the plan of his lectures on being appointed to the professorship at Halle; *Lobschrift auf Herrn Johann Thunmann Prof der Weltweisheit und Beredsamkeit auf der Universität zu Halle*, Halle 1779, 8vo; *Amyntor, eine Geschichte in Briefen*, Berlin, 1782, 8vo,—written with the view of counteracting the influence of those sceptical and Epicurean principles in religion and morals then so prevalent in France, and rapidly spreading amongst the higher ranks in Germany, *Ueber die Zeichen der Aufklärung einer nation*, &c., Halle, 1783, 8vo, *Theorie der Schönen Künste und Wissenschaften*, &c., Halle, 1783, 8vo, 3d ed 1790, *Vermischte Schriften*, Halle, 1784; *Neue Vermischte Schriften*, 1b 1786, *Allgemeine Geschichte der Philosophie*, &c., Halle, 1788, 8vo, 2d ed with a continuation and chronological tables, 1796, *Versuch einer Allgemeinen-Deutschen Synonymik*, &c., Halle and Leipzig, 1795-1802, 6 vols 8vo, long reckoned the best work on the synonyms of the German language (an abridgment of it was published by the author in one large volume 8vo, Halle, 1802), *Handbuch der Aesthetik*, &c., Halle, 1803-1805, 4 vols 8vo. Besides the works above mentioned, Eberhard contributed a number of small tracts and essays to various periodical and scientific publications, and translated several foreign works. He was also the editor of the *Philosophical Magazine*, Halle, 1788-1792, and of the *Philosophical Archives*, Halle, 1793-1795. These two periodical works, which are now little read, were instituted for the purpose of controverting the metaphysical principles of Kant, and of vindicating the doctrines of Leibnitz and Wolf. Frederik Nicolai published a memoir on the life and character of Eberhard, Berlin and Stettin, 1810, 8vo. See also K. H. Jordens, *Leben Deutscher Dichter und Prosaisten*.

EBERT, FRIEDRICH ADOLF (1791-1834), a very eminent bibliographer, was born at Taucha, near Leipzig, July 9, 1791. He received his early education partly from his father, preacher to the Georgenhaus at Leipzig, and partly at the Nicholas School. At the age of fifteen he was appointed to a subordinate post in the town library of Leipzig, in which his literary tastes, early awakened, were fostered and strengthened. He studied theology for a short time, first at Leipzig and afterwards at Wittenberg, but, by the advice of a friend, renounced it in favour of history. After the close of his academical studies, he made his appearance as an author by the publication in 1811 of a work on public libraries, and in 1812 of another work entitled *Hierarchie in religionem ac literas commoda*. In the following year he took part in the reorganization of the Leipzig University Library, and in 1814 was appointed secretary to the Royal Public Library of Dresden. The same year he published *F. Taubmann's Leben und Verdienste*, and in 1819 *Torquato Tasso*, a translation from Giuguené with annotations. Anxious to turn to good account the rich resources open to him in the Dresden library, he undertook the work on which his reputation chiefly rests, the *Allgemeines bibliographisches Lexikon*, the first volume of which appeared in 1821, and the second in 1830. This was the first work of the kind produced in Germany; but nevertheless it had a higher aim and a more scientific character than its non-German precursors. In 1823 Ebert was called to the post of chief librarian and professor at Breslau, and at the same time was offered that of librarian to the duke of Brunswick at Wolfenbüttel. He accepted

the latter. But early in 1825 he returned to Dresden as public librarian, he was soon after named private librarian to the king, and in 1828 chief librarian and aulic councillor. Among his other works are—*Die Bildung des Bibliothekars* (1820), *Geschichte und Beschreibung der Königl. öffentlichen Bibliothek in Dresden* (1822), *Zur Handschriftenkunde* (1825-27), and *Culturperioden des obersächsischen Mittelalters* (1825). Ebert was a contributor to various journals and encyclopædias, and took part in the editing of Ersch and Gruber's great work. He died at Dresden, November 13, 1834, in consequence of a fall from the ladder in his library a few days before.

EBINGEN, a town of Wurtemberg, in the circle of the Schwarzwald, on the Schmida, a left-hand tributary of the Danube, 22 miles south of Tübingen and 37 miles west of Ulm. It has rather more than 5000 inhabitants, who are engaged in woollen-weaving, stocking-weaving, hat-making, bleaching, and cattle-dealing.

EBIONITES, a Christian sect which was separated from the general Christian church about the end of the 2d century. The origin of the name has been much disputed, some deriving it from Ebion as the founder of the sect, and others from the Hebrew word (עֲבִיּוֹנִים) meaning poor. For the former opinion the authority of Tertullian is quoted, who makes references to the existence of such a person as Ebion, but as counterbalancing these references there has to be considered—1st, that Tertullian being careless and inaccurate, and having no knowledge of Hebrew, may have merely fallen into the error of assuming that the sect took its name from that of a person; 2d, that no mention is made of the existence of such a person either by Irenæus or by Origen, and that any references to him by Epiphanius and later writers are probably borrowed from Tertullian; and 3d, that the name Ebionites had a very general signification, and represented a natural Judaizing tendency which must have had a more comprehensive beginning than that originating in an individual influence. Those who derive the name from the Hebrew word explain it in two ways—as applicable either to the poverty of the doctrines of the Ebionites, or to the poverty of their circumstances. Undoubtedly the name was applied to them with the former significance by their enemies, but it is more probable that they employed in a bad sense a name already existing, than that they coined it to suit their purpose. That the term was originally applied to the circumstances of the Ebionites seems the only probable supposition, and the argument in support of it may be stated thus:—That the early Christians, both Jewish and heathen, were designated the poor; that the poverty of the Jewish Christians continued longer than that of the heathen Christians, and Origen states that they in particular were named the poor (Εβωναιοὶ χρηματίζουσιν οἱ ἀπὸ Ἰουδαίων τὸν Ἰησοῦν ὡς Χριστὸν παραδεξάμενοι); and that, as the Judaizing Christians came gradually to be the only Jewish Christians who required to be distinguished from the heathen Christians, they retained the name. The fathers show a very imperfect knowledge of the origin, history, and doctrines of the Ebionites, but there cannot be any doubt that at first all Judaizing Christians went under that name. In the New Testament there is evidence of the existence of such a party, though it had not then developed into a recognized sect. This apparently did not happen till after the second destruction of Jerusalem and the founding of the heathen colony of Ælia Capitolina, when the emperor Hadrian banished from the neighbourhood all Jews who still retained their national peculiarities. As to the particular opinions of the Ebionites the statements of the fathers are somewhat contradictory, and this for the threefold reason—that by the isolation of the Ebionites from the general church the information obtainable regarding them could only be imperfect, that under

the general name Ebionites a good many varieties of opinion are included, and that their opinions varied at different periods of their history. The term Ebionites is used by some writers to include the Nazarenes, who, while recognizing the binding obligation of the Mosaic law on all Jews, did not regard it as binding on heathen Christians (see NAZARENES); but at an early period the stricter Ebionites must have separated themselves from the Nazarenes, who soon became merged in the general church. Of Ebionites proper Origen distinguishes two classes—those who affirm and those who deny the miraculous birth of Jesus; and in this he is followed by Eusebius. The extreme Ebionites, according to Origen, were only distinguishable from common Jews by the acceptance of the moral teaching of Christ, while those Ebionites who admitted the miraculous birth of Christ did not recognize His divinity proper, but believed that with His human nature the spirit of an angel or archangel, or even of Adam, was incorporated. Both classes of Ebionites seem to have had these points in common.—1st, They emphasized the unity of God, 2d, they affirmed the universal obligation of the Mosaic economy; 3d, of the books of the New Testament they received as genuine only the gospel of St Matthew; 4th, they denounced St Paul as a separatist, and 5th, they believed that Jerusalem was yet to be the city of God, and some of them at least believed in Christ's millennial reign. In the time of Eusebius the Ebionites inhabited chiefly the coasts of the Dead Sea, but they dwelt also in Rome and Cyprus. They vanished from history in the end of the 4th or beginning of the 5th century.

The ancient authorities on the Ebionites are Irenæus, Hippolytus, Eusebius, Tertullian, Origen, and Theodoret. In modern literature there are—Gieseler, in *Stüdtlin und Tschurner's Archiv für alt- und neuere Kirchengeschichte*, vol. II, Leipzig, 1820; Credner in *Winer's Zeitschrift für wissenschaftl. Theologie*, Sulzbach, 1829; Baur, *De Ebionitarum origine et doctrina ab Essais repetenda* (Tübinger Osterprogramm von 1831); Hilgenfeld, *Die Clementinischen Recognitionen*, Jena, 1848; the article "Ebioniten" in Herzog's *Real-Encyclopædie*; and Mansel's *Gnostic Heresies of the First and Second Centuries*, London, 1876.

EBOLI, or EVOLI, a town of Italy, in the province of Principato Citeriore and district of Campagna, situated about thirteen miles from Salerno, on an elevated site commanding a fine prospect over land and sea. It has an ancient castle belonging to the princes of Angri, and its church of St Francis of Assisi contains a curious picture of the Crucifixion by Roberto di Oderisio. Between the town and the Silarus or Sele are the ruins of the ancient *Eburi*, a place of municipal rank, and the river is still spanned by a bridge of fine Roman construction. Population, 8947.

EBONY (ἔβερος), the wood of various species of trees of the genus *Diospyros* and natural order *Ebenaceæ*, found in the tropical parts of Asia and America. The best kinds are very heavy, are of a deep black, and consist of heart-wood only. On account of its colour, durability, hardness, and susceptibility of polish, ebony is much used for cabinet work and inlaying, and for the manufacture of pianoforte keys, knife-handles, and turned articles. Ceylon ebony is furnished by *D. Ebenum*, which grows in great abundance throughout the flat country west of Trincomalee. The tree is distinguished from others by the inferior width of its trunk, and its jet-black, charred-looking bark, beneath which the wood is perfectly white until the heart is reached (See Baker, *Eight Years' Wanderings in Ceylon*, p. 293, 1855). The wood is stated by Sir J. E. Tennent to excel that obtained from *D. reticulata* of the Mauritius and all other varieties of ebony in the fineness and intensity of its dark colour. Although the centre of the trees alone is employed, reduced logs 1 to 3 feet in diameter can readily

be procured. Much of the East Indian ebony is yielded by the species *D. Melanoxylon*, a large tree 8 to 10 feet in circumference, with irregular rigid branches; oblong or oblong-lanceolate, entire leaves, white flowers, having a 5-cleft calyx, and a round, pulpy berry, containing 2-8 seeds. The bark of the tree is astringent, and mixed with pepper is used in dysentery by the natives of India. The wood of *D. Ebenaster*, the species called by the Singhalese *Cadooberia*, is black, with rich brown stripes; it is not so durable and heavy as the true ebones. That of *D. tomentosa*, a native of North Bengal, is black, hard, and of great weight. *D. montana*, another Indian species, produces a dark wood, variegated with white-coloured veins. *D. quasita* is the tree from which is obtained the wood known in Ceylon by the name *Calamander*, derived by Pridham from the Singhalese *kalu-mundrie*, black-flowing. Its closeness of grain, great hardness, and fine hazel-brown colour, mottled and striped with black, render it a valuable material for veneering and furniture-making. Cochin-China ebony is believed to be the wood of a species of *Maba*, a genus of *Ebenaceæ*. What is termed Jamaica or West Indian ebony and probably also the green ebony of commerce are produced by *Bya Ebenus*, a leguminous tree or shrub, having a trunk rarely more than 4 inches in diameter, flexible spiny branches, and orange-yellow, sweet-scented flowers. The wood is greenish-brown in colour, heavier than water, exceedingly hard, and capable of receiving a high polish.

From the book of Ezekiel (xxvii. 15) we learn that ebony was among the articles of merchandise brought to Tyre, and Herodotus states (iii. 97) that the Ethiopians every three years sent a tribute of 200 logs of it to Persia. Ebony was known to Virgil as a product of India (*Geor.*, ii. 116), and was displayed by Pompey the Great in his Mithridatic triumph at Rome. By the ancients it was esteemed of equal value for durability with the cypress and cedar (see Pliny, *Nat. Hist.*, xii. 9, xvi. 79). According to Solinus (*Polyhistor*, cap. iv. p. 353, Paris, 1621), it was employed by the kings of India for sceptres and images, also, on account of its supposed antagonism to poison, for drinking-cups. The hardness and black colour of the wood appear to have given rise to the tradition related by Pausanias, and alluded to by Southey in *Thalaba*, i. 22, that the ebony tree produced neither leaves nor fruit, and was never seen exposed to the sun.

EBRO (in Latin *Iberus*), the principal river of Spain, rises in the Cantabrian Mountains, near Remosa, in the province of Santander, flows in a general south-east direction through Old Castile, Navarre, Aragon, and Catalonia, and falls into the Mediterranean about 80 miles south-west of Barcelona, in 40° 41' N. lat. and 0° 50' E. long, forming by its delta a very considerable excrescence on the otherwise regular outline of the coast. It has a total length of about 340 miles, and its drainage area is calculated at 31,445 square miles. Already a noble stream when it breaks through the pass of Horadada, it becomes navigable about Tudela, but its value as a means of communication is almost neutralized by the obstacles in its channel, and sea-faring vessels cannot proceed further up than Tortosa. The great Imperial Canal, commenced by the emperor Charles V., proceeds along the right bank of the river from a point about three miles below Tudela, to the monastery of Monte Terero, five miles below Saragossa, and the San Carlos Canal affords direct communication between Amposta at the head of the delta and the harbour of Los Alfaques. The principal tributaries of the Ebro are—from the right hand the Jalon with its affluent the Jiloca, the Huerva, the Aguas, the Martín, and the Guadalupe; from the left the Aragon, the Gallago, and the Segre with its elaborate system of confluent rivers.

ÉCARTE (French, *écarté*, separated, discarded), a game at cards, of modern origin, probably first played in the Paris *salons*, in the first quarter of the 19th century. It is a development of a very old card game called *la triomphe*, or French-ruff (*Académie des Jeux*, various editions, Cotton and Seymour, *Compleat Gamester*, various editions, and Paul Boiteau D'Ambly, *Les Cartes à jouer*, Paris, Hachette, 1854).

Écarté is generally played by two persons, but a pool of three may be formed, the player who is out taking the place of the loser, and the winner of two consecutive games winning the pool. At French *écarté* (but not at English) bystanders who are betting may advise the players, by pointing to the cards they desire them to play, and the loser of the game goes out and one of the *retrants* takes his place, unless the loser is playing *la chouette* (i.e., taking all the bets that are offered), when he does not have to resign his seat if he loses.

A pack of cards is used from which the small cards (from the two to the six both inclusive) are removed. The players cut for deal, the highest having the choice. The dealer gives five cards to his adversary and five to himself, by two at a time to each and by three at a time to each, or *vice versa*. The eleventh card is turned up for trumps. If it is a king, the dealer scores one.

The non-dealer then looks at his cards. If satisfied with them he plays, and there is no *discarding*, if not satisfied he *proposes*. The dealer may either *accept* or *refuse*. If he accepts each player discards face downwards as many cards as he thinks fit, and fresh ones are given from the undealt cards or *stock*, first to complete the non-dealer's hand to five, then to complete the dealer's. Similarly, a second proposal may be made, and so on, until one player is satisfied with his hand. If the dealer refuses the hand is played without discarding.

If the non-dealer announces that he holds the king of trumps, he scores one; and similarly, if the dealer holds the king and announces it, he scores one.

The non-dealer, being satisfied with his hand, leads a card. The dealer plays a card to it, the two cards thus played forming a *trick*. The winner of the trick leads to the next, and so on. The highest card of the suit led wins, the cards ranking king (highest), queen, knave, ace, ten, nine, eight, seven. Trumps win other suits. The second to play to a trick must follow suit if able, and must win the trick if he can, whether by trumping or otherwise.

The scores are for the king (as already explained), and for the majority of tricks. The player who wins three tricks scores one for the *point*, if he wins all five tricks, he scores two for the *vole*. If the non-dealer plays without proposing, or the dealer refuses the first proposal, and fails to win three tricks, the adversary scores two, but no more even if he wins the *vole*. The game is five up.

HINTS TO PLAYERS—The following hints, which merely touch on the elements of the play, may be of service to beginners.—

Shuffle thoroughly after every deal to prevent the cards packing in suits, otherwise the trump card is not unlikely to be of the same suit as those preceding it, which are in the dealer's hand. It is an act of courtesy to the adversary to shuffle your own pack well, to save him the trouble of making your cards.

Do not look at your hand when dealer, until after the non-dealer has decided whether he will propose or not. The countenance or manner, often betrays the nature of the hand.

Do not announce the king until in the act of playing your first card.

Propose quickly, as hesitation exposes the nature of the hand. In order to be quick, the hands which should be played without proposing, called *jeux de règle*, ought to be thoroughly known. They are as follows—

1. All hands with three trumps, whatever the other cards.
2. Hands with two trumps which contain also—

a Any three cards of one plain suit;

b Two cards of one plain suit, one being as high as a queen,

c Two small cards of one suit, the fifth card being a king of another suit,

d Hands intermediate between b and c, i.e., with higher cards in one plain suit, and lower in another, e.g., two trumps, knave, ace of one suit, and nine or eight of another, or ace, ten of one suit, and ten of another, or ten, nine of one suit, and knave of another;

e Three cards of different suits, as high as king, knave, and a small card, or cards of equal value in different suits, as king, ace, nine, or king, and two tens, or two queens; or queen, knave, ace, or three knaves.

3 Hands with one trump, which contain also—

a King, queen, knave of one suit, and a small card of another,

b Four cards of one suit headed by king,

c Three cards of one suit headed by queen, and queen of another suit.

4 Hands with no trump, which contain three queens or cards of equal value in different suits, e.g., four court cards.

5 Hands from which only two cards can be discarded without throwing a king or a trump.

Holding cards which make the point certain, propose, as you have the chance of a refusal, and one good card taken in may give you the *vole*. If you hold a *jeu de règle*, and one of the trumps is the king, it is generally right to propose, as your adversary, if he accepts, cannot then take the king. But, except in the case of the king, the value of the trumps does not affect the proposal hands, as the game is not to lead trumps originally (without the king), unless you have three, but to keep them for trumping, and for this purpose high trumps are no better than low ones.

When discarding, throw out all cards except trumps and kings.

If your adversary proposes you should accept, unless you are guarded in three suits (a queen being a sufficient guard), or in two suits with a trump, or in one suit with two trumps. Hence the rule not to discard two cards, unless holding the king of trumps, applies to the dealer.

The hands with which to refuse are the same as those with which to play without proposing, except as follows—

1 Two trumps and three cards of one plain suit should not be played unless the plain suit is headed by a court card.

2 One trump and a tierce major is too weak, unless the fifth card is a court card. With similar hands weaker in the tierce major suit, accept unless the fifth card is a queen.

3 One trump and four cards of a plain suit is too weak to play.

4 One trump and two queens is too weak, unless both queens are singly guarded.

5 One trump, queen of one suit, and knave guarded of another should not be played unless the queen is also guarded, or the card of the fourth suit is a court card.

6 One trump, a king and a queen, both unguarded, should not be played, unless the fourth suit contains a card as high as an ace.

7 Four court cards without a trump are too weak to play, unless they are of three different suits.

Refuse with three queens, if two are singly guarded, otherwise, accept.

Lead from your guarded suit, and lead the highest. An exception to this rule is with two small trumps, a guarded queen, and a small card of another suit, when the single card should be led.

When playing a weak hand after a refusal, with no hope of the point and fear of losing the *vole*, lead the strongest single card, unless you have a king.

If the strong suit led is not trumped, persevere with it, unless with king of trumps, or queen (king not having been announced), or knave, ace, when lead a trump before continuing your suit. Also, when playing for the *vole* with a weak trump and high cards, change the suit each time to avoid a ruff. Having made three tricks, then lead the trump.

You should not lead trumps at starting, even if your best suit, unless you hold king, or queen, knave, or knave, ace, with court cards out of trumps. Holding three trumps, the two best being in sequence, lead a trump.

If cards are refused, it is better to lead from two small cards in sequence, than from a high tenace.

If you have won two tricks, your opponent one, and you hold a trump and a plain card, lead the plain card; but if your adversary has won two tricks and you win the third, lead the trump.

If you make two tricks and have the queen and two small trumps (the king having been announced against you), by leading a small trump you must win the point.

The score has to be considered. If the dealer is at four, and the king is not in your hand nor turned up, play any cards without proposing which gave an even chance of three tricks, e.g., a queen, a guarded knave, and a guarded ten. The same rule applies to the dealer's refusal, but he ought to be protected in three suits, e.g., three knaves, or a knave and two guarded tens. At the adverse

score of four, and king not being in hand or turned up, any hand with one trump should be played, unless the plain cards are very small and of different suits. Further, the rule to ask for cards with the point certain does not hold at the adverse score of four, unless king is in hand or turned up.

If the non-dealer plays without proposing when he is four to three, and the dealer holds the king he ought not to mark it. The same rule applies to the non-dealer after a refusal, if the dealer is four to three.

At the score of non-dealer three, dealer four, the dealer should refuse on moderate cards, as the player proposing at this score must have a very bad hand.

At four a forward game should not be played in trumps, as there is no advantage in winning the vole.

LAW OF ÉCARTÉ—The following laws are abridged from the revised code adopted by the Turf Club—

Cutting—1. A cut must consist of at least two cards. Card exposed in cutting, fresh deal. **Dealing**—2. Order of distribution of cards, whether by three and two, or *vice versa*, once selected, dealer must not change it during game. If changed, or wrong number of cards dealt, non-dealer, before he looks at his hand, may claim fresh deal. 3. Dealer turning up more than one card, non-dealer, before looking at his hand, may select either for trump, or may claim fresh deal. If he has looked at his hand there must be a fresh deal. 4. Faced card discovered in pack before trump card is turned, fresh deal. 5. Dealer exposing own cards in dealing, no penalty, exposing non-dealer's cards, non-dealer, before looking at his hand, has option of fresh deal. 6. Deal out of turn, discovered before trump turned up, void, after, too late to rectify. 7. Misdeal discovered after trump card turned, and before proposing or playing, non-dealer has option of fresh deal. If deal stands, dealer cannot mark king turned up, and non-dealer having superfluous cards discards them, dealer having superfluous cards, non-dealer draws and looks at them, either having too few cards, hand is completed from stock. 8. Either player playing with wrong number of cards, adversary has option of fresh deal. **Marking king**—9. King turned up may be marked any time before trump card of next deal is turned: king in hand must be announced before playing first card, or if king is card first led by non-dealer before being played to, or cannot be marked; if king is card first played by dealer, it must be announced before he plays again. 10. Player announcing king when he has not got it, and playing a card without declaring error, adversary may correct score and have hand played over again. If offender wins point or vole that hand, he scores one less than he wins. **Proposing**—11. Proposal, acceptance, or refusal made cannot be retracted. **Discarding**—12. Cards discarded must not be looked at. 13. Either player taking too many cards, and mixing any with his hand, adversary may claim fresh deal. If deal stands, adversary draws superfluous cards, and may look at them if offender has seen any of the cards given. Non-dealer asking for less cards than he discards, dealer counts as tricks all cards that cannot be played to. Same rule for dealer, but if he discovers error before playing a card, he may complete hand from stock. 14. Dealer giving more or less cards than asked for, non-dealer may claim fresh deal. If deal stands, non-dealer with too many cards discards superfluous ones, with too few, has hand completed from stock. 15. Faced card in stock after discarding, players may look at it; it is put aside and next card given. 16. Cards exposed in giving cards to non-dealer, he has option of taking them or of having next cards, dealer exposing his own cards, no penalty. 17. Dealer turning up top card after giving cards, cannot refuse second discard. 18. Dealer accepting when too few cards in stock to supply both, non-dealer may take cards, and dealer must play his hand. **Playing**—19. Card led in turn cannot be taken up again. Card played to a lead can only be taken up prior to another lead, to save revoke or to correct error of not winning trick. Card led out of turn may be taken up prior to its being played to. 20. Player naming one suit and leading another, adversary has option of requiring suit named to be led. If offender has none, no penalty. 21. Player abandoning hand, adversary is deemed to win remaining tricks, and scores accordingly. **Revolving, and not winning trick**—22. For either of these offences same penalty as in law 10. **Incorrect packs**—23. Deal in which discovery made, void, preceding deals good. **By-standers**—24. If players declare to play English écarté, bystanders, betting or not, not allowed to make remarks or give advice, nor to play out game of player resigning. If bystander makes remark which affects score, player prejudiced may call on him to pay his stakes and bets. 25. At French écarté, those betting may correct score, give advice (by pointing only), or play game of player who resigns.

Van-Tenac et Louis Delanoue, *Traité du Jeu de l'Écarté*, Paris 1845 (translated in Bohn's *Handbook of Games* London, 1850), "Cavendish" *The Laws of Écarté*, adopted by the Turf Club, with a *Treatise on the Game* London, 1878. (H. J.)

ECBATANA (Greek, 'Εκβάτανα), or, as it is found in Æschylus, 'Αγβάτανα, a name applied by the classical writers to several and possibly to no fewer than seven distinct sites,—the capital of Media Atropatene, the capital of Media Magna, the citadel of Persepolis, a Syrian city on Mount Carmel, the Assyrian castle of Amadiyah, the Arsacidan stronghold of Europus, and the city of Ispahan. This diversity of application doubtless arises from the fact that the word was a descriptive epithet; but its derivation has not been ascertained, and it is even possible that under the Greek disguise we may have two totally distinct originals. According to the usual hypothesis the meaning is treasury or place of assemblage, from the Old Persian *hagmatan*. The Median use of the name is the only one of special moment, involving, as it does, a difficult question of identification. It has long been admitted on all hands that the modern Hamadan, a town of Persia at the foot of the Elvend Mountains, occupies the site and preserves the name of the great city of Ecbatana, which was the summer residence of the Persian kings from the time of Darius Hystaspis to the Greek conquest, and afterwards became the capital of the Parthian empire. But the further identification of this Ecbatana with the Ecbatana of Herodotus, still maintained by some authorities, has been disputed by Sir Henry Rawlinson, who locates the latter city at Takht-i-Suleiman, a conical hill about half-way between Hamadan and Tabriz, which agrees in its main topographical features with the Herodotean description, and is still covered with extensive ruins of ancient date. There it was at least possible for the Median monarch Deoces to surround his palace with seven concentric walls of different colours, rising one behind the other; but, if the site of Hamadan be adopted, this part of the account, recently shown by the similar arrangement at Borsippa to be so probable in itself, must be relegated to the region of myths. One or other of the cities is possibly mentioned in the Old Testament as Achmetha or Amatha, in the Apocrypha the name frequently occurs in the form of Ekbatana.

See Sir Henry Rawlinson's "Memoir on the site of the Atropatenean Ecbatana," in *Journ. of the Roy. Geogr. Soc.*, 1841, Canon G. Rawlinson's *Herodotus*, vol. i 1875, p. 226.

ECCARD, JOHANNES (1553–1611), a celebrated composer of church music, was born at Muhlhausen on the Unstrut, Prussia, in 1553. After having received his first musical instruction at home, he went, at the age of eighteen, to Munich, where he became the pupil of Orlando Lasso, one of the greatest masters of the Franco-Belgian school. In his company Eccard is said to have visited Paris, but in 1574 we find him again at Muhlhausen, where he resided for four years, and edited, together with Johann von Burgk, his first master, a collection of sacred songs, called *Crepundia sacra Helmboldi* (1577). Soon afterwards he obtained an artistic appointment in the house of Jacob Fugger, the great Augsburg banker, and in 1583 he became assistant conductor, and twelve years later first chapel-master, at Königsberg in Prussia. In 1608 he received a call to Berlin as chief conductor of the elector's chapel, but this post he held only for three years, owing to his premature death in 1611. Eccard's works consist exclusively of vocal compositions, such as songs, sacred cantatas, and chorales for four or five, and sometimes for seven, eight, or even nine voices. Their polyphonic structure is a marvel of art, and still excites the admiration of musicians. At the same time his works are instinct with a spirit of true religious feeling. They have indeed a religious and historic significance beyond their artistic value. The important position of music in the service of the Reformed churches is well known. It was derived from, and therefore appealed again to, the feelings of the people. Luther himself recognized the elevating influence of the art by

cultivating it with zeal and success. His setting of the beautiful words "Ein' feste Burg ist unser Gott" is still regarded by the Germans as their representative national hymn. Eccard and his school are in the same way inseparably connected with the history of the Reformation. Of Eccard's songs a great many collections are extant; for an enumeration of the old and rare editions the reader is referred to the works by Winterfeldt, who has devoted great care to the study of Eccard, and by Döring (*Choral-Lieder*, p. 47).

ECCELINO, or EZZELINO DA ROMANO (1194–1259), fourth of the name, a famous Ghibelline chief, was born April 25, 1194. The family traced its origin to Eccelin, a knight who about 1036 followed the emperor Conrad II. into Italy, and received from him among other fiefs that of Romano, in the neighbourhood of Padua. Eccelino IV. was the elder of the two sons of Eccelino III., surnamed the Monk, who divided his little principality between them in 1223, and died in 1235. In his youth Eccelino displayed the dauntless courage and the power of dissimulation which characterized him through life. In 1226, at the head of a party of Ghibellines, he got possession of Verona, and was appointed podestat. He became one of the most faithful servants of the great emperor Frederick II., who by a charter granted in 1232 confirmed him in his possessions. Four years later (1236) he invited Frederick to enter Italy to his assistance, and in August met him at Trent. Eccelino was soon after besieged in Verona by the Guelfs, and the siege was raised by the emperor. Vicenza was next stormed, and the government was given to Eccelino. In 1237 the latter marched against Padua, became master of the city by capitulation, and crushed the spirit of the people by remorseless cruelty. The same year he took part in the siege of Mantua, and made himself master of Treviso. On the return of Frederick to Italy he joined him with a large force, and contributed to the great victory over the Guelfs at Cortenuova (November). In the following year he strengthened his connection with the emperor by marriage with Selvaggia, his natural daughter. In 1239, after entering Padua with Frederick, he was excommunicated and declared deprived of his estates by the Pope. But he still went on fighting and augmenting his dominions and perpetrating such incredible cruelties that the emperor, it is said, would fain have been rid of him. Nevertheless Eccelino was among the auxiliaries of Frederick at the siege of Parma in 1247. At the time of Frederick's death, in 1250, Eccelino, who had been named vicar-imperial of all the districts between the Trentine Alps and the river Adige, had extended his authority from the Adriatic to the environs of Milan. He had married a second wife in 1249. At length (1256) a crusade against this foe of the church was proclaimed by Pope Alexander IV., and a powerful league was formed, which the Venetians joined. Padua was soon lost to him; but in 1258 he defeated the army of the league and reduced Brescia. In 1259 he was called to Milan by the Ghibelline party and attempted to march on the city. He was, however, encountered by his enemies at Cassano, September 16, 1259, and was severely wounded and taken prisoner. His troops then disbanded. The great leader was resolved not to survive his fall, nor would he make his peace with the church. He tore the bandages from his wounds, refused to take food, and died at Soncino, September 26, 1259. By the death of his brother Alberico about a year later the family became extinct, and their possessions were distributed among the conquerors. The character of Eccelino is thus drawn by Mr. Kington in his *History of Frederick the Second* (i. p. 503):—"He was bold, clear-sighted in politics, and staunch to the side he had chosen as his own. He had a most commanding intellect, and his counsels were sure not to be slighted. He was a

first-rate soldier, and could overawe his enemies with a glance. He was, however, superstitious, as many found to their cost. Covetous of power, he was unscrupulous as to the means by which it was won or kept. His merciless cruelty and his callousness to human suffering brand him as an enemy to mankind." In the *Divina Commedia* (*Inferno*, xii.) Eccelino is seen amongst those who expiate the sin of cruelty in the lake of blood in the seventh circle of hell.

ECCHELLENSIS, or ECHELLENSIS, ABRAHAM, a learned Maronite, whose surname is derived from Eckel in Syria, where he was born towards the close of the 16th century. He was educated at the Maronite college in Rome, and, after taking his doctor's degree in theology and philosophy, became professor of Arabic and Syriac in the college of the Propagandists. Called to Paris in 1630 to assist Le Jay in the preparation of his polyglot bible, he contributed to that work the Arabic and Latin versions of the book of Ruth and the Arabic version of the third book of Maccabees. A quarrel with Gabriel Sionita, one of his coadjutors, whose work he had revised, led to a sharp controversy in which De Flavigny took part. He returned to Rome in 1642, but resumed his residence in Paris in 1645. Being invited by the Congregation of the Propaganda to take part in the preparation of an Arabic version of the Scriptures, he went again in 1652 or 1653 to Rome, where he died in 1664. Ecchellensis published several Latin translations of Arabic works, of which the most important was the *Chronicon Orientale* of Ibu-ar Râhib (Paris, 1653). He was engaged in an interesting controversy with Selden as to the historical grounds of episcopacy, in the course of which he published his *Eutychius Findicatus, sive Responsio ad Selden Origines* (Rome, 1661). Conjointly with Borelli he wrote a Latin translation of the 5th, 6th, and 7th books of the *Conics* of Apollonius of Perga (1661).

ECCLES, a populous village of England, in the county of Lancaster, four miles west of Manchester by railway, and practically an outlying suburb of that city. The parish church of St Mary, an ancient structure, was enlarged and extensively repaired in 1863–4; and several dissenting places of worship have been built in the present century. The cotton-manufacture is extensively carried on in the immediate neighbourhood. Previous to the Reformation the monks of Whalley Abbey had a grange at what is still called Monks' Hall; and in 1864 many thousands of silver pennies of Henry III. and John of England and William I. of Scotland were discovered near the spot. Ainsworth, the author of the Latin and English dictionary so long familiar to English students, was born at Eccles in 1660; and it was at the vicarage that the Right Hon. William Huskisson expired on 15th September 1830 from injuries received at the opening of the Liverpool and Manchester Railway.

ECCLESIA, in Grecian antiquity, the general assembly of Atheuian citizens, who met from time to time to discuss public affairs. Ecclesiæ were of two kinds, ordinary and extraordinary. The first of these were held, according to the laws of Solon, four times in each prytany, or period of thirty-five days; while the others were only summoned on some pressing emergency. When any measure of unusual importance was to be publicly debated, the people were summoned from the country by special messengers. An assembly thus convened was called a *catartesia*. Much discussion has taken place as to the exact days of the month on which the ecclesiæ were held; but the result has only been to prove either that there were no days invariably fixed for them, or that we have no data by which to determine accurately what these days were. In Ulpian it is stated that when there were three assemblies a-month, the first fell on the eleventh, the second on the twentieth, and

the third about the thirtieth of the month. The likelihood is that they were held at regular intervals though the days were not absolutely fixed. Ecclesiae were originally held in the Agora or Forum. The place of meeting was subsequently removed to the Pnyx, and afterwards to such of the greater temples as might be most convenient. The Pnyx lay to the west of the Areopagus, and commanded an extensive view. It was partly within the city walls, and had an area of about 12,000 square yards. On its northern side, cut out of the solid rock, was the *bema* or hustings from which the speakers addressed the people. From this tribunal a splendid view of the principal buildings of the city might be had. The right of assembling the people lay with the prytanes, or presidents of the senate or Council of Five Hundred, who both advertised beforehand the business to be discussed, and on the day of meeting sent round a crier to remind the citizens that their presence was required. In times of war, however, or other national crises, the generals of the army sometimes assumed this privilege, though it was necessary for them in doing so to give notice of their intention by a public proclamation. They also sometimes claimed the right of preventing the ecclesia from assembling; but their claims to this privilege were not generally recognized. Such of the citizens as refused to attend were fined, and six magistrates called *lexiarchs* were appointed to collect the fines. To assure a full meeting, the custom was ultimately introduced of paying the poorer classes a small sum for their attendance. This sum was originally an obolus, but after the time of Pericles it was raised to three. According to the usual order the proceedings of an ecclesia were commenced by a lustration or ceremonial purification of the place of assembly. The victims sacrificed were usually sucking pigs, whose blood was sprinkled round the boundary of the assembly. The crier next offered up a prayer to the gods for guidance, after which the business for which the assembly had been convened was introduced. According to the laws of Solon, the crier first called upon citizens above fifty years of age to speak and then upon all others; but this distinction was afterwards abolished, and the discussion was open from the commencement to all citizens of whatever age. The vote was generally taken by show of hands. In certain special cases, however, such as those affecting individual rights, the ballot was used. The decision to which the assembly came was called a *prophisma*. The ecclesia was sometimes adjourned from one day to the next, and it generally broke up at once if any of those present declared that he had seen an unfavourable omen or if thunder and lightning occurred. The word *ecclesia* came to mean any assembly regularly convened, and in New Testament Greek it is used to denote the assembly of Christians in any particular place, or the Christian church.

ECCLESIASTES, THE BOOK OF, has been handed down by Hebrew tradition as one of the three canonical books of Solomon, son of David, the other two being Proverbs and the Song of Songs, or Canticles.

Two different practices have obtained from time immemorial as to the position of this book in the Bible. According to one, which is preserved in the MSS. and editions of the Septuagint, and is followed by the MSS. and editions of the Vulgate, Ecclesiastes is the second in the order of the five books which, according to the Alexandrian Jews and the Greek and Latin churches, was written by Solomon. The order of these five books in the Alexandrian and Sinaitic Codices and in the MS. Bible of Charles the Bold, circa 850 (British Museum) is Proverbs, Ecclesiastes, Canticles, Wisdom, and Ecclesiasticus. According to the other practice the book in question is separated from those which are supposed to belong to the same author, and is joined for liturgical purposes to the other four Megilloth.

Thus in the oldest dated MS. of the entire Hebrew Bible yet known (1009), now in the imperial library of St. Petersburg, it is the *third* of the five Megilloth, viz., Ruth, Canticles, Ecclesiastes, Lamentations, and Esther. Though this order is also to be found in the Spanish and Italian MSS., it is by no means universal. Additional MS. 15,250 of the British Museum not only puts Ecclesiastes before Canticles, but places Ruth before the Psalms. In the fourteen pre-Reformation German translations of the Bible (1462–1518), and in Wycliffe's English version, where the five Solomonic books are still kept together, the order of the Septuagint and Vulgate is followed, as is also the case in the English Catholic version (Douai, 1610). Luther, who was the first to remove Wisdom and Ecclesiasticus from this group, and place them with the other so-called Apocryphal books at the end of the Old Testament, has left Ecclesiastes as second in the order of the Solomonic writings. In our first English translation of the entire Bible (1535) Coverdale followed the example of the great Continental Reformer. Hence this narrower group and this position of Ecclesiastes in the succeeding English Bibles, and in the present Authorized Version.

There is hardly another book in the Bible which has called forth so many commentaries and suffered as much at the hands of expositors as Ecclesiastes. Nearly 350 years ago Luther remarked,—“Difficult as this book is, it is almost more difficult to clear the author of the visionary fancies palmed upon him by his numerous commentators than to develop his meaning.” What would this sagacious Reformer have said if he could have seen the countless speculations of which it has been the subject since his days? We are positively assured that the book contains the holy lamentations of Solomon, together with a prophetic vision of the splitting up of the royal house of David, the destruction of the Temple, and the Captivity; and we are equally assured that it is a discussion between a refined sensualist and a sober sage. Solomon publishes in it his repentance, to glorify God and to strengthen his brethren, he wrote it “when he was irreligious and sceptical during his amours and idolatry.” “The Messiah, the true Solomon, who was known by the title of son of David, addresses this book to the saints;” a profligate who wanted to disseminate his infamous sentiments palmed it upon Solomon. It teaches us to despise the world with all its pleasures, and flee to monasteries; it shows that sensual gratifications are men's greatest blessing upon earth. It is a philosophic lecture delivered to a literary society upon topics of the greatest moment, it is a medley of heterogeneous fragments belonging to various authors and different ages. It describes the beautiful order of God's moral government, showing that all things work together for good to them that love the Lord; it proves that all is disorder and confusion, and that the world is the sport of chance. It is a treatise on the *summum bonum*; it is “a chronicle of the lives of the kings of the house of David from Solomon down to Zedekiah.” Its object is to prove the immortality of the soul; its design is to deny a future existence. Its aim is to comfort the unhappy Jews in their misfortunes; and its sole purport is to pour forth the gloomy imaginations of a melancholy misanthrope. It is intended “to open Nathan's speech (1 Chron. xvii.) touching the eternal throne of David,” and it propounds by anticipation the modern discoveries of anatomy and the Harveian theory of the circulation of the blood. “It foretells what will become of man or angels to eternity;” and, according to one of the latest and greatest authorities, it is a keen satire on Herod, written S. B. C., when the king cast his son Alexander into prison.¹

¹ For an historical account of the interpretation of Ecclesiastes, with detached specimens of these conflicting views, see Gussburg, *Commentary on Ecclesiastes*, pp. 27–293, London, 1861.

cultivating it with zeal and success. His setting of the beautiful words "Ein feste Burg ist unser Gott" is still regarded by the Germans as their representative national hymn. Eccard and his school are in the same way inseparably connected with the history of the Reformation. Of Eccard's songs a great many collections are extant; for an enumeration of the old and rare editions the reader is referred to the works by Winterfeldt, who has devoted great care to the study of Eccard, and by Döring (*Choral-kunde*, p. 47).

ECCELINO, or EZZELINO DA ROMANO (1194–1259), fourth of the name, a famous Ghibelline chief, was born April 25, 1194. The family traced its origin to Eccelin, a knight who about 1036 followed the emperor Conrad II. into Italy, and received from him among other fiefs that of Romano, in the neighbourhood of Padua. Eccelino IV. was the elder of the two sons of Eccelino III., surnamed the Monk, who divided his little principality between them in 1223, and died in 1235. In his youth Eccelino displayed the dauntless courage and the power of dissimulation which characterized him through life. In 1226, at the head of a party of Ghibellines, he got possession of Verona, and was appointed podestat. He became one of the most faithful servants of the great emperor Frederick II., who by a charter granted in 1232 confirmed him in his possessions. Four years later (1236) he invited Frederick to enter Italy to his assistance, and in August met him at Trent. Eccelino was soon after besieged in Verona by the Guelphs, and the siege was raised by the emperor. Vicenza was next stormed, and the government was given to Eccelino. In 1237 the latter marched against Padua, became master of the city by capitulation, and crushed the spirit of the people by remorseless cruelty. The same year he took part in the siege of Mantua, and made himself master of Treviso. On the return of Frederick to Italy he joined him with a large force, and contributed to the great victory over the Guelphs at Cortenuova (November). In the following year he strengthened his connection with the emperor by marriage with Selvaggia, his natural daughter. In 1239, after entering Padua with Frederick, he was excommunicated and declared deprived of his estates by the Pope. But he still went on fighting and augmenting his dominions and perpetrating such incredible cruelties that the emperor, it is said, would fain have been rid of him. Nevertheless Eccelino was among the auxiliaries of Frederick at the siege of Parma in 1247. At the time of Frederick's death, in 1250, Eccelino, who had been named vicar-imperial of all the districts between the Trentine Alps and the river Adige, had extended his authority from the Adriatic to the environs of Milan. He had married a second wife in 1249. At length (1256) a crusade against this foe of the church was proclaimed by Pope Alexander IV., and a powerful league was formed, which the Venetians joined. Padua was soon lost to him; but in 1258 he defeated the army of the league and reduced Brescia. In 1259 he was called to Milan by the Ghibelline party and attempted to march on the city. He was, however, encountered by his enemies at Cassano, September 16, 1259, and was severely wounded and taken prisoner. His troops then disbanded. The great leader was resolved not to survive his fall, nor would he make his peace with the church. He tore the bandages from his wounds, refused to take food, and died at Soncino, September 26, 1259. By the death of his brother Alberico about a year later the family became extinct, and their possessions were distributed among the conquerors. The character of Eccelino is thus drawn by Mr. Kington in his *History of Frederick the Second* (i. p. 503).—"He was bold, clear-sighted in politics, and staunch to the side he had chosen as his own. He had a most commanding intellect, and his counsels were sure not to be slighted. He was a

first-rate soldier, and could overawe his enemies with a glance. He was, however, superstitious, as many found to their cost. Covetous of power, he was unscrupulous as to the means by which it was won or kept. His merciless cruelty and his callousness to human suffering brand him as an enemy to mankind." In the *Divina Commedia* (Inferno, xii.) Eccelino is seen amongst those who expiate the sin of cruelty in the lake of blood in the seventh circle of hell.

ECHELLENSIS, or ECHELLENSIS, ABRAHAM, a learned Maronite, whose surname is derived from Eckel in Syria, where he was born towards the close of the 16th century. He was educated at the Maronite college in Rome, and, after taking his doctor's degree in theology and philosophy, became professor of Arabic and Syriac in the college of the Propagandists. Called to Paris in 1630 to assist Le Jay in the preparation of his polyglot bible, he contributed to that work the Arabic and Latin versions of the book of Ruth and the Arabic version of the third book of Maccabees. A quarrel with Gabriel Sionita, one of his coadjutors, whose work he had revised, led to a sharp controversy in which De Flavigny took part. He returned to Rome in 1642, but resumed his residence in Paris in 1645. Being invited by the Congregation of the Propaganda to take part in the preparation of an Arabic version of the Scriptures, he went again in 1652 or 1653 to Rome, where he died in 1664. Echellensis published several Latin translations of Arabic works, of which the most important was the *Chronicon Orientale* of Ibn-ar Râhib (Paris, 1653). He was engaged in an interesting controversy with Selden as to the historical grounds of episcopacy, in the course of which he published his *Eutychus l'indicatus, sive Responsio ad Seldeni Origines* (Rome, 1661). Conjointly with Eorelli he wrote a Latin translation of the 5th, 6th, and 7th books of the *Comics* of Apollonius of Perga (1661).

ECCLES, a populous village of England, in the county of Lancaster, four miles west of Manchester by railway, and practically an outlying suburb of that city. The parish church of St Mary, an ancient structure, was enlarged and extensively repaired in 1863–4; and several dissenting places of worship have been built in the present century. "It foretells what will become of man or angels to eternity;" and, according to one of the latest and greatest authorities, it is a keen satire on Herod, written S. C., when the king cast his son Alexander into prison.¹

¹ For an historical account of the interpretation of Ecclesiastes, with detached specimens of these conflicting views, see Gillsburg *Commentary on Ecclesiastes*, pp. 27–293, London, 1861.

One of the causes which have contributed to obscure the design of this book is the name *Ecclesiastes*. This title Preacher, which ascribes to Solomon an office foreign to the Old Testament, has been given to it by the Septuagint and Vulgate in accordance with a Jewish tradition, and has been adopted alike by the pre- and post-Reformation authorized versions of the Scriptures. The Jewish tradition in question is to be found in the *Midrash Rabba* on Eccl. i. 1, where we are told that "Solomon was called *Cohleth* = Ecclesiastes, because his discourses were delivered in the *Cahal* = Ecclesia." Hence the title in the Alexandrian version, which was followed by the Latin Authorized Version, and is reproduced in Wycliffe's Bible "the boc of Ecclesiastes, that is to sey, boc of talker to the people." Hence, too, Luther's title *Prediger*, which is followed in our first printed English Bible "the boke of the Preacher, otherwyse called Ecclesiastes" (Coverdale, 1535), and which is perpetuated in our Authorized Version. This title, however, is contrary to the grammatical form of the word *Cohleth*, as well as to the usage of the root from which it is derived. It has arisen from a desire on the part of the Jewish synagogue to exhibit Solomon in the garb of a penitent confessing his sins, and, by detailing his bitter experience, warning the people publicly to avoid the thorny path he has pursued and walk in the ways of righteousness. Landable as this desire is, it perverts the historico-exegetical import of the book, and is contradicted by the signification of the name.

Cohleth is the participle feminine Kal of *kāhal*, which primarily means to call, to call together, to collect, to assemble. The verb occurs about forty times in the Hebrew Bible, and is invariably used for assembling or gathering people together, especially for religious worship. Hence the name means a *collectress*, or an *assembleress of people into the presence of God, a female gatherer of an assembly to God*. This meaning of the name is fully confirmed by another Jewish tradition, which is embodied in the *Midrash Yalkut* (Eccl. i. 1), and is exhibited in the ancient Greek versions of Aquila and Symmachus. Chapter i. 12 tells us that Solomon is meant by this designation, since he was the only son of David who was king over Israel in Jerusalem. The feminine and symbolic appellation arises from the fact that in chapter vii. 27 of this very book Solomon is depicted as *personified Wisdom*, who appears herself in Prov. i. 10, viii. 1, &c., as *Cohleth*, or the *female gatherer of the people*. This symbolic name is, moreover, intended to indicate the design of the book itself, and to connect Solomon's endeavours here with his work recorded in 1 Kings viii. Solomon, who in 1 Kings viii. is described as *gathering* (קָהַל) the people to hold communion with the Most High in the place which he erected for this purpose, is here again represented as the *gatherer* (קָהַל) of the far-off people of God. As he retains his individuality, he sometimes describes his own experience, and sometimes utters the words of Wisdom, whose organ he is.

The design of this book, as indicated in the symbolic title of its hero, is to gather God's people, who were led astray by the inexplicable difficulties in the moral government of the world, into the community of God. *Cohleth* shows them the utter insufficiency of all human efforts to obtain real happiness—that it cannot be secured by wisdom, pleasure, industry, wealth, and prudence, but that it consists in the calm enjoyment of our lot, in resignation to the dealings of Providence, in the service of the Most High, and in looking forward to a future state of retribution, when all the present mysteries shall be solved, and when the Righteous Judge shall render to every man according to his deeds, whether they be good or evil.

Instead of writing an elaborate metaphysical disquisition

to refute the various systems of happiness which the different orders of mind and the different temperaments had constructed for themselves, Solomon is introduced as narrating his painful experience in all his attempts. He shows how he had vainly striven to divert the longings of his soul by various experiments, and the only solution which can pacify the perplexed mind when contemplating the unfathomable dealings in the moral government of the world.

The theme or problem of the book is given in chapter i. 2–11. On the assumption that there is *no hereafter*, and that the longingsoul is to be satisfied with the things *here*, *Cohleth* declares all human efforts to satisfy the longings of the soul to be utterly vain (chap. i. 1, 2), since conscious man is more deplorable than unconscious nature, for he must speedily quit this life, whilst the earth abides for ever (4), the objects of nature depart and retrace their course again, but man disappears and is for ever gone (5–11).

In corroboration of the allegation in the prologue, and to show the utter failure to satisfy the cravings of the soul with mere temporal pleasures, *Cohleth* tells us that, with all the resources of a great monarch at his command (chap. i. 12), he applied himself assiduously to discover by the *aid of wisdom* the nature of earthly pursuits, and found that they were fruitless (13–14), since they could not alter destinies. Hence, when he reflected upon the large amount of wisdom which he had acquired, he came to the conclusion that it is utterly useless (16–17), for the accumulation of it only increased his sorrow and pain (18). Wisdom having failed, *Cohleth* resolved to try *pleasure*, to see whether it would yield the desired happiness, but he soon found that this too was vain (chap. ii. 1), and hence denounced it (2). After procuring every imaginable pleasure (3–10) he found that it was utterly insufficient to impart lasting good (11). He then compared wisdom with pleasure, the two experiments he had made (12); and though he saw that the former had a decided advantage over the latter (13, 14a), still he also saw that it does not except its possessor from death and oblivion, but that the wise man and the fool must both die alike and be forgotten (14b–16). This melancholy thought made him hate both life and the wealth which he had acquired by wisdom and industry, and which, to aggravate matters, he perchance might leave to a reckless fool (17–21). It convinced him that man has nothing from his toil but wearisome days and sleepless nights (22, 23), and that there is therefore nothing better for man than to enjoy himself (24a). Soon, however, he found that this too is not in the power of man (24b, 25). God gives this power to the righteous and withholds it from the wicked, and it is after all only transitory (2).

Having shown the failure of wisdom, knowledge, and enjoyment to calm the distracted mind which broods over the problem that, whilst the objects of nature depart and retrace their steps, again man vanishes and is for ever forgotten, *Cohleth* now shows the vain efforts of industry to satisfy the restless longings of the soul. All the events of life are immutably fixed (chap. iii. 1–8); labour is therefore fruitless (9). Even the regulations to human labour which God has prescribed in harmony with this fixed order of things man in his ignorance often mistakes (10, 11). Nothing is therefore left but the enjoyments as one finds them. But this, too, as has already been shown, is a gift of God (12, 13), who has fixed everything to make man feel his utter dependence on and fear the Lord (14, 15). The success of the wicked does not militate against this conclusion, for there is a day fixed for righteous retribution (16, 17). But even if all terminates *here*, and man and beast have the same destiny (17–21), this only shows all the more that the enjoyment of life is our only portion

(22). Such a desperate conclusion, however, makes death preferable to a toilsome life (iv. 1-3),—a life spent in exertions to battle with the pre-ordained order of things, a life expended in labours which either arise from jealousies and fail in their end (4-6), or are prompted by avarice and defeat themselves (9-16). But as God has thus ordained the order of things, we ought to serve him (17-v. 6), trust to his protection under oppression (7, 8), and remember that the rich oppressor has not even the comfort of the poor labourer (9-11), and often brings misery upon his children and himself (12-16). This again brings Coheleth to the mournful conclusion that nothing is left but to enjoy the few fleeting years of life, which is a gift of God (17-19).

Coheleth now shows that neither the much-coveted wealth nor the highly-praised prudence suffices to secure the desired happiness and solve the melancholy problem of life that the same failure attends wealth (vi. 1-9), for the rich man cannot over-rule the order of Providence, nor forecast what will be for his happiness (10-12). The same is the case with the prudential or common sense view of life. Coheleth thought to secure happiness by acquiring and leaving a good name (vi. 1-4), by listening to merited rebuke (5-9), not indulging in a repining spirit. He would also submit to Divine Providence (10-14), be moderate in his religious practices (15-20), not meddle with the opinions of others (21, 22), seeing that higher wisdom is unattainable (23, 24), and submit to the oppressive powers that be, convinced that the mightiest tyrant will ultimately be punished (viii. 1-9), for, though righteous retribution is momentarily suspended which causes wickedness to triumph, God will eventually administer justice (10-13). But as he found that the fortunes of the righteous and the wicked *are often reversed all their lifetime*, he had to relinquish this common-sense view of life as utterly insufficient to calm the longings of the soul, and recurred to his repeated conclusion that there is nothing left for man but to enjoy the fleeting things of this life (14, 15).

Before propounding his final conclusion, Coheleth gives a *résumé* of his investigations. Since it is impossible to fathom the work of God by wisdom, seeing that even the righteous and wise are subject to this inscrutable Providence just as are the wicked (viii. 16-ix. 2);—for all must die alike and be forgotten, and have no more participation in what takes place here (3-6), and we are therefore to indulge in pleasures here, since there is no hereafter (7-10); success does not always attend the strong and the skilful (11, 12); wisdom, though advantageous in many respects, is often despised and defeated by folly (13-x. 3); we are to be patient under sufferings from rulers who by virtue of their power often pervert the order of things (4-7), since opposition may only increase our sufferings (8-11); the exercise of prudence will in the long run be more advantageous than folly (12-20); we are to be charitable, though the recipients of our charity often appear ungrateful, since some of them may after all requite us (xi. 1, 2); we are always to be at work, not allowing ourselves to be deterred by imaginary failures, since we know not which of our efforts may prove successful (3-6), and thus make life as agreeable as we can, since this is the only scene of enjoyment, and the future is all vanity (7, 8);—yet, seeing that even all this does not satisfy the higher craving of the soul, and still leaves conscious man in a more deplorable state than unconscious nature, for the objects of nature depart, retrace their course again, while man disappears and is for ever forgotten—Coheleth at last comes to the conclusion that the enjoyment of this life, combined with a belief in a future judgment, does secure real happiness for man (9, 10). We are therefore to live from our early years in the fear of God and of a final judgment, when the Righteous Judge will rectify all present inequalities (xii. 1-7).

The wisest and most painstaking Coheleth found by experience that all human efforts to obtain real happiness are vanity of vanities (xii. 8-10), that the sacred writings alone contain the clue to it (11, 12), that there is a Righteous Judge who takes cognizance of all we do, that He will in the great Day of Judgment try the conduct of us all, and that we are therefore to fear Him and keep His commandments (13, 14).

From this analysis of its contents it will be seen that the book consists of four parts, with a prologue and epilogue. The prologue and epilogue are distinguished by respectively beginning with the same phrase (i. 1, xii. 8) and ending with two marked sentences (i. 11, xii. 14). The prologue, which consists of chapter i. 1-11, propounds the grand problem of the book; whilst the epilogue, which consists of chapter xii. 8-12, gives the solution proposed by Coheleth. The four sections, which are respectively indicated by the recurrence of the same formula or refrain, viz. ii. 26, v. 19, and vii. 15, give the result of each experiment or group of efforts to satisfy the cravings of the longing soul, apart from the conclusion at which Coheleth arrived.

Coheleth fills up a gap in the Old Testament lessons Throughout the Hebrew Scriptures virtue and vice are spoken of as being visibly rewarded on earth. God declares at the very giving of the law that He will show mercy to thousands of those who love Him and keep His commandments, and visit the iniquity of those who hate Him to the third and fourth generation (Exod. xx. 5, 6). The whole of Lev. xxvi and of Deut. xxviii. are replete with promises of earthly blessings to those who will walk in the way of the Lord, and threatenings of temporal afflictions upon those who shall transgress His law. The faithful fulfilment of these promises and threatenings in the early stages of the Jewish history convinced every Israelite that "God judgeth the righteous, and God is angry with the wicked *every day*," and afforded a source of consolation to which the righteous resorted when the power of the wicked threatened destruction (1 Sam. xxiv. 13-16, xxvi. 23; Ps. vii. ix., li.). Like a net of fine threads is this doctrine spread over the entire Old Testament (comp. Ps. xvii. 1, 2; xxvi. 1, 2; xxviii. 1-3; xxxv; lv. 7-9; lv. 20-24; xc; cxii.; cxxv. 3; cxlvii.; cxi.; cxli. 10, Prov. x. 6; xi. 5-8, 19; xii. 7, Hag. ii. 15-20; Zeck. i. 2-6; viii. 9-17, Malachi ii. 17). By limiting the bar of judgment to this side of the grave, the Old Testament yielded no explanation of, or succour under, the distracting sight of the righteous suffering *all their life*, and then dying for their righteousness, and of the wicked prospering and prolonging their days through their wickedness. It was under such despairing circumstances that Psalms xxvii, xlix, and lxxiii were written. But these very Psalms endeavour to allay the prevailing scepticism in the moral government of God, by declaring that the righteous shall ultimately prosper and prolong their days *upon the earth*, and that the wicked shall suddenly be cut off in great misery. Hence the recurrence of this perplexity passing over into despair when these reassurances and consolations were not realized by experience, and when the sufferers, however conscious of their innocence, were looked upon as rejected of God in consequence of some secret sin. The book of Job, which so successfully combats the latter notion by showing that afflictions are not always a proper test of sin committed, only confirms the old opinion that the righteous are visibly rewarded here, inasmuch as it represents their calamities as transitory, and Job himself as restored to double his original wealth and happiness *in this life*.

Under the Persian and Ptolemaic dominion over Palestine, the political affairs of the Jews were such as to render the incongruity between the destinies of men and

their morals still more striking. Hence people began to arraign the character of God.

"Every one that doeth evil
Is good in the sight of Jehovah, he delighteth in them,
Or where is the God of justice?"—Mal. ii. 17.

"It is vain to serve God,
And what profit is it that we keep his ordinance
And walk mournfully before Jehovah of Hosts?
For now we pronounce the proud happy;
They also that work wickedness are built up;
They even tempt God, yet they are delivered."—Mal. iii. 17, 18.

Under these circumstances, when the inheritance of the Lord, which was to be the praise and the ruler of all the earth, was reduced and degraded to the rank of a mere province; when her inhabitants were groaning under the extortions and tyranny of hirelings; when her seats of justice were filled by the most venial and corrupt men (Eccl. iii. 16), when might became right, and the impunity and success with which wickedness was practised swelled most alarmingly the ranks of the wicked (viii. 10, 11); when the cherished faith in temporal retribution was utterly subverted by the melancholy experience of the reversion of destinies; when the longing minds of the desponding people, released from the terrors of the law, began to import as well as to construct philosophic systems to satisfy their cravings (xii. 12), and to resort to various other experiments to obtain happiness, Coheleth disclosed a new bar of judgment in the world to come. There the Judge of the quick and the dead will rectify all the inequalities which take place here.

On the Continent, where Biblical criticism has been cultivated to the highest degree, and where Old Testament exegesis has become an exact science, the attempt to prove that Solomon is not the author of Ecclesiastes would be viewed in the same light as adducing facts to demonstrate that the earth does not stand still. In England, however, some scholars of acknowledged repute still adhere to the Solomonic authorship. Their principal argument is that the unanimous voice of tradition declares it to be so. We at once concede the fact. The Jewish synagogue undoubtedly believed that Solomon wrote Canticles when young, Proverbs when in middle life, and Ecclesiastes in his old age (*Midrash Yalkut*, Eccl. i. 1), and the Christian church has simply espoused the Jewish tradition. But with all due deference, we submit that tradition has no authority whatever to determine points of criticism. It is an acknowledged fact that the ancients, both Jews and Christians, and indeed the leaders of thought to the beginning of the 16th century, had not the slightest appreciation of peculiarities of style. The different shades of meaning in which the same expression is used by different authors, the variations in forms, phrases, constructions, and sentences which obtained at diverse periods, and which supply definite data to philologists, and have been reduced to a science in modern days, began only to be noticed at the time of the Reformation, when the vital power of criticism was first applied to traditional dogmas. The spell of tradition once broken, thinking men soon began to recognize the literary style and the respective artistic merits of the component parts of the Bible. Hence Luther already declared, "Solomon did not write the book of Ecclesiastes; it was compiled by Sirach, at the time of the Maccabees . . . It is, like the Talmud, made up of many books, which perhaps belonged to the library of King Ptolemy Energetes in Egypt." No impartial student, with even a moderate knowledge of the genius of the Hebrew language, can fail to see the striking difference in the style of the pre- and post-exile books of the Old Testament. In the case of Ecclesiastes the difference is still more unmistakable. Of the vocabulary and phrases in Ecclesiastes a part is to be found in the post-Babylonian

biblical writings, and that only in the Chaldee portions; whilst another part has no parallel in the Bible, but is only to be met with in the Mishna, the Talmud, and other post-biblical productions. Unless, therefore, it is maintained that the Hebrew of the Bible, which extends over a period of several thousand years, and purports to exhibit the styles of a number of writers who lived in different districts, is unlike any other known literary language, that it had no development and no epochs in its literature, the striking Rabbinic complexion of Ecclesiastes must assuredly stamp it as the latest composition in the Old Testament. Those who know the ultra-orthodoxy of the eminent Hebrew scholar, Professor Delitzsch, will feel the convincing power of this fact when they find that he assigns to Ecclesiastes the latest date of any book in the Hebrew Bible, because it is written in this unquestionably late language. We have abstained from adducing any other arguments derived from its contents, because this appears superfluous. An intelligent reader even in the English translation can see that the representation of Coheleth as indulging in sensual enjoyments and acquiring riches and fame in order to ascertain what is good for the children of men (chap. ii. 3-9; iii. 12, 22, &c.), making philosophical experiments to discover the *summum bonum*, is utterly at variance with the conduct of the historical Solomon, and is an idea of a much later period; that the recommendation to individuals not to resent a tyrannical sovereign, but to wait for a general revolt (chap. viii. 2-9), would not proceed from King Solomon; that the complaint about the multiplication of profane literature (chap. xii. 12) could only have been made at a time when the Jews became acquainted with the Greek writings and Alexandrian philosophy. The book, however, is of Palestinian origin, as is evident from the frequent allusion to rain (xi. 3, xii. 2), which does not fall in Egypt; the reference to the Temple and its worship (iv. 7); and the mention of "the city" (viii. 10), though, from the remark בְּסֻדֵּיהָ, *in the city* (v. 7), it would seem that the writer did not live in Jerusalem itself but in the neighbourhood.

From the records we possess of the discussions on the Hebrew canon we see that at the synod at Jerusalem, circa 65 A.D., and at a subsequent synod in Yabue, circa 90 A.D., the question was still an open one whether Ecclesiastes was canonical. The school of Shammai then decided against its canonicity, whilst the school of Hillel passed it as canonical (*Mishna Yadaim*, iii. 5, iv. 6; *Eduyoth*, v. 3). The reasons assigned for its rejection, as given in the Talmud, are that chap. ii. 2, vii. 3, and viii. 5 contradict each other, and that the book does not exhibit any signs of its being inspired (*Sabbath* 30 b, *Megilla* 7 a). According to the *Midrash Rabba* on Eccl. xi. 9, the advice to enjoy sensual pleasures was considered as contradicting the law of Moses (comp. Eccl. xi. 9 with Num. xv. 39) and inclining to heresy. The admonition, however, to fear God and the doctrine of a future judgment were urged in its favour and ultimately prevailed. The sages showed that the contradictions were apparent only, and the book was declared canonical (*Aboth d' R. Nathan*, cap. i). Hence it passed over into the Christian church as a part of the canon.

Literature—The most important commentaries on Ecclesiastes which furnish the best materials for forming an independent opinion on this avowedly difficult book are—Knobel, *Commentar über das Buch Koheleth*, Leipzig, 1836; Ewald, *Qohélet*, in *Die Dichter des Alten Bundes*, 2d ed. vol. ii. 267, &c., Göttingen, 1867; Hitzig, *Der Prediger Salomo im Kurzgefassten exegetischen Handbuch zum alten Testament*, vol. vii., Leipzig, 1877; Stuart, *A Commentary on Ecclesiastes*, New York, 1851; Elster, *Commentar über den Prediger*, Göttingen, 1855; Graetz, *Kohélet*, Leipzig, 1871; Delitzsch, *Hohes Lied und Koheleth*, Leipzig, 1875. The last two give complete vocabularies of the post-Babylonian diction of the book. For the history of the interpretation see Ginsburg, *Coheleth*, commonly called *the Book of Ecclesiastes*, London, 1861. (C. D. G.)

ECCLESIASTICAL COMMISSION. This is a standing commission invested with very important powers, under the operation of which extensive changes have been made in the distribution of the revenues of the Church of England. It was one of the results of the vigorous movements for the reform of public institutions which followed the Reform Act of 1832. In 1835 two commissions were appointed "to consider the state of the several dioceses of England and Wales, with reference to the amount of their revenues and the more equal distribution of episcopal duties, and the prevention of the necessity of attaching by commendam to bishoprics certain benefices with cure of souls; and to consider also the state of the several cathedral and collegiate churches in England and Wales, with a view to the suggestion of such measures as might render them conducive to the efficiency of the established church, and to provide for the best mode of providing for the cure of souls, with special reference to the residence of the clergy on their respective benefices." And it was enacted by 5 and 6 Will. IV. c. 30 that during the existence of the commission the profits of dignities and benefices without cure of souls becoming vacant should be paid over to the treasurer of Queen Anne's Bounty. In consequence of the recommendation of these commissioners, a permanent commission was appointed by 6 and 7 Will. IV. c. 77, for the purpose of preparing and laying before the king in council such schemes as should appear to them to be best adapted for carrying into effect the alterations suggested in the report of the original commission and recited in the Act. The new commission was constituted a corporation with power to purchase and hold lands for the purposes of the Act, notwithstanding the statutes of mortmain. The first members of the commission were the two archbishops and three bishops, the lord chancellor and the principal officers of state, and three laymen named in the Act. By a later Act (3 and 4 Viet. c. 113) all the bishops, the chiefs of the three courts at Westminster, the master of the Rolls, and the judges of the Prerogative Court and Court of Admiralty, and the deans of Canterbury, St Paul's, and Westminster were added to the commission; and power was given to the crown to appoint four, and the archbishop of Canterbury to appoint two additional lay commissioners. The lay commissioners are required to be "members of the United Church of England and Ireland, and to subscribe a declaration to that effect." Five are a quorum; but two bishops at least must be present at any proceeding under the common seal of the commission, and if only two are present they can demand its postponement to a subsequent meeting. Paid commissioners, under the title of church estates commissioners, are also appointed—two by the crown and one by the archbishop of Canterbury. These three are the joint treasurers of the commission, and constitute, along with two members appointed by the commission, the church estates committee, charged with all business relating to the sale, purchase, exchange, letting, or management of any lands, tithes, or hereditaments. The commission has power to make inquiries and examine witnesses on oath. The schemes of the commission having, after due notice to persons affected thereby, been laid before the Queen in Council, may be ratified by orders, specifying the times when they shall take effect, and such orders when published in the *London Gazette* have the same force and effect as Acts of Parliament.

The recommendations of the commission recited in 6 and 7 Will. IV. c. 97 are too numerous to be given here. They include an extensive re-arrangement of the dioceses, equalization of episcopal income, providing residences, &c. By 3 and 4 Viet. c. 113 the fourth report of the original commissioners, dealing chiefly with cathedral and collegiate churches, was carried into effect, a large number of canonries being suspended, and sinecure benefices and dignities suppressed.

The emoluments of these suppressed or suspended offices, and the surplus income of the episcopal sees, constitute the fund at the disposal of the commissioners. By 23 and 24 Viet. c. 124, on the avoidance of any bishopric or archbishopric, all the land and emoluments of these, except the patronage and lands attached to houses of residence, become, by Order in Council, vested in the commissioners, who may, however, reassign to the see so much of the land as may be sufficient to secure the net annual income named for it by statute or order. All the profits and emoluments of the suspended canonries, &c., pass over to the commissioners, as well as the separate estates of those deaneries and canonries which are not suspended. Out of this fund the expenses of the commission are to be paid, and the residue is to be devoted to increasing the efficiency of the church by the augmentation of the smaller bishoprics and of poor livings, the endowment of new churches, and employment of additional ministers.

The substitution of one central corporation for the many local and independent corporations of the church, so far at least as the management of property is concerned, was a constitutional change of great importance, and the effect of it has undoubtedly been to correct the anomalous distribution of ecclesiastical revenues by equalizing incomes and abolishing sinecures. At the same time it is regarded as having made a serious breach in the legal theory of ecclesiastical property. "The important principle," says Cripps, "on which the inviolability of the church establishment depends, that the church generally possesses no property as a corporation, or which is applicable to general purposes, but that such particular ecclesiastical corporation, whether aggregate or sole, has its property separate, distinct, and alienable, according to the intention of the original endowment, was given up without an effort to defend it" (*Laws Relating to the Church and Clergy*, p. 46).

ECCLESIASTICAL LAW generally means the law of the church, in countries where an established religion is recognized by the state, but in a more general sense it would include the whole body of the law relating to religion. It is in this sense that the phrase is used by American lawyers, and it is only in this sense that it can be used of Ireland since the disestablishment of the state church in that country. The relation of the ecclesiastical law to the rest of the law, especially in respect of legislation and judicature, is one of the most important points in the constitution of a country. Where the Roman Catholic religion is recognized by the state the jurisprudence of the canon law prevails, but the relations between the Papal See and the state are governed by special conventions, or concordats. See **CANON LAW**.

The ecclesiastical law of England is remarkable for its complete dependence upon the authority of the state. The Church of England cannot be said to have a corporate existence nor even a representative assembly. The Convocation of York and the Convocation of Canterbury are provincial assemblies possessing no legislative or judicial authority. The ecclesiastical judicatures are for the most part officered by laymen, and the highest court of appeal is the Judicial Committee of the Privy Council. In like manner changes in the ecclesiastical law are made directly by Parliament in the ordinary course of legislation, and in point of fact a very large portion of the existing ecclesiastical law consists of Acts of Parliament.

The sources of the ecclesiastical law of England are thus described by the leading text-writer on this subject:¹—"The ecclesiastical law of England is compounded of these four main ingredients—the civil law, the canon law, the common law, and the statute law. And from these, digested in their proper rank and subordination, to draw out one uniform law of the church is the purport of this book. When these laws do interfere and cross each other, the order of preference is this:—'The civil law submitteth to the canon law; both of these to the common law; and all three to the statute law. So that from any one or more of these, without all of them together, or from all of them together without attending to their comparative obligation, it is not possible to exhibit any distinct prospect of the English ecclesiastical constitution.' Under the head of

¹ *The Ecclesiastical Law*, by Richard Burn, LL.D.

statute law Burn includes 'the Thirty-nine Articles of Religion, agreed upon in Convocation in the year 1562; and in like manner the Rubric of the Book of Common Prayer, which, being both of them established by Acts of Parliament, are to be esteemed as part of the statute law.'

The first principle of the ecclesiastical law is the assertion of the supremacy of the crown, which in the present state of the constitution means the same thing as the supremacy of Parliament. This principle has been maintained ever since the Reformation. Before the Reformation the ecclesiastical supremacy of the Pope was recognized, with certain limitations, in England, and the church itself had some pretensions to ecclesiastical freedom. The freedom of the church is, in fact, one of the standing provisions of those charters on which the English constitution was based. The first provision of Magna Charta is *quod ecclesia Anglicana libera sit*. By the various enactments of the period of the Reformation the whole constitutional position of the church, not merely with reference to the Pope but with reference to the state, was definitely fixed. The legislative power of Convocation was held to extend to the clergy only, and even to that extent required the sanction and assent of the Crown. The common law courts controlled the jurisdiction of the ecclesiastical courts, claiming to have "the exposition of such statutes or Acts of Parliament as concern either the extent of the jurisdiction of these courts or the matters depending before them. And therefore if these courts either refuse to allow these Acts of Parliament, or expound them in any other sense than is truly and properly the exposition of them, the king's great courts of common law may prohibit and control them."

The design of constructing a code of ecclesiastical laws was entertained during the period of the Reformation, but never carried into effect. It is alluded to in various statutes of the reign of Henry VIII., who obtained power to appoint a commission to examine the old ecclesiastical laws, with a view of deciding which ought to be kept and which ought to be abolished; and in the meantime it was enacted that "such canons, institutions, ordinances, synodal or provincial or other ecclesiastical laws or jurisdictions spiritual as be yet accustomed and used here in the Church of England, which necessarily and conveniently are requisite to be put in ure and execution for the time, not being repugnant, contrariant, or derogatory to the laws or statutes of the realm, nor to the prerogatives of the royal crown of the same, or any of them, shall be occupied, exercised, and put in ure for the time within this realm" (35 Henry VIII. c. 16, 25 c. 19, 27 c. 8).

The work was actually undertaken and finished in the reign of Edward VI. by a sub-committee of eight persons, under the name of the *Reformatio Legum Ecclesiasticarum*, which, however, never obtained the royal assent. Although the powers of the 25 Henry VIII. c. 1, were revived by the 1 Elizabeth c. 1, the scheme was never executed, and the ecclesiastical laws remained on the footing assigned to them in that statute,—so much of the old ecclesiastical laws might be used as had been actually in use and was not repugnant to the laws of the realm.

The statement is, indeed, made by Sir R. Phillimore that the "Church of England has at all times, before and since the Reformation, claimed the right of an independent church in an independent kingdom, to be governed by the laws which she has deemed it expedient to adopt." This position can only be accepted if it is confined, as the authorities cited for it are confined, to the resistance of interference from abroad. If it mean that the church, as distinguished from the kingdom, has claimed to be governed by laws of her own making, all that can be said is that the claim has been singularly unsuccessful. From the time of the Reformation no change has been made in the law of

the church which has not been made by the king and parliament, sometimes indirectly, as by confirming the resolutions of Convocation, but for the most part by statute. The list of statutes cited in Sir R. Phillimore's *Ecclesiastical Law* fills eleven pages. It is only by a kind of legal fiction that the church can be said to have deemed it expedient to adopt these laws.

The terms on which the Church Establishment of Ireland was abolished by 32 and 33 Vict. c. 42 may be mentioned. By sect. 20 the present ecclesiastical law is made binding on the members for the time being of the church, "as if they had mutually contracted and agreed to abide by and observe the same," and by section 21 it is enacted that the ecclesiastical courts shall cease after 1st January 1871, and that the ecclesiastical laws of Ireland, except so far as relates to matrimonial causes and matters, shall cease to exist as law. (E. R.)

ECCLESIASTICUS. See APOCRYPHA.

ECHIDNA, or PORCUPINE ANT-EATER (*Echidna hystrix*), one of the four known species of Monotremata, the lowest order of Mammalia. It is a native of Australia, where it chiefly abounds in New South Wales, inhabiting rocky and mountainous districts, where it burrows among the loose sand, or hides itself in crevices of rocks. In size and appearance it bears a considerable resemblance to the hedgehog, its upper surface being covered over with strong spines directed backwards, and on the back inwards so as to cross each other on the middle line. The spines in the neighbourhood of the tail form a tuft sufficient to hide that almost rudimentary organ. The head is produced into a long tubular snout, covered with skin for the greater part of its length. The opening of the mouth is small, and from it the echidna puts forth its long slender tongue, lubricated with a viscid secretion, by means of which it seizes the ants and other insects on which it feeds. It is entirely destitute of teeth. Its legs are short and strong, and form, with its broad feet and large solid nails, powerful burrowing organs. In common with the other monotremes, the male echidna has its heel provided with a sharp hollow spur, connected with a secreting gland, and with muscles capable of pressing the secretion from the gland into the spur; but as the animal has never been observed to use this in defending itself, the spur probably serves some other purpose than that of offence or defence. It is a nocturnal or crepuscular animal, generally sleeping during the day, but showing considerable activity by night. When attacked it seeks to escape either by rolling itself into a ball, its erect spines proving a formidable barrier to its capture, or by burrowing into the sand, which its powerful limbs enable it to do with great celerity. "The only mode of carrying the creature," says Bennet (*Gatherings of a Naturalist in Australasia*) "is by one of the hind legs, when it may be removed to any place with great facility, for an attempt to seize it by any other part of the body, from its powerful resistance and the sharpness of the spines, will soon oblige the captor to relinquish his hold." They are exceedingly restless in confinement, and constantly endeavour by burrowing to effect their escape. From the quantity of sand and mud always found in the alimentary canal of the echidna, it is supposed that these ingredients must be necessary to the proper digestion of its insect food. The only other members of this family are the Short-spined Echidna (*Echidna setosa*), confined to Tasmania, and differing from the former species chiefly in the shortness of its spines, which are nearly hidden by the long harsh fur, and the Echidna Bruynii—a new species discovered in 1877 in the mountains on the north-east coast of New Guinea, at an elevation of 3500 feet. By many naturalists the generic term *Echidna* has lately been abandoned in favour of *Tachyglossus* of Illiger.

ECHINODERMATA (from *ἐχῆρος*, a hedgehog or sea-urchin, and *δέρμα*, skin), a class of marine animals which constitutes with the class *Scolecida* the sub-kingdom *Amuloida* of Huxley, or, according to some authorities, is a distinct sub-kingdom of the Invertebrata. Familiar examples of the Echinodermata are the Sea-urchins, Star-fishes, Feather-stars, and Sea cucumbers of the coasts of Britain. The characteristics of the group may be briefly summarized thus. The adult presents a more or less marked, although never perfect, radial symmetry of parts; the larva, in most instances, is bilaterally symmetrical. The perisome or dermis develops a calcareous skeleton of numerous interlocking plates or of detached plates or spicules. The mesenlar tissue consists chiefly of unstriped fibres. The intestinal canal terminates in a distinct anal aperture. An aquiferous or ambulacral system of organs, regarded as homologous with the water-vascular system of the *Scolecida*, is generally present; and there is a nervous system consisting of a ganglionated circular or polygonal cord, which surrounds the œsophagus, and sends off branches parallel with and superficial to the ambulacral canals. The sexes are in the majority of cases distinct, and the reproductive organs are generally placed symmetrically with respect to the radially disposed skeleton.

In all Echinodermata of which the life-history has been worked out, the larva, *echinopodium*, or, as it has been termed by Sir Wyville Thomson, the *pseud-embryo*, produced from the egg is, with but one or two exceptions, ovoid, free swimming, and provided with cilia, which become after a time confined to one or more bilaterally symmetrical bands running transversely or obliquely to the long axis of the body, and frequently borne on processes of the same. In the Asteridea and Holothuridea the larva is vermiform and devoid of skeleton; in the Echinidea, it is plateform (Latin, *plateus*, a pent-house, or breast-work), and has a continuous calcareous skeleton, passing into and affording support to the body processes. A stomach, with an œsophagus and intestine, which make with each other an angle open towards the ventral side of the body, is early developed in the Echinoderm larva. The peritoneal cavity and ambulacral system of vessels are developed from diverticula of the alimentary canal. A tube formed by an involution of the integument of the pseud-embryo to one side of the dorsal line may remain connected with the ambulacral system of the adult as the madreporic canal. In the Echinidea, Asteridea, Ophiuridea, and Crinoidea the body-wall of the adult is formed from the blastema; the larval body, more or less of the intestine, and, when present, the skeleton are cast off or absorbed into the new organism, and another mouth appears in the centre of the circular vessel. It is by this peculiar metagenetic mode of development of the Echinoderm within its larva that the class Echinodermata is specially allied to the orders *Turbellaria* and *Teniaria* of the class *Scolecida*.

The Echinodermata may be divided into the following orders:—(I.) *Echinidea*, or Sea-urchins; (II.) *Asteridea*, or Star-fishes; (III.) *Ophiuridea*, or Sand-stars; (IV.) *Crinoidea*, or Feather-stars; (V.) *Cystidea*; (VI.) *Echinoasteridea*; (VII.) *Blastoidea*; (VIII.) *Holothuridea*, or Sea-slugs. Of these orders V., VI., and VII. have been extinct since the Palæozoic period. By some authorities the Edrioasteroidea are included with the Cystidea.

Order I.—ECHINIDEA.—The body in the Echinidea is spheroidal, oval, discoid, or heart-shaped, and the shell, test, or perisome bears numerous spines. A common European type of the group is the species *Psammechinus* (*Echinus*, L.) *esculentus* (see fig. 1). In certain forms (*Scutellidae*) the test is perforated by slit-like apertures, and enormously lobed or digitate (fig. 2). With few exceptions the test is a rigid

structure of numerous plates united by their edges. In the *Echinothuridae*, however (*Calveria*, *Phormosoma*, and the ex-

FIG. 1.—*Psammechinus esculentus*.

tinued *Echinothuria* and *Lepidocentrus*), and also in the Palæozoic genera *Archæocidaris*, *Lepidesthes*, and *Lepidocchinus*, the plates of the corona overlap, so as to resemble the peristomial plates of *Cidaris*.

The plates are composed of a dense calcareous network, consisting chiefly of calcium carbonate. As the test is invested with an epidermis, and is produced mainly by calcification of the mesoderm, it is to be regarded as an internal shell or endo-skeleton.

In the typical recent echini the walls of the corona or main body of the shell, when freed from spines, are seen to consist of five zones or areas, the *ambulacra* (Latin, *ambulacrum*, a walk), composed of double rows of pentagonal plates, and alternating with five other double rows, the *interambulacra*. In the Palæozoic forms, which constitute the sub-order *Perischoechinidae* of McCoy, the interambulacrum is made up

FIG. 2.—*Rotula augusti*.

of more than two rows of plates, of which the intermediate and central are hexagonal in form (see figs. 3 and 4). In the

FIG. 3.—*Echinus gracilis*.

FIG. 4.—*Stenoclinus intermedius*.

a, portion of ambulacral area; b, poriferous zone; c, two interambulacral plates; d, primary tubercles. (After Wright.)

genera *Melonites* and *Oligoporus* there are extra ambulacral as well as interambulacral plates. The ambulacra, which

are usually narrower than the interambulacra, have near their outer edge small shield-like spaces, *umbones*, bounded by a more or less elevated wall, and perforated by pairs of small orifices or pores for the protrusion of the feet or *pedicels*, each pair of pores corresponding to one of the pore plates—the primitive ossicles which commonly unite to form the ambulacral plates. The ambulacra are either homogeneous, i.e., composed of similar elements gradually diminishing in size towards the poles of the test, or (as in the *Spatangoida* and most of the *Clypeastroidea*) are heterogeneous, having the upper portion petaloid in shape, and the lower with pores scattered in areas not always confined to the ambulacral plates, or arranged in ramifying fasciae. In the *Spatangoida* the anterior unpaired ambulacrum is commonly obsolete (see fig. 5). In the Oolitic genus

Fig 5.—*Spatangus purpureus*

Dysaster, the two postero-lateral ambulacra, forming the *bivium*, are separate from the rest, and converge over the anal opening; while the three anterior, the *trivium*, unite at the apical disk (see fig. 8). The growth of the urchin in length is effected by the formation of new plates at the apical end of the corona, and in breadth by additions to the margins of the plates. On the surface of the plates are tubercles of different sizes, each with a knob or elevation, sometimes crenulated, by which the aratabulum of the spine is attached (see figs 4 and 5). The presence or absence in the tubercle of a central perforation for the passage of a ligament for the spine is an important distinguishing character in various groups of fossil echini. The spines in the young state are ciliated, like the plates of the test they are composed of a calcareous network, and are interpenetrated and covered by the perisome, which contains the muscular fibres by which they are moved. They are short in the *Clypeastroidea* and *Spatangoida*, and of various lengths in the *Echinoida*, and offer a considerable diversity of form and ornamentation. Dr Gray (*Ann. of Nat Hist*, 1. p. 414) mentions the discovery in Sicily of the fragment of a spine of an echinus, the circumference of which was nearly 1½ inches, and the length more than 8 inches. In *Porocidaris purpurata*, a deep-sea form, the spines are paddle-shaped, and very flat, and are serrate on the edges, in *Cleophrurus* the long curved spines resemble the antennae of certain beetles. Scattered over the surface of the test, and more especially on the oral membrane, are the *pedicellariæ*, generally regarded as peculiarly modified spines, these, when well developed (fig 6), consist of a long flexible stem, fur-

Fig 6.—*Pedicellariæ* of *Echinus saxatilis* a, open, b closed. (After Gegenbaur)

nished at the summit with a forceps of three pincers or prongs, which snap together, and seize firm hold of any object that comes in their way. They serve for the removal from the neighbourhood of the shell of dirt of all kinds, and apparently also for defence. *Calveria fenestrata* has *pedicellariæ* with four valves. In some *Spatangoid* genera the corona bears symmetrical bands of minute tubercles with attached spines, the *semitæ* or *fascioles*, distinguished, according to their position with respect to the anus or to the apical or the marginal terminations of the petaloid ambulacra, as *sub-anal*, *circum-anal*, *intrapetalous*, and *peripetalous*. The spines of the *semitæ* have a thick integumentary covering, and except at the enlarged apex, are closely studded with cilia. Lovén has shown the occurrence, in all Echinidea but *Cidaris*, of another kind of appendages of the test, possibly sensory organs, to which he has given the name of *sphæridia*. These are button-like, spheroidal bodies, seldom above 1/100th inch in length, furnished with a short stalk, and normally articulated with small projecting tubercles on the plates of the ambulacra and peristome. Sometimes they become concealed by a layer of the test, in which there remains only a fine external fissure. At the summit or apical pole of the test is a space occupied by the ocular and genital plates, which in the *Echinoida* (*Endocyclica*) encircle the anus with its anal plates. The five genital plates, which are opposite the interambulacra, or interradian in position, are perforated by apertures for the exit of the reproductive products. In the *Clypeastroidea* and *Spatangoida* (*Exocyclica*), in which the anus is eccentric, and exterior to the apical disk, one of the genital plates is usually imperforate (fig 7). The five ocular plates are situated radially, crowning the apical ends of the ambulacra; on the surface of each is a depression, having a pore for an ocellus or eye-spot. Always, except in the *Clypeastroidea*, the right antero lateral genital plate, or, in other words, that situated to the right of the anterior ambulacrum of the trivium, is larger than the others, and bears the convex, perforated *madreporic tubercle* or *madreporite*. In the *Clypeastroidea* this is most frequently extended over the other apical plates. The hinder genital plate, with apparently one exception, is wanting in the *Spatangoida*, its place being occupied by the madreporite. The Palæozoic Echinidea differ from the more modern forms by the greater number of perforations of their ocular and genital plates. At the base of the test is the mouth with its buccal membrane and plates. The species *Leskia mirabilis* (the type of the sub-family *Leskiadae*, family *Spatangidae*) has both mouth and anus closed by converging triangular valves. In the *Echinoida* and *Clypeastroidea* the mouth is central in position, and provided with teeth; in the *Spatangoida* it is eccentric and edentulous. The teeth resemble those of Rodents in form, and are arranged in hard wedge-shaped sockets or *alveoli*, which by their union form a pentagonal cone. As the outer substance of the tooth is harder than the inner, it is less readily worn away, and thus always presents a sharp edge. Each alveolus is composed of two halves united in the middle line, and each half, again, consists of a superior and inferior portion. The alveoli are inter-radial in position, or opposite the interambulacra. They are connected by transverse muscular fibres, and alternate with superiorly placed, thickish, radial structures, the *rotulæ* or *falces*, which, in the *Echinoida*, bear each a bifurcated piece, the *radius*. This skeletal mouth-apparatus is commonly known as

Fig 7.—*Echinocyamus pusillus*
Upper surface (a), showing four genital pores and lower surface (b), with anus half-way between mouth and posterior border

"Aristotle's lantern." The calcified internal arched processes termed *auriculæ*, at the oral end of the ambulacra in the *Echinoida* (of the interambulacra in *Cidaridæ*), regarded as homologous with the internal ambulacral ossicles of the Asteridea and Ophiuridea, are formed each of two pieces. From the top of the auriculæ pass retractor muscles to the outer edge of the alveoli. The oral skeleton is provided also with protractors proceeding from the alveoli to the lower interambulacral edge of the corona, besides special muscles connected with the radii. In the *Clypeastroida* arched (in *Cidaridæ* unarched) processes are given off from the ambulacral plates, at the sides of the ambulacral canals; and in the Clypeastroid genus *Scutella* the dorsal and ventral walls of the corona are connected by vertical calcareous plates or trabeculae. None of the above-mentioned internal calcareous processes is developed in the *Spatangoida*. The mouth communicates by a tortuous œsophagus with the stomach. The intestine forms a sort of festoon on the inner side of the shell, and is attached to it by a mesentery.

Of the internal organs of the Echinidea the most important and characteristic are those constituting the ambulacral system. These are (1) a circular or slightly pentagonal vessel placed around and traversed by the œsophagus, on the inside of the alveoli, and between the nervous and blood-vascular rings; (2) œcal appendages of this vessel, called Polian vesicles (absent in the *Clypeastroida* and *Spatangoida*), answering to the racemose appendages of the Holothuridea; (3) the membranous or calcareous madreporic canal, termed also the sand-canal, which runs nearly vertically through the axis of the body, and, communicating with the exterior by the madreporic tubercle, supplies water to 1; (4) vessels radiating from 1 along the parietes of the body, and opening eventually into basal sacs, or *ampullæ*, proceeding from the canals of the pedicels shortly above their origin. In the vessels of the ambulacral system is contained a watery fluid strained from the perivisceral cavity. The pedicels, which may vary considerably in shape, are tubular structures, usually terminated by a sucking-disk; they have contractile, muscular walls, and are capable of being protruded beyond the extremities of the spines. They subserve locomotor, tactile, or branchial functions. The corpusculated perivisceral fluid is kept in motion by the cilia clothing the lining membrane of the body and the viscera. Where modified pedicels or ambulacral gills are absent, as in the *Echinoida*, the *Cidaridæ* excepted, aeration of that fluid is apparently promoted by branchial developments from the peristome, the hollow stems of which communicate with the body-cavity. The nervous system consists of a slender, pentagonal, red or violet hoop around the gullet, superficial to the circular ambulacral vessel, with five ganglia sending off as many cords, which, passing out between the alveoli, take a course similar to that of the ambulacral radial equals, giving off fine side branches which pass in their course through the ambulacral pores, probably supplying the pedicels, spines, and pedicellariæ, and terminate eventually in the pigmented eye-spots. The principal vessels of the pseud-hæmal or blood-vascular system of the Echinidea appear to be two trunks, the one on the dorsal, the other on the ventral side of the alimentary canal, these, according to Hoffmann, communicate either directly or by a distinct trunk with the water-vascular ring.

From an examination of *Echinus sphaera*, *Psammecchinus miliaris*, *Toxopneustes lividus*, and *Amphidictus cordatus*, Perrier determined that, as maintained by Hoffmann, the circulatory and aquiferous systems are identical, that the so called "heart" is only a gland, which opens by a canal into a funnel-shaped space bounded by the lining membrane of the test and the madreporite; that the artery proceeding from the water-vascular ring is distributed upon the first loop of the intestine, forming there ramifications which

unite with those of the intestinal vein; and that the vein has no communication with the water-vascular ring, but is connected by ten branches and by its two extremities with a collateral canal, which floats freely in the perivisceral cavity beneath the intestine. Further, he found that the ambulacral vessels and their branches terminate blindly, the circulation consisting simply in a to-and-fro movement of their contents.

The reproductive organs are large racemose glands, situated beneath the upper termination of the interambulacra, and opening externally by the genital pores. The sexes are distinct. The spermatozoa have vibratile filaments; the egg is fecundated after leaving the body of the female, and in about eight hours undergoes complete yolk-division.

The pseud-embryo or echinopædium, at first eiliated and spheroidal, becomes after a time wedge-shaped, at its broad end appears the mouth or *pseudostome*, and at the other the anus or *pseudoproct*. Simultaneously with these the skeletal rods and eiliated bands of the pluteus begin to be produced. The development of the ambulacral system commences with the formation of a sac which lies to the left of the junction of the pseud-embryonic gullet and stomach, and is prolonged into a canal opening by a pore on the dorsal surface of the larva. The blind end of the sac becomes a quinque-petaloid rosette, from which radiate the ambulacral vessels, a new mouth is formed in the centre of this, at the bottom of a depression in the integument of the pseud-embryo, and the canal of the sac becomes the madreporic tube. The skeleton of the pluteus separates, as development proceeds, into several pieces, and is by degrees discarded, whilst its processes atrophy, and the body assumes the rounded form of the embryo urchin. This, however, has in many cases to undergo sundry important changes before its resemblance to the adult is complete. Thus in the young of species of *Spatangus* the peristome is almost central, and is pentagonal in form. In the *Echinoida*, before the appearance of the anus in the embryo, its place is occupied by a single plate, the *sub-anal*, and the anus appears near its border, towards the posterior right ambulacrum. It lies within a circle formed by five imperforate pieces, the future genital plates, and these again are surrounded by five imperforate ocular plates, with intervening ambulacral plates. The central anal plate persists in the family *Salenidæ* among the *Echinoida*. If it be considered as homologous with the dorsal central plate of *Marsipites*, or the basalia of the calyx in other Crinoids, the genital plates correspond to the parabasal, and the ocular to the first radialia.

The food of the Echinidea consists either of seaweed, and small shell-fish and crustaceans, which are conveyed to the mouth by the pedicels, or, as in the case of the edentulous forms, of sand and earth containing nutritive material. In the species *Anochanus emensis*, one of the *Cassidulidæ*, Grube discovered the presence of an incubatory chamber at the apical pole of the test, containing embryos in various stages of their growth. Certain species, as observed by Carl-haud, Deshayes, and Lory, have the power at a very early age of drilling for themselves burrows in the hardest rocks, such as granite and gneiss.

Allusion is made to the echinus in the writings of Aristophanes, Horace, Martial, and other classical authors. By the ancients it was considered a delicacy, and the common species *Psammecchinus* (*Echinus*, L.) *esculentus*, Ag., especially in spring, when the ova are matured, is still eaten in some parts of Europe. Sir Thomas Browne, in his *Vulgar Errors*, mentions a notion formerly current that the spines of the echinus were a remedy for the stone, and "films in horses' eyes." They are put to practical use in some countries as slate-pencils.

Various systems of classification have been adopted for the Echinidea. In the following scheme the principal groups are arranged chiefly according to the position of the anal opening and the nature of the ambulacra.

Sub-order I.—TESSELATA. Echinidea with interambulacra of more than two rows of plates.

Sub-order II.—TYPICA. Echinidea with interambulacra of but two rows of plates.

Group I.—REGULARIA or ENDOCYCLICA. Mouth central or sub-central, anus usually central and opposite the mouth, and never exterior to apical disk.

A. Anus central

1. Shell round

Cidaridæ. Tubercles smooth, perforate, peristome unnotched, anal plates ten, auriculæ inclosed; buccal branchiæ absent.

Dialematidæ. Tubercles cretulate, perforate, peristome notched, spines hollow. Allied forms are the fossil *Hemidaridæ*.

Arbaciadae. Tubercles smooth, imperforate, four large anal plates, auriculæ closed

Echinidae. Tubercles imperforate, or perforate and crenulate, anal plates numerous; pairs of pores in ranks of three, four, or more.

ii. Shell oval or elliptical.

Echinometridae. Pores in ranks of five or six pairs

B. Anus eccentric through intervention of one or several supernumerary apical plates

Saleniadae. All fossil forms, with exception of *Salenia rarispinna*

Group II.—IRREGULARIA or EXOCYCLICA. Anus eccentric, not within the apical disk.

A. Ambulacra simple, not petaloid

Galeritidae. Mouth central, shell globular or sub-pentagonal; a single apex at which the ambulacra converge.

Dysasteridae. Mouth eccentric, shell ovoid or heart-shaped, two apices, at which the bivium and trivium respectively converge

B. Ambulacra more or less petaloid

i. Dental apparatus present

Clypeastridae. Shell more or less flattened, sub-pentagonal

Scutellidae. Shell depressed, discoidal, often digitate or perforated, lower surface with ramifying grooves

ii. Dental apparatus absent

Cassidulidae. Mouth central or nearly so; peristome sub-pentagonal.

Spatangidae. Mouth eccentric, transverse or reniform.

To the group Regularia must be added the Cretaceous and Recent family of *Echinothuridae*. The Echinidea are represented in Palaeo-

(2 in fig 8), *Melonites*, *Oligoporus*, and *Lepidesthes* (see *Quart. Jour. Geol. Soc.*, xxx 307). The *Echinidea* and *Dysasteridae* occur first in the Trias, and are represented by numerous species in Mesozoic strata; the *Saleniadae*, *Galeritidae*, and *Cassidulidae* make their earliest appearance in rocks of Jurassic, and the *Spatangidae*, including the sub-family *Ananchytidae*, in rocks of Cretaceous age. The accompanying figures represent fossil forms of Echinidea characteristic of various strata. Some account of the distribution in space of the Echinidea, together with that of other classes of the Echinodermata, will be found at page 278 of the present volume. See also Sir Wyville Thomson, *Proc. Roy. Soc.*, xx. 1872.

Order II.—ASTERIDEA.—The Asteridea, or Star-fishes, have mostly a star-shaped body, composed of a central disk and five or more rays. The common British species of *Solaster*, *S. papposus* (fig. 10), has ordinarily 13 rays;

FIG 10.—*Solaster papposus* (upper surface).

S. helianthoides, a South American species, has as many as 34, the extinct *S. Moretoni* of the Great Oolite had 33, and another fossil species, of Devonian age, *Helianthaster Rhenanus*, had 16 rays. The rays are sometimes very short (fig 11), or altogether wanting, the body having

FIG 11.—*Astrogonium phrygianum* (upper surface)

the form of a pentagonal disk. In the *Brisingidae* they may attain a length of many feet. The peristome in the *Asteridea* is coriaceous, and consists of an ectoderm with a thin chitinated cuticle, a muscular mesoderm which contains calcareous skeletal plates or ossicula, and an

zoic strata by the Tesselata or Perischoechinidae, *Palaechinus* (see 1 in fig 8), *Perischodonus*, *Lepidochinus*, *Eocidaris*, *Archaeocidaris*

internal ciliated epithelium. Studding the perisome are numerous spines, attached to the ossicula on the dorsal surface and to those bordering the ambulacral grooves; sometimes also there are tufts of bristles, the *parillae*. The pedicellariae are attached to the perisome and spines, and are either sessile or provided with short foot-stalks. Except in one group, they have two blades only, which are moved by divaricator and adductor muscles.

The lower or oral surface of the star-fish with the ambulacra corresponds to the ambulacral, the aboral or antambulacral surface to the ambulacral, the aboral or antambulacral surface to the interambulacral areas of the echinus. The deep ambulacral grooves which occupy the middle of the lower face of each ray are formed each by a series of plates, the *vertebral ossicles*, articulated to one another by their inner opposed ends, and united by their lower or outer ends to

FIG. 12.—Section of ray of *Astropecten aurantiacus*.

a, vertebral ossicles; b, adambulacral ossicles; c, d, marginal ossicles; e, parillae. (After Gaudry.)

rows of plates, the *adambulacral ossicles*, which form the margins of the grooves, and are themselves succeeded by one or more series of *marginal ossicles* (fig. 12). The outer ends of the innermost pairs of ambulacral ossicles unite round the mouth to form five crests, which bear spines and pedicellariae. On the aboral surface of the body are the *tergal plates* (fig. 13). Transverse muscular fibres unite the lateral halves of the arm-segments; similar fibres supply the floor of the ambulacral groove; besides these there are intervertebral and interambulacral longitudinal muscles. The ambulacral grooves are nearly filled with the tube-feet or pedicels, which have a nervous external and muscular internal layer, are usually cylindrical in form and furnished with terminal sucking-disks, and communicate by ducts passing through the ambulacral pores with vesicles lying above the ambulacral ossicles and opening into the ambulacral canal of the ray. In the common star-fish, *Asterias (Asteracanthion) rubens* the pores form a zig-zag line on each side of the ambulacral groove, and the pedicels passing through them thus come to be four-ranked (fig. 14). They are formed by notches or semi-

FIG. 13.—Tergal skeleton of *Asterias rubens*.

pores incised one on the distal and the other on the oral

surface of each ambulacral ossicle, and lying alternately external and internal to one another in position on successive ossicles (fig. 15). The mouth, which is devoid of dentary apparatus, is situated in the middle of a membranous disk in the centre of the oral surface. It leads by a short gullet into the

FIG. 15.—Ossicles of ambulacral groove of *Asterias rubens*, viewed from above a, pore for pedicel

stomach. The stomach in most star-fishes is produced into five sacculated prolongations (*cardiac sacs*); above these it contracts, but again widens to form the *pyloric sac*, this gives rise to five tubes, which open out in each ray into a pair of parallel diverticula having numerous caecal dilatations, and connected by a mesentery with the antambulacral perisome. The pyloric sac in most cases leads into a short intestine terminating in an anus situated in the left posterior interradial space. In *Astropecten*, *Ctenodiscus*, and *Luidia* there is no anus. The madreporic tubercle is situated dorsally in the body disk, near one of the interradial angles; it is oval or slightly pentagonal in form, and the surface is marked with undulating grooves, and is finely perforated (fig. 16). In some genera

FIG. 16.—Antambulacral surface of *Asterias rubens* a, madreporite, a', the same magnified, b, anus

(*Ophidiaster*, *Echinaster*) there are several interradially placed madreporic tubercles. The doubly involuted madreporic canal is invested by the peritoneal membrane, which incloses a sinus, or "heart," as it has been termed, it passes downwards into a pentagonal circum-oral rug which gives off the five radial canals occupying the uppermost part of the ambulacral grooves. The circum-oral ring may or may not possess Polian vesicles. A dorsal or aboral ring has been described as communicating with the "heart," and sending off interradial branches to the genital glands, the products of which, in the case of star-fishes devoid of external genital apertures, it has been supposed they are the means of removing. The genital glands are racemose masses placed interradially in pairs; their processes sometimes extend a considerable distance into the arms. The nervous system consists mainly of a circular canal around the gullet, with five ambulacral trunks opening into it at their inner ends. The ambulacral neural trunk in each ray underlies a strong band of transverse fibres, by which it is separated from the ambulacral canal above. At the extremity of the ray the nerve terminates in an eye and its tentacle. The eyes are small processes of the ectoderm, having a convex surface or cornea containing a large number of simple, conical, pigmented ocelli. In the peritoneal cavity and ambulacral vessels is a watery fluid containing corpuscles. Respiration appears to be effected by means of water supplied

are usually four interradially placed Polian vesicles. The necks of the Polian vesicles and the ambulacral ring give off the diverticula termed by Simrook *vasa ambulacralia* can. From the ambulacral ring proceed the five radial canals between the superambulacral plates and the axial ossicles. In front of each ossicle they give off right and left branches to the pedicels. These are tentacle-like, devoid of basal vesicles, and, except in the *Euryalida*, pass out through openings between the superambulacral and lateral plates. The nervous system consists of an oral ring, which supplies a branch to each arm, running superficial to its radial ambulacral canal. Between the nerve and the latter is a neural canal. The genital organs are pairs of reemose glands attached to the inner dorsal surface of the disk; their products are shed into the perivisceral cavity, whence they make their way through the genital clefts between the origins of the arms.

Hermaphroditism has been observed in the species *Ophiopsis squamata*; and in some genera, as *Ophiocoma* and *Ophiactis*, scissiparous reproduction occurs. According to Lutken, this at an early age is more especially exhibited by the six-rayed forms. In certain cases development takes place within the egg, without any free pseud-embryonic stage; but most generally metamorphosis from a pluteiform larva takes place. The bilaterally symmetrical skeleton of the pluteus consists of eight radially diverging calcareous rods. The development of the embryo commences with the production of two cylindrical solid bodies, one on each side of the gullet, which form cellular blastemic masses, one behind and another in front of the stomach, and a third to the left of the pseudostome. The ambulacral system of the adult is developed from the last of these, which unites with the mass in front of the stomach to form the ventral portion of the body, whilst the posterior mass furnishes the dorsal portion.

The Ophiuridea may be classified as follows.—

Sub-order I.—OPHIURIDE Arms unbranched; ambulacral furrows covered with plates, genital clefts ordinarily five; habit creeping

A. Oral clefts armed

(i.) No papillae angulares.

OPHIODERMATIDÆ Buccal scutes trigonal; disk granulated. Ex. *Ophiura* (*Ophioderma*), *Ophiocenta*, *Ophiopsammus*.

OPHIOLIPIDÆ Buccal scutes pentagonal; disk scales naked. Ex. *Ophiopsis*, *Ophiocrinus*, *Ophiopus*.

AMPHIURIDÆ Disk rugged and scaly; ray-plates spinous. Ex. *Amphiura*, *Ophiacantha*, *Ophiopholis*, *Ophiostigma*, *Ophiactis*.

ORITHMYRIDÆ Disk naked, rays clothed with soft integument. Ex. *Ophiomyra*, *Ophiocolex*.

(ii.) Papillae angulares present.

OPHIOMIDÆ Disk covered with solid plates. Ex. *Ophiocoma*, *Ophiomastix*, *Ophiurium*.

B Oral clefts unarmed

OPHIOTURIDÆ Radial plates very large. Ex. *Ophiotrix*, *Ophiocnemis*, *Ophiogymna*.

Sub-order II.—EURYALIDÆ Arms simple or ramified, and capable of being rolled up towards the mouth; ambulacral furrows covered by soft integument. Spines are not present, but there are tufts of papillae on the ventral surface of the arms; genital clefts ten.

ASTROPHYTIDÆ *Astrophuton*, *Trichaster*, *Asteronys*, *Asteromorpha*, *Asteropora*.

Distribution in time of Ophiuridea.—The following Palaeozoic genera are commonly referred to the Ophiuridea.—*Protaster* (Lower Silurian); *Palaeodiscus*, *Aceroura*, and *Eutradia* (Upper Silurian); *Eugaster* (Devonian of New York). *Ophiura* (?) occurs in the Carboniferous Limestone of Russia. In the Muschelkalk occur *Apodura* and *Aplodoma*, and in higher Secondary strata *Ophioderma*, *Ophiocoma*, *Amphiura*, and other genera.

The Ophiuridea and Asteridea possess, in a marked degree, the power exhibited by the whole of the Echinodermata of reproducing lost portions of the body. The former have received the name of "Brittle-stars" on account of the remarkable facility with which species of the genus *Ophiocoma* not merely cast away their arms entire, but, at will, rapidly break them into little pieces. The same property has been noticed in the genus *Luidia* among the star-fishes, in the Crinoidean genus *Comatula*, and the *Synaptidæ*

among the Holothuridea. Writing of a species of *Luidia*, Prof. E. Forbes remarks: "The first time I ever took one of these creatures I succeeded in getting it into the boat entire. Never having seen one before, and quite unconscious of its suicidal powers, I spread it out on a rowing bench, the better to admire its form and colours. On attempting to remove it for preservation, to my horror and disappointment, I found only an assemblage of rejected members. My conservative endeavours were all neutralized by its destructive exertions, and it is now badly represented in my cabinet by a diskless arm and an armless disk." Major Fred. H. Lang relates (*Nature*, Oct. 12, 1876), that during a dredging expedition in Torbay, presuming on the fact that as a rule he could take up the specimens of *Comatula rosacea* and *Ophiocoma rosula* he had captured without occasioning their dismemberment, he "put about a hundred of the two sorts into a sponge-bag; but this was asking too much of them;" for on reaching home he found "that both Feather-stars and Brittle-stars had converted themselves into a mass of mince-meat! It would have been difficult to find a single portion of an arm a quarter of an inch long."

Order IV.—CRINOIDEA.—The body in the Crinoidea is cup-shaped or bursiform, and its base always in the young state and usually in the adult is attached by the apical pole either directly or, as more commonly, by means of a calcareous stem to submarine objects. The inferior or dorsal wall of the body or calyx is formed of polygonal plates articulated by their edges, and the superior or ventral face or disk, which may be either flat or arched, is formed either by a perisomal membrane, occasionally strengthened with scattered calcifications, or, as in the *Tessellata*, by regularly arranged plates, *tegmina*, resembling those of the inferior wall. At the border of the calyx are 2-18, usually 5, arms or *brachia*, which are movable, and can be closed together over the oral disk (fig. 22). Between them, commonly in the centre of the disk, is the mouth, and near it, in one of the interradial spaces, is the anus.

It has been shown by Sir Wyville Thomson, (*Phil. Trans.* vol. clv pt. 2), that the skeleton of *Antedon rosea* may be divided into two systems of plates the radial and the perisomal, the former including the articuli of the stem, the centro-diskal plate, the radial plate, and the joints of the arms and pinnules, and the latter the basal, oral, and anal plates, and the interradial and other plates or spicules developed in the disk-membrane. The body of

FIG. 21.—*Fentacrinus caput-Medusa*. (After Guttard.)

the pentacrinoid is at first, while yet included within the pseud-embryo, and during its earliest fixed stage, surrounded and inclosed by plates of the perisomic system alone." The predominance of the perisomic system in the calyx of the older Crinoids and forms allied to them is hence a fact of considerable interest to the embryologist.

The stem is made up of numerous ossicles articulated and interpenetrated by elastic fibres and soft connective tissue. It is attached at its distal end by a root-like expansion, or by numerous, filamentous, branched cirri, having joints similar to those of the stem. Other and unbranched cirri are attached in whorls to many of the ossicles of the stem. Through the centre of the stem runs a canal containing a soft solid substance. In the adult *Antedon*, as has been pointed out by Dr Carpenter (*Proc. Roy Soc.*, 1876), the medullary portion of the Crinoidal axis passes up through a pentangular five-chambered dilatation of its cortical portion within the centro-dorsal plate, and, reaching the cavity of the calyx, forms the pedicle by which chiefly the basal or dorsal surface of the visceral mass is attached to the calyx. The pedicle enters into the axial canal and passes through out its entire length, more or less imbedded in its walls, to the commencement of the subtentacular canals, where it apparently becomes continuous with the generative plexus of the disk. The stem varies in length, being short in *Apocrinus*, long in *Pentacrinus*; it is round and sometimes moniliform in most Palæozoic Crinoids, but in *Platycrinus* compressed as it nears the calyx; in *Woolacrinus* it tapers from the calyx downwards. In the Palæozoic Crinoids the articulations of the ossicles radiate from the central canal, which is larger than in the more modern forms. In the Mesozoic genera the articular facets are commonly united by crescentic or stellate ridges. In the Silurian genus *Periechocrinus* the ossicles of the stem are alternately thicker and thinner. The calyx, which may be regarded as formed of the uppermost ossicles of the stem, is composed of several series of plates. The lowest of these is commonly formed by 2-6 pieces, the *basalia*, which in *Rhizocrinus* appear to be represented by a single central plate. The *basalia* in the *Tessellate* are succeeded by the *parabasalia* or *sub-radialia*, after the *basalia* or these come one or more rows of plates (in *Rhizocrinus* three), the *radialia* (see fig. 23). In *Pentacrinus* the *radialia* seem to form the commencement of the calyx. Supported by the *radialia* are series of arm plates, or *brachialia*, from the uppermost of which, as in *Pentacrinus*, may bifurcate the *palmaria*. The ossicles of the arms are sometimes single, sometimes united by *syzygies*, or immovable sutures. In the Silurian genera *Anthocrinus* and *Crotalocrinus* the subdivisions of the arms are very numerous, and by their lateral articulation form web-like expansions. The arms of *Poteriocrinus plicatus* bifurcate 4 times, giving 80 rays; the total number of plates in that species has been estimated at 1300 (see J. G. Grenfell, *Rep. Brit. Assoc.*, 1875, p. 65). In the calyx of the *Tessellate* there are plates, *interradialia*, present between the *radialia*. In *Antedon* the central portion of the viscera is contained in a basin formed by the 1st, 2d, and 3d *radialia*, and by the 1st and 2d pairs of *brachialia*, and the basal

segments of the pinnules borne by the second; and the calycine cavity is completed by the perisome uniting the basal segments of the arms. Where, as in the *Articulata*, represented by the modern Crinoids, the disk is more or less membranous, four or five deep furrows radiate upon its surface from the mouth, which pass on to the oral surface of the arms and extend to the extremity of their pinnules. They carry the hollow ambulacral tentacles, which pass out through pores in the perisome. In 1865 Mr J. Rofe demonstrated (*Geol. Mag.*, ii. 215) in the case of several genera of Tesselate Crinoids from the Mountain Limestone (*Actinocrinus*, *Amphocrinus*, *Cyathocrinus*, and *Platycrinus*) that the groove on the upper surface of the arms divides at their base into two channels—(1) a superior channel passing up beneath (in some cases partly within) the plates of the dome or disk to its apex, and there uniting with an internal circular aperture, probably the mouth; and (2) an inferior channel which goes direct into the visceral cavity. These channels, since their discovery by Mr Rofe, have been shown to be generally present in the Tesselate Crinoids. The superior channels, on the supposition that the central opening is a mouth, doubtless served for the supply of food and of water for respiration; whilst the inferior channels probably gave passage to the motor muscles of the arms, and placed the visceral cavity in connection with the ovaries, if the latter, as in modern Crinoids, were situated in the arms. In the Palæozoic genus *Rhizocrinus* the arm is cylindrical, and without a groove on the upper surface, but immediately below its base is situated the orifice of a passage which turns upwards under the dome. What in the Palæozoic Crinoids is commonly regarded as the anal opening, is situated at the extremity of a probosciform tube (fig. 24) interradially placed, and often of great length—as much as 4½ inches in *Poteriocrinus plicatus*. In existing Crinoids there are two apertures in the disk—the mouth, usually central, as in *Rhizocrinus*, and the interradially situated anus. The mouth is closed by lobes of the perisome, the *oral valve*, which may contain calcareous plates. Between these run the oral or ambulacral grooves from the mouth to the arms. In *Antedon* (*Comatula*) the alimentary canal passes obliquely downwards from the mouth, then horizontally, and after more than a complete turn bends upwards again, and ends in a rectal chamber terminating in a spout-like prominence. Between the exterior of the mucous wall of the alimentary canal and its peritoneal covering is the intramural space. The double wall of the canal is strengthened by calcareous disks, and it is by the folding of the inner side of the wall, and the resultant piling together of layers of these plates that Fig 24 — *Dendrocrinus longicaudatus*. A, calyx. B, proboscis.

The ambulacral furrows are bordered by plates, the *ambulacral* or *marginal lamellæ*, as in *Rhizocrinus* and *Pentacrinus*, or, as in *Antedon*, by elevated ridges of the perisome, produced at the edge into a series of small lobes or valvules, and having grouped on their inner side the pedicels. The epithelial floor of the grooves, there is good reason to believe, is lined with cilia, which, like those of the gullet, serve to create currents in the water and thus to bring into the mouth Diatomacea, spores of Algae, minute Entomostraca, and other nutritive material.

In *Antedon*, as has been shown by Dr Carpenter

(fig. 25), the tentacles communicate at their bases with a common trunk, the *tentacular canal*. Beneath this, but having no communication with it, lies the *subtentacular canal*, which is usually divided by a more or less incomplete septum. Each of the subtentacular canals is continuous with a branch of the *axial canal*, which communicates with the deeper portion of the perivisceral cavity by means of a minute pore situated nearly at the centre of the lower surface of the visceral mass, and partly occupied by the pedicel before referred to. As the axial canal extends downward through the visceral mass it comes into contiguity with the alimentary canal, and opens into it by irregular passages. There is in the arms a third canal, the *coeliac*, which is a continuation of the body-cavity or coelom, and is separated from the subtentacular canal by a transverse partition. At the junction of this partition with the septum of the subtentacular canal there is a passage, the *genital canal*, in which lies the cellular cord known as the *generative rachis*, in connection with the visceral genital tissue. Enlargements of the rachis in the pinnules constitute the gonital glands of the Crinoid, the products of which may or may not be discharged by special orifices. Towards the extremity of the pinnules, in *Antedon*, the partition between the coeliac and subtentacular canals thins away, and becomes finally obsolete, thus possibly affording a means for the circulation of the nutritive fluid of the body, the subtentacular canals constituting an arterial or distributive and the coeliac a venous or collective system of vessels.

From the arms the tentacular canals proceed inwards to unite with a circular canal situated around the gullet, and having connected with it numerous short processes similar to the *vasa ambulacralia cavi* of the Ophiuridea (see page 635). There is no madreporic tubercle, and the madreporic canal is apparently unrepresented in the Crinoid. Respiration seems to be effected by the tentacles, and in *Comatula* also by the access of water through pores in the oral perisoma, communicating with a series of sinuses below its under surface by means of funnel-shaped canals. The central organ of the nervous system in *Antedon*, according to Carpenter, is the dilated cortical portion of the axis of the stem within the centro-dorsal plate, which supplies branches to the cirri and the arms, and corresponds probably with the axial sheath which, in *Pentacrinus*, sends off cords at the nodes of the stem into the whorls of cirri (see fig. 21). A fibrillar band underlying the epithelial floor of the brachial furrows is regarded by Ludwig as a nerve—"an afferent rather than a motor nerve" (Carpenter).

The development commences with the formation from the egg of an oval morula, which acquires four hoop-like ciliated bands, and a posterior terminal tuft of cilia. An endodermal sac or archenteron results from an invagination of the blastoderm between the third and fourth ciliated bands; and from this three diverticula, two lateral and one ventral, take their rise, the remainder of the archenteron becoming an alimentary cavity communicating with an anterior oesophagus. The lateral diverticula are transformed into peritoneal sacs, one on the dorsal the other on the ventral side of the alimentary cavity, and their walls coming in contact produce a circular mesentery. In the ventral diverticulum the ambulacral vessels have their origin. Around the alimentary cavity, when the pseud-embryo is scarcely a line in length, there are formed two circles, each of five calcareous plates, which eventually become the oral and basal ossicles of the calyx. From the centre of the posterior circle extends a row of eight calcareous rings, the future stem of the Crinoid, surrounding a backward prolongation of the dorsal

peritoneal sac. At the posterior extremity of the row is a eribriform disk, by which the young Crinoid subsequently attaches itself. The sacculic body of the pseud-embryo begins to shrink, the pseudostome and the two lower bands of cilia disappear, and afterwards the two upper bands, and the embryo then becomes fixed to a stone, seaweed, or some other object. A new mouth is formed in the centre of the disk by the separation of the oral plates, and the intestine by the production of a diverticulum of the alimentary cavity. In the early Pentacrinoid stage of *Comatula* the basals rest upon the centro-dorsal segment, but become at length metamorphosed into a single piece, the *rosette*; and the centro-dorsal segment by degrees increasing in size, the first radials come to rest upon its enfolded lip. During the same period, after the formation of an anus, the oral and basal plates disappear. The development of the dorsal cirri takes place as the proximal joint of the column enlarges to form the centro-dorsal piece. At the end of five or six months, when about $\frac{1}{2}$ an inch in diameter, the young *Comatula* detaches itself from its stalk, and is then able to swim by means of its arms. The Pentacrinoid larval form of *Comatula* (fig. 26), previous to his discovery of the ultimate stages of its growth, had been termed by Vaughan Thompson *Pentacrinus europaeus*.

The Crinoidae are classified as follows—

Order I. *Tessellata*. Calyx completely formed of calcareous plates, oral face without ambulacral furrows.

Family. *Tessellata*. Ex. *Cyathocrinus*, *Actinoecrinus*.

Order II. *Articulata*. Oral face of calyx usually membranous or sub-membranous, with ambulacral furrows.

Family 1. *Pentacrinida*. Always attached. Ex. *Pentacrinus*, *Rhizocrinus*.

Family 2. *Comatulidae*. Attached only in the young state. Ex. *Antedon*, *Phanogenia*. The Cretaceous genus *Marsupites* appears to have been unattached.

The Crinoidae are represented by *Glyptocrinus*, *Eucalyptocrinus*, *Marsupocrinus*, *Tarocrinus*, *Ichthyocrinus*, *Pericrinus*, *Cypriocrinus*, *Poteroocrinus*, *Woodocrinus*, *Cyathocrinus*, *Rhodocrinus*,

and numerous other genera in Palaeozoic strata, where their remains, especially in the Carboniferous series, are often the chief constituents of vast masses of compact limestone.¹ From their form the insculptured articuli of the stem have come to be known as *entrochi*, *scoriotones*, or *wheel-stones*, and in the north of England, as "St Cuth-

¹ On Crinoidal Limestone, see J. Rife, F.G.S., *Geol. Mag.*, x p. 262.

bert's beads " Among the various forms by which the Crinoidea were represented during the Mesozoic period, towards the close of which they diminished materially in number, are *Encrinurus* (Muschelkalk), *Extracrinurus*, *Pentacrinurus* (Lias), *Comatulidae* (Rhetie), *Apocrinurus*, *Millericrinurus*, *Eugenicrinurus*, and such forms as *Saccosoma* and *Pterocoena*, related to *Comatula* (Jurassic), and *Bourguetierinurus*, *Marsupites*, and (?) *Comatulidae* (Chalk) The Tertiary genera are but few They include *Bourguetierinurus* and *Cainocrinurus* (London Clay), and *Comatula* (Coraline Crag) *Pentacrinurus*, *Rhizocrinus* (allied to *Apocrinurus* and *Bourguetierinurus*) and the related forms *Bathycrinurus* and *Hyoecrinurus*, the sessile genus *Holopus*, *Actinometra*, and *Comatula* are living forms

Order V.—CYSTIDEA.—The body in the Cystidea is in most cases rounded, and is covered with polygonal plates; it is attached by a stem, and may be provided with arms or pinnules developed from the upper or oral surface. The stem is short, usually similar to that of the Crinoidea in construction, but without cirri, the joints are rounded, and sometimes moniliform, and usually become broader but thinner towards the base of the body. In *Ateleocystites* (see H. Woodward, *Geol. Mag.* 1871, p. 71) the calyx is compressed laterally, and shows sculpturing similar to that of the plates of the pedunculated *Curripedia* The plates of the calyx are pentagonal, hexagonal, or imperfectly triangular, and are closely united together, they vary in number, and in *Sphaerontes* (1 in fig 28) are very numerous In *Cryptocrinus* the calyx is composed of three rows of plates, which may be regarded as basalia, parabasalia, and radialis. According to Professor E Forbes (*Mem. of the Geolog. Survey of Great Britain*, 1848, vol. ii part 2), the following series of plates may be generally distinguished—a basal series, subovarian, centro-lateral, and supra-ovarian series on a plane below, on the same plane with, and on a plane above the ovarian pyramid respectively, circa-ovarian

plates or ossicles, encircling that structure, and oral plates, immediately surrounding the mouth, which vary considerably in number (fig 29) The plates are frequently ornamented with grooves and tubercles. Arms and pinnules are not universal. In *Comarocystites punctatus*, Billings, the arms are free, sometimes they are wanting, and the pinnules are attached to the upper portion of the calyx. Commonly the arms resemble ambulacra, and are reflected towards the base of the calyx, and closely applied to its surface Pores on the antambulacral surface may be absent (*Cryptocrinus*), irregularly scattered (*Caryocrinus*), in pairs (*Sphaerontes*), or, as in *Pseudocrinus* (2 in fig 28), *Echinoencrinurus*, and other genera, slit-like, and arranged to form "pectinated rhombs," or "hydrospires," the two halves of each rhomb being on separate plates.

In *Caryocrinus ornatus* there are thirty pectinated rhombs, consisting each of a number of parallel internal flat tubes communicating at both ends with pores opening internally The rhombs in *Pseudocrinus* are not tubular as in *Caryocrinus*, but are made up of numerous parallel inward folds of an exceedingly thin part of the test Again in *Palaeocystites tenuiradiatus* the whole surface bears rhombs, which, when uninjured, have a complete though very

thin calcareous covering, and communicate by a small pore at their base with the body-cavity (See Billings, *Ann. and Mag. of Nat. Hist* 1870, p 259-61)

What is usually regarded as the mouth is situated in the centre of the ventral surface of the calyx, opposite the point of attachment of the stem, and from it radiate the furrows for the arms, when those appendages are present. It is apparently small and circular in *Sphaerontes*, in *Caryocystites* it is transversely elongated and lobed; in *Hemicosmites* elevated on a proboscis; in *Echinoencrinurus* usually longitudinal and bordered by peculiar plates. A small perforation alongside the mouth, considered to be the anus, is generally present. It has sometimes, as in *Echinoencrinurus* (fig 30) and *Apiocystites*, the form of "an

FIG 28 Cystidea. 1. *Sphaerontes aurantium*, Wähl., Silurian, Sweden 2. *Pseudocrinus bifasciatus*, Pearce, Silurian, Dudley

FIG 29 — *Echinoencrinurus armatus*, dissection and projection of plates (After Forbes.) 1-4, basal, 5-9, subovarian, 10-14, centro-lateral, 15-19 supra-ovarian, c, genital pyramid and plates Plates 1, 5, 14, and 15 bear semi-rhombs

FIG 30 — *Echinoencrinurus armatus* (After Forbes) a, mouth, b, anal aperture, and c, ovarian pyramid of the same, enlarged

arched or crescentic groove terminating apparently at each end with a pore, and having united with it, or placed a little below it, an orifice in the middle line of a suture, as if in the junction of two oral plates" (Forbes). Almost invariably, on the oral portion of the body, interradially placed, is a round or oval aperture covered by a pyramid of 5 or 6 triangular valves. This in the opinion of most authorities is probably the ovarian orifice, but according to Mr Billings it is an oro-anal aperture, the central opening or mouth above mentioned being an "ambulacral orifice." *Cystidea* first occur in strata of Cambrian age. They especially characterize the Lower and Upper Silurian series of rocks, and apparently died out in the Carboniferous epoch.

Order VI.—EDRIOASTEREIDA.—Under this head are grouped such forms as *Edrioaster*, *Agelacrinites*, and *Hemicystites* The shape is that of a rounded star-fish or flattened echinus with a concave base. There is an ovarian pyramid, but stem and arms are wanting, and the ambulacra communicate by perforations with the calycine cavity. The Edrioasterida are exclusively Palaeozoic. Their nearest living ally is the Australian species *Hyponome Sarsii*, Lov., which approaches *Agelacrinites* in form

Order VII.—BLASTOIDEA.—In this group of fossil Echinoderms the bud-shaped or prismatic, armless, and closely plated calyx is supported on a short, jointed stem. Of the three basal plates in *Pentremites* two are double, succeeding the basals is a row of five pieces, and into the deep clefts of the upper portion of these fit the lower ends or apices of the ambulacra, a third series of five small, deltoid, inter-radial plates occupy the spaces between the oral portions of the ambulacra. The ambulacra, or "psendambulacral areas," present a superior surface formed by a double series of ossicles running from a median line to the border, where they support pinnules; beneath the ossicles is usually a lanceolate plate formed in many if not all species of *Pentremites* of two contiguous plates, and edged by a simple row of transverse pieces, which are pierced with marginal pores

FIG 31 *Pentremites florealis*

Each row of pores opens below into one or more flat canals, or, according to the definition of Billings (*Ann. and Mag. of Nat Hist*, vol v. 4th ser p. 263), into a "hydrospire" consisting of "an elongated internal sac, one side of which is attached to the inside of the shell [or

test], while the side opposite, or towards the central axis of the visceral cavity, is more or less deeply folded longitudinally" (see fig. 32). These internal canals, as suggested by Roze, may possibly represent the tubes under the dome of the Crinoidea. In *Codonaster* the ambulacra are confined to the upper portion only of the calyx. Pores and attached tubes are wanting; but there are striated structures between the arms, similar in appearance and probably also in function to the pectinated rhombs of the *Cystidea*, their ridges, as first shown by Roze (*Geol. Mag.*, 1865, ii. p. 251), being the tops of a series of folds of a thin test or membrane, which were perhaps "respiratory sacs, lined with cilia, and constructed of a porous test, through which air from the water could pass by diffusion." The expanded ends of the neighbouring tubes of each two ambulacra form at the summit of the test four double and two single apertures commonly termed "ovarian orifices;" between the two latter there is usually a third, apparently anal, opening. In *Eleutheroerinus* there are three paired, and two single pores only. The Blastoidea, which are (?) represented by *Pentremites* in Upper Silurian strata, attained their principal development during the Carboniferous epoch, at the close of which they seem to have become extinct.

Order VIII.—HOLOTHURIDEA.—The Holothuridea, Sea-slugs, Trepangs, or Sea-cucumbers (figs. 33 and 34) have a

FIG 32.—Transverse section of ambulacrum of *Pentremites Godoni*, x3. (After Billings.)

l, lumen; p, pore; c, canal; c, c.

spiculae, which vary much according to the species, and may take the shape of perforated disks, wheels, anchors, and hooks (fig. 35). Rarely the dorsal integument may develop an armature of overlapping plates (*Psolus*), which may bear spines (*Echinocucumis*). Underlying the perisome is a layer of circular muscular fibres, some of which pass into the mesenteries; a second internal set of five simple or paired bands of longitudinal muscular fibres are attached at one end to the radial pieces of the calcareous oral ring, and supply branches to the oral tentacles, and at the other are inserted into the sphincter of the anus. It is by means of the

longitudinal muscles that the Holothurid, when irritated, effects the discharge of its viscera at the hinder extremity of its body. In the midst of a circle of tentacles, five or multiples of five in number, is the mouth, which is without dental apparatus. The tentacles vary considerably in shape, and may be cylindrical, shield-shaped, pinnate, or ramified. They serve as organs of touch, of nutrition, and occasionally also of locomotion. The alimentary canal is simple, and usually longer than the body, so as to be two or three times folded on itself, it is attached to the interior surface of the body by mesenteries, and may terminate in a cloaca. Its walls are composed of an external layer of circular, and an internal layer of longitudinal muscular fibres, and an innermost cellular lining. In common with the peritoneal surface of the body, it is ciliated. Two, or more rarely four or five, branched processes of the cloaca, the *respiratory trees* or *water-lungs*, are ordinarily present, and are connected to the body-wall by a mesentery or by threads (fig. 36). They appear to be excretory in function, water being continually passed into and out of them through the contractile cloaca. Their ultimate ramifications terminate in minute openings, by means of which they appear to have communication with the peritoneal cavity. In *Echinocucumis* the respiratory trees are only single-branched. In *Synapta*, in which they do not occur, there are funnel-shaped ciliated bodies attached to the mesentery of the alimentary canal. The respiratory tree occupying the ventral left interradial space has been observed in many cases to be surrounded by a plexus of the pseudohæmal system of vessels.

What are termed *Cuvierian organs* are appendages of the cloaca, which, according to Semper (*Reisen in Archipel der Philippinen*, 1 pp. 139, 140), are muscular, and can be used as a means of defence, being capable of protrusion externally. The main trunks of the pseudohæmal system, which is often exceedingly complex, are two vessels, one on the dorsal, the other on the ventral face of the intestine, which are connected with each other by capillary reticulations. The calcareous ring surrounding the gullet, already referred to,

consists usually of five interradial, and five notched or perforated radial plates united by muscles—the homologues of the auricular of the Echinidea. A circle of plates, in certain species, surrounds the anus. The fluid filling the various canals of the ambulacral system contains nucleated cells. The ambulacral circular vessel lies behind the calcareous ring, it gives off from one to five or more Pohan vesicles, also one or more madreporic canals. Calcareous spicules are contained in the wall of the madreporic canal, and often it is terminated at the free end by a cribriform plate similar to a madreporite. By means of the madreporic canal the ambulacral vessels communicate with the peritoneal cavity. From the ambulacral ring there proceed five, sometimes more tentacular canals, which supply caecal branches to the tentacles, and usually, also, five ambulacral canals, which give rise to as many rows of pedicels situated in most cases radially, and forming a dorsal bivium and ventral trivium. Sometimes, as in *Psolus*, the pedicels are irregularly dispersed over the whole perisome, or they may be met with only on the lower surface of the body, where they subserve locomotion. In *Molpadia* and its allies there are ambulacral canals, but no pedicels; in the *Synaptidae* the canals are wanting. The sexual organs are one or two groups of branched tubuli, which open either on the dorsal surface or between the two dorsal tentacles. Except in the *Synaptidae*, and apparently also the *Liodermatidae*, the sexes are distinct. The nervous system consists of a circular cord, lying above the ambulacral ring, and giving off five apparently hollow branches, which pass through holes or notches in the radial plates of the calcareous ring, to proceed down the centre of the longitudinal muscular bands of the body.

Development is direct in *Holothuria tremula* and *Pentacta doliolum*, and a species of *Synapta* is viviparous. The majority of the Holothuridea undergo metamorphoses, during which, however, no portion of the echinopodium is discarded. By invagination of the morula an intestinal cavity is produced, into which an ectodermic invagination opens, forming the upper portion of the alimentary canal. The cilia that at first clothe the body commonly become limited to a doubly bent band, the larva developing into an *auricularia*, which has sac-like processes, and occasionally spicules, but never a skeleton. Growing less transparent, the *auricularia* loses its lateral processes, the mouth disappears, and the larva reaches the "pupa-stage," in which the body is surrounded by five ciliated hoops. A new mouth with tentacles is now developed, the ciliated bands are lost, and the animal attains the same shape as the adult. The peritoneal cavity and the ambulacral system both originate in a caecal process of the archenteron or primitive endodermal sac, which, separating from the latter, forms what has been termed the *vaso-peritoneal vesicle*. This gives off a process which opens on the dorsal surface, and which eventually furnishes the madreporic canal. A portion of the vesicle remains in connection with this process, and is transformed into the ambulacral vessels; the other portion becomes two sausage-shaped vesicles at the sides of the alimentary canal, above and below which they grow together, and form a continuous space, the future peritoneal cavity. The inner and outer wall of the chamber thus resulting become attached respectively to the parietes of the body and to the alimentary canal, and mainly contribute to the production of their peritoneal and muscular layers.

The Holothuridea are creeping in habit; some, however, of the *Synaptidae* are able to swim. The apodal forms move themselves by contractions of the body, and by means of their tentacles. The Holothuridea derive their nourishment from the sand which they swallow, and from Diatomaceae, Foraminifera, and other minute marine organisms. Among the internal parasites of the Holothuridea are small fishes of the genus *Fierasfer*, embryos of the gastropod *Eutocochoa mirabilis*, and Copepod crustaceans (*Pinnotheres*). Certain species of *Holothuria* are much esteemed in China as food, and constitute an important article of commerce with that country.

The Holothuridea may be grouped as follows—

I APNEUMONA. Respiratory trees and Cuvierian organs absent, mouth and anus at opposite ends of the body, ambulacral canals five; hermaphrodite.

(1.) *Synaptidae*. Pedicels absent. Ex. *Synapta*, *Chirodota*.

(2.) *Oncodermatidae*. Pedicels present. Ex. *Echinoma*.

II TETRAPNEUMONA. Respiratory trees four, body flask-like; mouth and anus at the same end of it, the former surrounded

by ten tentacles and ten calcareous plates, the latter by as many papillae and plates, five ambulacra diverge from the anal, and five from the oral region of the body; pedicels in two rows. Ex. *Rhopalodina lageniformis* only—the class *Diplostomidea* of Stimp.

III DIPNEUMONA. Respiratory trees two; Cuvierian organs present; mouth and anus polar; pedicels single ranked.

(1.) *Liodermatidae*. Pedicels absent; tentacles shield-like, cylindrical, or branched. Ex. *Liosoma*, *Haplodactyla*, *Molpadia*.

(2.) *Dendrochirotridae*. Tentacles branched. Ex. *Thyone*, *Phyllophorus*, *Ochnus*, *Psolus*.

(3.) *Aspidochirotridae*. Tentacles shield-like. Ex. *Aspidochirus*, *Stichopus*, *Sporadipus*, *Holothuria*.

Mr C Moore, F.G.S. (*Rep. Brit. Assoc.*, 1872, p. 117), has described wheel-like spicules of four species of *Chirodota*, one from the Inferior Oolite, one from the Upper Lias, and two from the Middle Lias. "They are formed of a number of minute wheel-spokes, varying from 5 to 13, which start from a central axis, and are surrounded on the outside by a wheel-tire, on the inner edge of some species are a series of very minute teeth, extending over the central cavity." Mr R Etheridge, jun. (in the *Memoirs of the Geol. Survey of Scotland, Explanation of Sheet 23, 1873*), has called attention to the discovery by Mr J Bienne, survey-collector, of similar organisms in the Lower Carboniferous Limestone group of E. Kilbride, and in shales of the Upper Limestone group of Williamwood, near Glasgow.

(F. H. B.)

ECHO, in Greek mythology, one of the Oracles or mountain nymphs. The word denotes mere sound; and the stories told of her are so transparent that they can scarcely be said to belong to the class of fully-developed myths. As Selene to the Greek was clearly the moon, so Echo was the being who could not speak until she was spoken to, and then could only repeat the last words of the speaker. This penalty is said to have been inflicted upon

her by Hera, whom the nymph by her chatter had prevented from discovering the sports of Zeus among her sister Oreades. Another tale relates that Echo fell in love with Narcissus, who was deaf to her entreaties, and that in her grief she wasted away until nothing remained but her bones and her voice. The name Narcissus, again, denotes one who is oppressed by lethargy, and thus the story becomes a counterpart to that of Selene and Endymion. Another legend speaks of her as being loved by Pan, the Latin Favonius, the soft and purifying breeze, and represents her lover as seeking in vain to see her form, although everywhere he hears her voice.—Ovid, *Met.* iii. 356 *et seq.*; Paus. ix. 31, 6.

For ECHO, in physics, see ACOUSTICS, vol. i. p. 107.

ECIJA, a city of Spain, in the province of Seville, 53 miles E.N.E. of the city of that name, on the left bank of the Jenil, Xenil, or Genil, the ancient Singulis, a tributary of the Guadalquivir. The river, thus far navigable, is there crossed by a fine old bridge; and the antiquity of the town betrays itself both by the irregularity of its arrangement, and by its walls and gateways, and its numerous inscriptions and other relics. Among its public buildings it numbers six parish churches, seven nunneries, thirteen secularized convents, two hospitals, a theatre, a foundling asylum, and barracks. The principal square is surrounded with pillared porticoes, and has a fountain in the centre; and along the river bank there runs a fine promenade, planted with poplar trees and adorned with statues. From an early period the shoemakers of Ecija have been in high repute throughout Spain; and woollen cloth, flannel, linen, and silks are manufactured in the town. The vicinity is fertile in corn and wine, and cotton is also cultivated to some extent. The heat is so great that the spot has acquired the sobriquet of El Sartén, or the Fryug-pan of Andalusia. Ecija, called Estija by the Arabs, is the ancient Astigis, which was raised to the rank of a Roman colony with the title of Augusta Firma, and, according to Pliny and Pomponius Mela, was the rival of Cordova and Seville. If local tradition may be believed, it was visited by the apostle Paul, who converted his hostess Santa Xantippa; and, according to one version of his life, it was the see of the famous Crispin. Among its modern celebrities the most remarkable is Luis Vulez de Gueraa, the dramatist. Population 27,216.

ECK, JOHANN MAIER VON (1486–1543), the most indefatigable and important opponent of Martin Luther, was born 13th November 1486, at Eck in Swabia. His father was a peasant, who becoming bailiff of the village, added Eck to the family name Maier. The son entered in his eleventh year the university of Heidelberg, from which he went to Tübingen, where he took his master of arts degree in his fourteenth year, and afterwards studied theology. He then went to Cologne, and afterwards to Freiburg, where, besides studying jurisprudence and mathematics, he taught philosophy. In 1506 he published a work on logic. From this time he appears to have devoted his attention chiefly to theology; and his skill and versatility in scholastic disputations having attracted considerable notice, the duke of Bavaria, in 1510, presented him to the chair of theology in the university of Ingolstadt. In 1515 he took part in a public disputation at Bologna, and in 1516 in one at Vienna, on both occasions gaining great admiration. In 1518 he circulated privately his *Obelisci* against Luther's thesis on the mass. Luther intrusted his defence to Carlstadt, who, besides answering the insinuations of Eck in 400 distinct theses, declared his readiness to meet him in a public disputation. The challenge was accepted, and the disputation took place at Leipsic in the following year. It lasted for three weeks, and Luther as well as Carlstadt opposed himself to Eck. The general

impression was that victory rested with Eck; but apparently success only embittered his animosity against his opponents, for from that time his whole efforts were devoted to Luther's overthrow. He induced the universities of Cologne and Louvain to condemn the Reformer's writings, and in 1520 went to Rome to obtain strict regulations against what he called the "Lutherans." He returned with the celebrated papal bull against Luther's writings, and with the commission to publish it, but at Leipsic met with so bad a reception from the inhabitants, that he was compelled to take refuge in the Pauline convent. Eck took a leading part in the Augsburg diet of 1530, and in the conferences at Worms in 1540 and at Ratisbon in 1541. He died in 1543. He is said to have been a bad linguist, and not an able theologian, but to have possessed great readiness and fluency, a retentive memory, and remarkable dexterity in sophistical argumentation. Among his numerous writings is a translation of the Bible, which was written to supersede that of Luther, but met with no success.

ECKERMANN, JOHN PETER (1792–1854), friend of Goethe, and editor of his works, was born at Winsen in Hanover, in 1792. After serving as a volunteer in the War of Liberation (1813–1814), he obtained an appointment in the war office at Hanover. At the age of twenty-five he became a student at the gymnasium of Hanover and afterwards at the university of Göttingen, returning to Hanover in 1822. His acquaintance with Goethe began in the following year, when he sent to him the manuscript of his *Beitrag zur Poesie*. Soon afterwards he went to Weimar, and was appointed private secretary to the poet. For several years he was also engaged as tutor to the son of the grand duke. In 1830 he travelled in Italy with Goethe's son. In 1838 he was named councillor of the grand duchy, and appointed librarian to the grand duchess. Eckermann is chiefly remembered for the important contributions to our knowledge of the great poet contained in his *Gespräche mit Goethe*, the first and second parts of which appeared in 1836, and the third in 1848. This work was first translated into English by Margaret Fuller, and published at Boston, U.S., in 1839. Another English translation, by John Oxenford, appeared in London in 1850. It has been translated into almost all the European languages, not excepting Turkish. To Eckermann Goethe intrusted the publication of his posthumous works (1832–1833). He was also joint-editor with Riemer of the complete edition of Goethe's works in 40 vols. (1839–1840). Eckermann died at Weimar, December 3, 1854.

ECKERSBERG, CARL VILHELM (1783–1853), Danish painter, was born in South Jutland in 1783. He became successively the pupil of Abildgaard and of David. From 1810 to 1813 he lived at Paris under the direction of the latter, and then proceeded, as an independent artist, to Rome, where he worked until 1816 in close fellowship with Thorvaldsen. His paintings from this period—The Spartau Boy, Bacchus and Ariadne, and Ulysses—testify to the influence of the great sculptor over the art of Eckersberg. Returning to Copenhagen, he found himself easily able to take the first place among the Danish painters of his time, and his portraits especially were in extreme popularity. It is claimed for Eckersberg by the native critics that "he created a Danish colour," that is to say, he was the first painter who threw off conventional tones and the pseudo-classical landscape, in exchange for the clear atmosphere and natural outlines of Danish scenery. But Denmark has no heroic landscape, and Eckersberg in losing the golden common-places scarcely succeeds in being delightful. His landscapes, however, are pure and true, while in his figure-pieces he is almost invariably conventional and old-fashioned. He became the president of the Danish Academy of Fine Arts in Charlottenberg, and died in 1853.

ECKHART, JOHANNES, or, according to the general designation, Meister Eckhart, the first of the great speculative mystics, flourished during the latter part of the 13th century and the early part of the 14th. Extremely little is known of his life; the date and place of his birth are equally uncertain. According to some accounts, he was a native of Strasburg, a town with which he was afterwards closely connected; according to others, he was born in Saxony. Trithemius, one of the best authorities, speaks of him merely as "Tentonicus" 1260 has frequently been given as the date of his birth; it was in all probability some years earlier, for we know that he was advanced in age at the time of his death, about 1327. He appears to have entered the Dominican order, and to have acted for some time as professor at one of the colleges in Paris. His reputation for learning was very high, and in 1302 he was summoned to Rome by Boniface VIII., to assist in the controversy then being carried on with Philip of France. From Boniface he received the degree of doctor. In 1304 he became provincial of his order for Saxony, and in 1307 was vicar-general for Bohemia. In both provinces he was distinguished for his practical reforms and for his power in preaching. In what manner he ceased to hold his high office we do not know; indeed, several years of his life about this time are a complete blank. Towards 1325 we hear of him as preaching with great effect at Cologne, where he gathered round him a numerous band of followers. Before this time, and in all probability at Strasburg, where he appears to have been for some years, he had come in contact with the BEGHARDS (*q. v.*) and Brethren of the Free Spirit, whose fundamental notions he may indeed be said to have systematized and expounded in the highest form to which they could attain. In 1327 the opponents of the Beghards laid hold of certain propositions contained in Eckhart's works, and he was summoned before the Inquisition at Cologne. The history of this accusation is by no means clear. Eckhart appears, however, to have made a conditional recantation—that is, he professed to disavow whatever in his writings could be shown to be erroneous. Further appeal, perhaps at his own request, was made to the Pope, and in 1329 a bill was published condemning certain propositions extracted from Eckhart's works. But before its publication Eckhart was dead. The exact date of his death is unknown. Of his writings, several of which are enumerated by Trithemius, there remain only the Sermons and a few tractates. Till recently the majority of these were attributed to Tauler, and it is only from Pfeiffer's careful edition (*Deutsche Mystiker d. XIV. Jahrhunderts*, vol. ii., 1857) that one has been able to gather a true idea of Eckhart's activity. From his works it is evident that he was deeply learned in all the philosophy of the time. He was a thorough Aristotelian, but by preference appears to have been drawn towards the mystical writings of the neo-Platonists and the pseudo-Dionysius. His style is unsystematic, brief, and abounding in symbolical expression. His manner of thinking is clear, calm, and logical, and he has certainly given the most complete exposition of what may be called Christian pantheism.

Eckhart has been called the first of the speculative mystics, but such a designation requires some qualification. Within the Christian church from the time of Erigena there had been a constant stream of what must be called mysticism, originating for the most part from the writings of the neo-Platonists and of Dionysius the Areopagite. This tendency may be noted in Bonaventura, in Albert (under whom Eckhart is said to have studied), and in Aquinas; it is more prominent in Hugo and Richard of St Victor, though with them it took a practical rather than a speculative direction. But in all these writers, with the

partial exception of Erigena, who occupies a quite peculiar position, the mystical element was in strict subordination to the church doctrines, which might be speculatively symbolized, but were not thereby explained or rationalized. In Eckhart's writings and preaching, on the other hand, the element of mystical speculation for the first time comes to the front as all-important. By its means the church doctrines are made intelligible to the many, and from it the church dogmas receive their true significance. It was but natural that he should gradually diverge more and more widely from the traditional doctrine, so that at length the relation between his teaching and that of the church appeared to be one of opposition rather than of reconciliation. Eckhart is thus in truth the first who attempted with perfect freedom and logical consistency to give a speculative basis to religious doctrines.

It is not possible to expound in detail how Eckhart endeavours to explain the main principles of the Christian faith, but it is necessary to note the two most important points in his as in all mystical theories. These are first, his doctrine of the divine nature, and second, his explanation of the relation between God and human thought. The two are logically connected, and a complete exposition of his theory might start from either his theology or his psychology. Lasson, the author of a most valuable monograph on Eckhart, adopts the latter course, but for many reasons the other appears the most systematic.

The fundamental thought from which Eckhart's theology starts is that of the Absolute or Abstract Unity as the only real existence. Apart from God no thing has real being. But this Absolute is, for Eckhart, the *Deus absconditus*, the *Θεὸς ἄκρυπτος* of the neo-Platonic theology. With Dionysius the Areopagite, Eckhart describes this divineness, the Godhead, as absolutely without predicates; all determinations are limitations which destroy its infinite being. The Godhead is incomprehensible, inexpressible. It is in truth nothing, yet as the most real of beings it must be conceived as absolutely potential, as containing in itself the origin and final end of all things. This Godhead is not God as known to us. From the Godhead the triune God proceeds or is evolved. At this point, at the transition between the divine absolute and the personal deity, Eckhart is face to face with the crucial difficulty of all speculative mysticism, and it is of interest to compare his method of solution with that adopted by later thinkers of like tendencies, *e. g.*, Boehme and Baader. In the Godhead, as in everything, according to Eckhart, there must be distinguished matter and form, or, as they are here called, essence and nature. The matter or essence is the potentiality, what the thing is in itself, the form or nature is that which it becomes as an object for others. The Godhead reveals itself in the personal God, the Father. For the Godhead is a spiritual substance, and as such can only become real by consciousness, by reflection on self, by self-expression. That which reflects and expresses is the Father. The Son is the Word, or expression through and in which the Father becomes self-conscious. As there is here no distinction of time or space, Father and Son are in very truth one. The Father eternally begets the Son, and the return of the Son into the Father in love and mutual will is the Spirit. The Father is not before the Son; only through the begetting of the Son, only through arriving at self-consciousness, does He become the Father.

The genesis of the Son from the Father involves also, according to Eckhart, the production of the world of things. For God is reason, and in reason is contained the ideal world, the world of creatures, not in time and space, which becomes materialized. In the Son are all things made, but only, Eckhart is careful to point out, in ideal form. He holds strongly to the so-called Platonic view that, over and above sensible things, there exists a realm of ideal forms or exemplars, to be apprehended by pure thought, through thought freed from the limitations of space and time. How this ideal world is related to the world of real things he does not show, nor does he explain the apparent independence of the material universe. When, therefore, Eckhart speaks of the world as necessary to the divine existence, of God as loving Himself in created things, and of all things being God, he must be understood to speak of this ideal world, not of things as known to us.

As all things have arisen from God, so all things desire to return into the unity of the divine being. Repose in God is the final end of all things. In man, the noblest of created things, this return is brought about. In man, specially, there is the faculty of suprarational cognition, the power of reaching to the absolute, the ground both of God and of the universe. This peculiar power, called

by Eckhart the spark (*Funklein, Scintilla*), is in truth God working in man. In cognition of God, God and man are one; there is no distinction of knower and known, and hence, as opposed to empirical knowledge, it may be called faith. In such faith, there is involved not only reason, but will, for the divine illumination becomes operative or takes real effect through the will.

To attain to full union with God is the final end of activity, and the means, it is clear, must be the resignation of all individuality. Absolute quietism appears to be the only method whereby the birth of the Son in the soul may be brought about. When this state has been reached, then the human soul is one with God; its will is God's; no evil can be wrought by it; it cannot sin. The practical consequences which would flow from such a doctrine, and which did appear among the Brethren of the Free Spirit, were evaded, rather than overcome, by Eckhart. For, according to his teaching, all the above applies only to the "spark" in the soul; the other faculties may be reasonably and legitimately employed about other and temporal matters. By this loop-hole, also, he escapes the doctrine that works are entirely inefficacious. He is careful to hold the balance between inward feeling and outward action, and on this point his teaching is important in relation to the later Reformation thinkers.

On the specifically theological doctrines of Eckhart, such as Grace, Incarnation, the Fall, Redemption and Sin, it is not possible to enter in brief compass. A most adequate account of them will be found in Lasson's monograph above referred to.

The most important of the many works upon Eckhart are—Pfeiffer, *Deutsche Mystiker*, vol. II.; Martensen, *Meister Eckhart*, 1842; Bach, *Meister Eckhart der Vater der Deutschen Speculation*, 1861; Lasson, *Meister Eckhart der Mystiker*, 1888; Ullmann, *Reformatoren vor der Reformation*, 1842; Preger, *Geschichte d. Deutschen Mystik*, I., 1874.

ECKHEL, JOSEPH HILARIUS (1737–1798), one of the most distinguished numismatists, was born at Enzersfeld in Lower Austria, January 13, 1737. His father was farm-steward to Count Zinzendorf, and he received his early education at the Jesuit's College, Vienna. Here at the age of fourteen he was admitted into the order, still pursuing his studies with earnestness, and especially devoting himself to antiquities and numismatics. After being engaged professor of poetry and rhetoric, first at Steyer and afterwards at Vienna, he was appointed in 1772 keeper of the cabinet of coins at the Jesuit's College, and in the same year he went to Italy for the purpose of personal inspection and study of antiquities and coins. At Florence he was employed to arrange the collection of the grand duke of Tuscany; and the first fruits of his study of this and other collections appeared in his *Numi Veteres Anecdoti*, published in 1775. On the dissolution of the order of Jesuits in 1773, Eckhel was appointed by the empress Maria Theresa professor of antiquities and numismatics at the university of Vienna, and this post he held for twenty-four years. He was in the following year made keeper of the imperial cabinet of coins, and in 1779 appeared his *Catalogus Vindobonensis Numorum Veterum*. Eckhel's great work is the *Doctrina Numorum Veterum*, in 8 vols., the first of which was published in 1792, and the last in 1798. The author's rich learning, comprehensive grasp of his subject, admirable order and precision of statement in this masterpiece drew from Heyne enthusiastic praise, and the acknowledgment that Eckhel, as the Coryphæus of numismatists, had, out of the mass of previously loose and confused facts, constituted a true science. A volume of *Addenda*, prepared by Steinbuechel from Eckhel's papers after his death, was published in 1826. Among the other works of this great scholar are—*Choix de Pierres gravées du Cabinet Imperial des Antiques* (1788), a useful school-book on coins entitled *Kurzgefasste Anfangsgründe zur alten Numismatik* (1787), of which a French version enlarged by Jacob appeared in 1825, &c. Eckhel died at Vienna, May 16, 1798.

ECLECTIC (from ἐκλέγω, I select), a term of which the most important application is in philosophy, denotes a thinker whose views are borrowed partly from one, partly from another, of his predecessors. It perhaps requires to be noted that, where the characteristic doctrines of a philosophy are not thus merely adopted, but are the modified products of a blending of the systems from which it takes its rise, the philosophy is not properly eclectic.

The history both of ancient and of modern eclecticism shows that eclecticism naturally springs up when, while literary culture makes the doctrines of the chief philosophies familiar and preserves an interest in philosophy, the first pursuit of thinkers is not purely speculative truth.

In the 2d century B.C., a remarkable tendency toward eclecticism began to manifest itself. The longing to arrive at the one explanation of all things which had inspired the older philosophers became less earnest; the belief, indeed, that any such explanation was attainable began to fail; and thus men, not feeling the need of one complete logical system, came to adopt from all systems the doctrines which best pleased them. In Panætius we find one of the earliest examples of the modification of Stoicism by the eclectic spirit; and about the same time the same spirit displayed itself among the Peripatetics.

The philosophy that took root in Rome, where philosophy never became other than a secondary pursuit, was naturally for the most part eclectic; of this Cicero is the most striking illustration,—his philosophical works consisting of a mixture, with little or no blending, of doctrines borrowed from Stoicism, Peripateticism, and the scepticism of the Middle Academy. And, not to mention numerous names of minor importance, eclecticism had another representative at Rome in the school of Sextus and Sotion, who were half Stoic, half Pythagorean.

In the last stage of Greek philosophy the eclectic spirit produced remarkable results outside the philosophies of those properly called eclectics. Thinkers chose their doctrines from many sources—from the venerated teaching of Aristotle and Plato, from that of the Pythagoreans and of the Stoics, from the old Greek mythology, and from the Jewish and other Oriental systems. Yet, it must be observed that neo-Platonism, Gnosticism, and the other systems which are grouped under the name Alexandrian, were not truly eclectic, consisting, as they did, not of a mere syncretism of Greek and Oriental thought, but of a mutual modification of the two. It is true that several of the neo-Platonists professed to accept all the teaching both of Plato and of Aristotle, but, in fact, they arbitrarily interpreted Aristotle so as to make him agree with Plato, and Plato so as to make his teachings consistent with the Oriental doctrines which they had adopted, in the same manner as the schoolmen attempted to reconcile Aristotle with the doctrines of the church. Among the early Christians, Clement of Alexandria, Origen, and Sinesius were eclectics in philosophy.

The eclectics of modern philosophy are too numerous to name. Of Italian philosophers the eclectics form a large proportion. Among the German we may mention (though details cannot here be given) Wolf and his followers, as well as Mendelssohn, Eberhard, Platner, and to some extent Schelling, whom, however, it would be incorrect to describe as merely an eclectic. In the first place he cannot be denied the praise of originality; and, in the second place, it is not so much that his views of any time were borrowed from a number of philosophers, as that his thinking was influenced first by one philosopher then by another.

But, during the present century, the term eclectic has come to be specially applied to a number of French philosophers who differ considerably from one another. Of these the earliest were Royer-Collard, who was mainly a follower of Reid, and Maine de Biran; but the name is still more appropriately given to the school of which the most distinguished members are Victor Cousin, Théodore Jouffroy, Damiron, St Hilaire, Rémusat, Garnier, and Ravaisson. Cousin, whose views varied considerably at different periods of his life, not only adopted freely what pleased him in the doctrines of Laromignière, Royer-Collard, and Maine de Biran, of Kant, Schelling, and Hegel, and of

the ancient philosophies, but expressly maintained that the eclectic is the only method now open to the philosopher, whose function thus resolves itself into critical selection and nothing more. "Each system," he asserted, "is not false, but incomplete, and in reuniting all incomplete systems, we should have a complete philosophy, adequate to the totality of consciousness." But this assumes that every philosophical truth is contained somewhere in the various philosophies, and if, as it would be surely rash to deny, there still remains philosophical truth undiscovered, but discoverable by human intelligence, it is evident that eclecticism is not yet the only philosophy. For a discussion of the question how far the above dicta of Cousin represent his own method of philosophizing we must refer the reader to the article COUSIN. Eclecticism gained great popularity, and, partly owing to Cousin's position as minister of public instruction, became the authorized system in the chief seats of learning in France, where it has given a most remarkable impulse to the study of the history of philosophy.

ECLIPSE. See ASTRONOMY.

ECSTASY (*ἔκστασις*, from *ἐξίστημι*, to put out of its place, to alter), a term applied to a morbid mental condition, in which the mind is entirely absorbed in the contemplation of one dominant idea or object, and loses for the time its normal self-control. With this there is commonly associated the prevalence of some strong emotion, which manifests itself in various ways, and with varying degrees of intensity. This state resembles in many points that of catalepsy already described, but differs from it sufficiently to constitute it a separate affection. The patient in ecstasy may lie in a fixed position like the cataleptic, apparently quite unconscious, yet, on awaking, there is a distinct recollection of visions perceived during this period. More frequently there is violent emotional excitement, which may find expression in impassioned utterances, and in extravagant bodily movements and gesticulations. This disease usually presents itself as a kind of temporary religious insanity, and has frequently appeared as an epidemic. It is well illustrated in the celebrated examples of the dancing epidemics of Germany and Italy in the Middle Ages, and the *Convulsionnaires* of St Medard at the grave of the Abbé Paris in the early part of the last century, and in more recent times has been witnessed during periods of religious excitement in this country. This disorder is highly contagious, and readily spreads by imitation. As a disease it is more curious than important, and for its treatment requires the judicious exercise of moral influences rather than medical remedies, although these also, as in the case of similar ailments, may often be used with advantage.

ECUADOR, or, in full, LA REPUBLICA DEL ECUADOR, an independent state of South America, traversed by the equator, from which it takes its name, and bounded on the N. by the United States of Colombia, E. by Brazil, S. by Peru, and W. by the Pacific Ocean (see plate xi. vol. i.). Its area cannot be stated with any close approximation to accuracy, for large districts along the frontiers are equally claimed by Ecuador and the neighbouring powers, and even within the limits of undisputed possession no systematic survey has been undertaken. According to Villavicencio, the area is only 127,205 English square miles; but F. Hanemann, quoted by Behm and Wagner (*Bevölkerung der Erde*, 1874, p. 76), makes it 248,580 by planimetric calculation on the basis of H. Kiepert's map in his *Handatlas*, 1872. Kiepert places the eastern limit at 70° W. of Greenwich, but does not assign to Ecuador the disputed territory along both sides of the Marañon. The population was stated by Villavicencio at 1,108,082 in 1857, exclusive of 200,000 "wild" Indians; but an official estimate for the same year is quoted by Wappaus, which gives only 381,943, exclusive of 150,000 "wild" Indians, and

even this he thinks is probably too high. His opinion is so far confirmed by the memoir of the minister Leon, published in 1875 at Quito, according to which the total population, exclusive of about 200,000 Indians, was 866,137. The Galapagos Islands, an uninhabited group with an area of 2951 square miles, are dependent on Ecuador.

Mountains.—The great South American chain of the Andes traverses Ecuador from south to north, and forms the predominant factor in its physical constitution. Its two Cordilleras run parallel with each other, and inclose an elevated longitudinal valley about 40 miles wide and 300 miles long, which is divided by the transverse ridges, or *urdos*, of Timpullo and Assuay into the three great basins of Quito, Ambato, and Cuenca, which are again subdivided by inferior ridges into irregular sections. The eastern Cordillera attains in several of its summits a height of more than 18,000 feet; the western has only one (Chimborazo) which exceeds 17,500. The Quito plain lies 9500 feet above the sea, Ambato 8500, and Cuenca 7800: the last two are comparatively barren and melancholy, while the first, though so much the loftiest of the three, is clothed with luxuriant vegetation. The altitude of the Timpullo or Chisinche ridge, stretching across from Cotopaxi to Iliniza, is 11,500 feet, and that of the Assuay ridge about 13,500. Both the western and eastern slopes of the chain are marked by magnificent valleys of erosion; the former, which contains at least six successive terraces, has an average gradient of 275 feet per mile, while that of the latter is only 125. Granitic, gneissoid, and schistose rocks are the main materials of the gigantic pile; the summits are capped with trachyte and porphyry, and the sides are strewn with immense beds of gravel and volcanic debris. Nowhere in the whole Andean system do the individual mountains attain so magnificent a development as in the Ecuadorian section. Around the valley of Quito alone there are twenty noble volcanic summits, presenting a beautiful variety of form,—here a perfect and there a truncated cone, there a jagged and blasted crest, and there again a smooth and snow-covered dome.

In the Eastern Cordillera the following are capped with perpetual snow—Cayambi, Antisana, Cotopaxi, Llanganati, Sincholagua, Sangai, Sara-ureu, Tunguragua, Collanes, and Assuay; in the Western—Chimborazo, Iliniza, Casalagua, Cotacachi, Pichincha, Corazon, Atacazo, Chiles, Cambarazo, Yana-ureu, and Qulindaña. Imbabura may either be assigned to the eastern range, or perhaps, more properly regarded as the common point of junction. It is situated at the northern end of the great central valley, attains a height of 15,029 feet, and is remarkable for its vast eruptions of mud and water, the most extensive of which took place in 1691. The name, equivalent to the "fish-producing," from *imla*, fish, and *bura*, mother, is supposed to refer to the quantities of *Pimelodus cyclopterus* said to have been contained in its discharges—a phenomenon, however, which has been called in question by Wagner, after a searching investigation into the origin of the report. Cayambi (or by mistake, Cayamburo) is situated exactly on the equator, and is thus distinguished, as Humboldt observes, from every other snow-capped mountain in the world. It is the loftiest summit in the eastern Cordillera, and spreads out at the base over a very extensive area. Antisana rises with a double dome to the height of 18,880 feet, and presents the proof of its former activity in its magnificent lava-streams, of which one, according to Orton, is ten miles long and five hundred feet deep. It may now be classed with the *apagados*, though Humboldt saw smoke issuing in 1802. On the side is the famous *tambo* of Antisana at a height of 13,300 feet above the sea. To the next two peaks—Sincholagua and Rumiñagui, respectively 16,360 and 15,603 feet in height—comparatively little attention has been paid, perhaps from the rivalry of their southern neighbour Cotopaxi. This magnificent mountain has already been briefly described (vol. vi. p. 480). It is the loftiest active volcano in the world. The slope, according to Orton, is 30°, according to Wagner 29°, the north-western side being very slightly steeper than the south-eastern. The apical angle is 122° 30'. On the east it is covered with snow, but on the west it is usually kept bare by the action of the trade winds. Its crater, estimated by Wagner as less than that of Mount Etna, is bordered by a band of trachytic rock, forming a black coronet above the white. On the southern slope, at a height of 15,059 feet, a small

cone of porphyritic andesite, called *el Picacho*, the beak, or *Cabeza del Inca*, the Inca's head, lifts its bare cliffs for above a thousand feet, and from its general appearance gives some show of reason to the tradition which regards it as the original summit of the mountain blown off at the first eruption in 1532. The present summit is usually enveloped in clouds; and even in the clearest month of the year it becomes visible only for eight or ten days. "On the Tacunga plateau," says Wagner (*N. Reisen in trop. Amerika*, p. 514), "at a height of 8000 Paris feet the prevailing direction of the wind is meridional, usually from the south in the morning, and frequently from the north in the evening, but over the summit of Cotopaxi, at a height of 18,000 feet, the north-west wind always prevails throughout the day. The gradually-widening volcanic cloud continually takes a south-eastern direction over the rim of the crater; at a height, however, of about 21,000 feet, it suddenly turns to the north-west, and maintains that direction till it reaches a height of at least 28,000 feet. There are thus from the foot of the volcano to the highest level attained by its smoke-cloud three quite distinct regular currents of wind."

The principal product of the Cotopaxi eruptions is pumice stone; and the flanks of the mountain are covered with deep beds of this material mingled with trachytic rocks. In the vicinity fragments of obsidian are found in great profusion. Llanganati or Cerro Hermoso has been little visited except by natives in search of the golden treasures of the Incas believed to be hid in one of its lakes; and even their curiosity was quenched by the mysterious fate of Padre Longo. Its height is 17,843 feet, and it is said by Villavicencio to contain large quantities of pyrites. In regularity of structure the cone-shaped summit of Tunguragua is similar to Cotopaxi. It attains an altitude of 16,685 feet above the Pacific, and, inasmuch as it rises directly from a plain only 5700 feet above the sea, and is connected with the Cordillera only by a *cuchilla* or "knife-edge" from its southern side, it has a much greater apparent elevation than many a mountain that really overtops it. Its slope is 38°. A catarnet fed by the snows on the summit descends 1500 feet in three leaps; and an enormous basaltic lava-stream, black and smooth and barren as when first it cooled, may be traced in a north-east direction across the channel of many a chafing torrent. The most notable eruption was in 1777. Whether the mountain is now to be classed with the *apagadas* appears doubtful. In 1832 Dr Terry reported that smoke was almost always ascending from the top; Spruce saw smoke issuing from the western side in 1857; two years later Wagner could find no trace of activity though he ascended several times to the snow-line, but since that date Prof. Orton, on the authority of Dr Taylor of Riobamba, reports a continual fuliginous discharge. El Altar is of very irregular shape, consisting of eight snow-clad peaks, the highest of which is 17,735 feet in height. According to an account accepted by Humboldt, there existed at the time of his visit an ancient Quichua manuscript with a description of a terrific catastrophe by which Capac-ureu, the "Chief Mountain"—for so the natives call El Altar—was blown into its present picturesque confusion, and lost the rank it had previously held of the loftiest summit in all the Andes; but more modern inquiries throw the gravest doubt on the trustworthiness of Humboldt's informant, and the manuscript has never been seen by European eyes. The crater, surrounded by a steep and jagged wall of rocks, is remarkable as the bed of the only real glacier known to exist in the Ecuadorian Andes. Sangai, which brings the list of the summits of the Eastern Cordillera to a close, is perhaps the most restless volcano in the world. Since the Spanish conquest three hundred years ago it has been in uninterrupted activity. Small outbursts of lava, accompanied by explosions of steam and reports as of platoon-firing, succeed each other at intervals usually of 10 or 15 minutes, the fiery discharge shooting about 700 or 800 feet above the rim of the crater. From time to time, especially during the rainy season, the symptoms become more violent, the gigantic jet of molten rock leaps up 2000 feet, the explosions are louder and more terrible than the cannonading of armies, and the noise of the thunders amidst the clouds is answered by still more awful *bravidos* from the inferno below. Though of exceptional interest to the physical investigator, not only on account of this perpetual activity, but also on account of its peculiar position in the Andean range, Sangai, by reason of the difficult and dangerous country by which it is surrounded, has been but rarely visited by European travellers. Wisse and Garcia Moreno, and afterwards Schmarda, attempted the ascent. Our knowledge of Chumborazo, the most southern of the predominant summits of the Western Cordillera, has on the other hand received continuous augmentation from explorer after explorer. The "Mountain of Snow"—for such is the meaning of Chumpu-raza, the original form of the name—attains, according to Humboldt, a height of 21,420 feet,¹ and was long regarded as the culminating point of the Andes. The fact that it only makes the plumb-line deviate 7" or 8" shows that it is probably hollow, and there is no doubt the now silent peak was once eloquent with

volcanic thunders. The magnificence of its mass, imposing though it be from almost any point of view, can be fully appreciated only from the Pacific. The summit has never been reached; Humboldt attained to a height of 19,381 in 1802, Bolivar afterwards exceeded this limit; and Bossingault and Hall reached 19,682 in 1831. Access can be obtained either by Chillapillo or by the *arenal*—a stretch of sand and gravel about three miles in length which crosses the N.W. side of the mountain at an elevation of more than 14,000 feet. In ascending by the *arenal* the traveller can reach about 16,219 feet above the sea on horseback, and pursue his difficult path on foot till about 19,693; taking the other route he sleeps at the hacienda about 12,664 feet, may proceed to a height of 15,770 by his mule, and attains his furthest limit at 16,777. To the north of Chimbobrazo, and separated from it only by a narrow valley, Carahuairazo, or, as the Indians call it, Chimbobrazo's Wife, rises to a height of 16,748 feet. It owes its present diminished stature and picturesque profusion of peak and crag to the sudden collapse of its hollow summit in 1699. Quiroto, still further north, is supposed to have suffered a similar fate. It now contains in its hollow summit an extensive lake, which, according to Velasco and Villavicencio, has frequently, and most noticeably in 1740, been covered with flames. The height is calculated at about 13,510 feet. Hunza is a magnificent mountain with two pyramidal peaks, of which the loftiest rises 17,395 feet above the sea. In the 18th century it was trigonometrically measured by the French Academician Bouguer, and Wagner succeeded in reaching within 800 feet of the top, and was only prevented by a sudden storm from completing the ascent. Mules can only be used to a height of 13,200 feet. The geological phenomena furnish no evidence of any volcanic activity either from the summit or the sides. Corazon, so called from its heart-shaped appearance, is equally destitute of a crater. Its summit, 15,796 feet above the sea, has been reached by La Condamine and Bouguer, Humboldt and Bonpland, and José Caldas. Atacazo, about 16,000 feet in height, has nothing very remarkable in its appearance or history. According to Wagner, it has no activity, and from its weather-worn aspect seems of older date than its mightier neighbour Pichincha. The summit of the latter, the "Boiling Mountain," presents three groups of rocky peaks, of which the most westerly, Rucu-Pichincha or Old Pichincha, alone displays volcanic activity. The crater, believed to be the deepest on the face of the globe, consists of a funnel-shaped basin 2500 feet deep, 1500 feet wide at the bottom, and upwards of a mile wide at the mouth. The inner sides rise in some places vertically, in others with an angle of 20°, the exterior of the cone has an angle of 30°. Bouguer and La Condamine reached the brink in 1742; Wisse and Moreno entered the crater in 1844; and Farrand and Orton have descended to the bottom, the latter in 1867. Orton gives a thrilling description of his exploit. He found that the real cone of eruption was an irregular heap 250 feet in height and 800 feet in diameter, containing about seventy vents. The temperature of the vapour within the fumarole was 184°, and water boiled at 189°. There have been five eruptions of Pichincha since the Spanish conquest—in 1539, 1566, 1577, 1587, and 1660. The second covered Quito three feet deep with ashes and stones. The last, happily, broke down the western side of the crater, so that in any future outburst Quito will probably be safe. Since the earthquake of August 1867, the mountain has sent forth dense masses of black smoke, and large quantities of fine sand. Of Cotacachi, a conical summit 16,288 feet high, and Chiles, a truncated cone about 16,200 feet high, comparatively little is known. The latter is situated on the frontiers of Ecuador, and its northern neighbour Cumbal lies in the territory of Colombia.

Rivers.—The surplus waters of the eastern versant in Ecuador all find their way to the great head-stream of the Amazon, those of the western form a large number of independent rivers disembodying in the Pacific. The Napo, which claims the first place, rises in the eastern defiles of Cotopaxi and Sincholagua—the principal source being the Rio del Valle, which traverses the Valle Vicioso. The river is still 1450 feet above the sea-level at the village of Napo, 858 at the mouth of the Coca, 586 at the mouth of the Aguarico, 500 at the mouth of the Curaray, and 385 where it joins the Marañon. The current, as observed by Orton in the month of November, was six miles an hour at Napo; in the course of the next eighty miles the river falls 350 feet, and produces a fine series of rapids; and from Santa Rosa downwards the rate is not less than four miles an hour. The breadth of the stream, which is only 120 feet at Napo, has increased to 1500 feet by the time it reaches Coca, and near the end of its course is little less than a full mile. The junction with the Marañon takes

¹ Roiss and Stübel make it only 20,697 feet

place by several distinct mouths. For some distance beyond the mouth of the Coca the channel is navigable for steam-boats, and the natives proceed in canoes as far as the Cataract del Cando, 3332 feet above the sea-level. The Curaray rises in the Llanganati Cordillera, and flows almost parallel with the Napo till their point of confluence, a distance of 490 miles. The waters are rendered unpalatable by a reddish slime in the lower part of its course, where the current is very gentle. The Aguarico, formed by the union of the Cofanes, San Miguel, and Azuela, which descend from the Pimampiro Cordillera in the northern limits of the country, has a course of about 420 miles. The Coca, rising in the neighbourhood of Cayambi and the Guamani Mountains, receives the Maspa and the Cosanga, flows eastward along the line of the equator as far as $76^{\circ} 10'$ W. long, turns southward, takes a leap of 137 feet, and maintains the same direction till it reaches the Napo rather as a rival than a tributary. The Napo system thus drains a district extending from 1° N. to 3° S. lat. and from $78^{\circ} 10'$ to $73^{\circ} 50'$ W. long. The only other Ecuadorian tributary of the Marañon that has any claim to special notice is the Pastassa. Instead of having its head-waters in the eastern slopes of the Eastern Cordillera, as is the case with most if not all of the rivers already described, it rises in the central plateau, within the shadow of Cotopaxi, forces its way through the range to the north of Tunguragua, and flows south-eastwards past the roots of Sangai, augmented from stage to stage by the numerous torrents that are fed by the eternal snows. It bears the name of Patate till its junction with the Chambo in the neighbourhood of Baños, and is not recognized as the Pastassa above the Agoyan falls. As early as 1741 it was navigated without difficulty by Don Pedro Maldonado; and it is believed that it would afford a passage for steamboats for a distance of 314 miles. Mr Simson, one of the most recent explorers of eastern Ecuador, gives a graphic account of the terrific floods to which its mountain tributaries, and more especially the Topo, are subject. The rise of the waters is sometimes so sudden, and their fury so irresistible, that trading parties are imprisoned for weeks in the narrow strip of land between one torrent and the next; and the whole country is traversed in the line of the currents by long ridges, or *cuchillas*, produced by the disintegration and removal of all the intermediate tracts. The same, indeed, holds true more or less of the whole eastern slope of the mountains and of the upper sections of all the rivers. On the western versant of the Ecuadorian Andes there are three river systems of considerable size—the Mira, the Esmeraldas, and the Guayaquil. The first has its head-waters—the Rioblanco, the Pisco, and the Pantal—in the vicinity of Imbabura, breaks through the Western Cordillera, receives from the left the San Pedro, Paramba, Cachiya, Chachavi, Canumbi, and from the right the San Juan, Gualpi, and Nnpe, and empties itself by several mouths into the Pacific near the island of Tmaco. The second, which is the largest of the three, collects its abundant waters from Cotopaxi and Sincholagua, the transverse ridge of Timpullo or Chisinche, Iliniza, Pichincha, and Cayambi. The Cotopaxi tributary, known as the Rio Pedregal, forms three beautiful cascades, the highest of which is about 220 feet. To the Guayaquil system belong the Daule, the Babahoyo, and the Yaguachi, with their numerous tributaries,—the Daule rising in the Sandomo ridge, the Babahoyo in the slopes of the Western Cordillera, and the Yaguachi in the skirts of Chimborazo. They are all navigable for some distance inland by steamer, and are of great importance in connection with the transport of native produce to the port of Guayaquil. Floods are usual in the rainy season, and vast stretches of country are laid under water. In the Daule the tide is felt at Candelaria,

25 miles inland. Along the coast, between the mouth of the Esmeraldas and the Gulf of Guayaquil, a large number of streams find their way to the sea; but as they all have their sources in the comparatively insignificant line of hills that runs north and south about 25 or 30 miles inland, they are themselves comparatively insignificant.

Lakes.—While Ecuador can boast of nothing worthy of the name of an inland sea, it possesses a large number of lakes, either lying in the laps and extinct craters of the Andes, or formed in the lowlands by the overflowings of its rivers. To the former class belong San Pablo, at the foot of Imbabura, 5 miles in circumference; Cuy-cocha, on the south-east skirt of Cotacachi, 10,200 feet above the sea, and thus one of the highest lakes in the world; Yaguar-cocha, or "Lake of Blood," not far from Ibarra; Quiroto, about 4600 feet in diameter; Coita, to the east of Riobamba, with a powerful whirlpool in the centre, and Colay, to the south of Riobamba, which exhales gases poisonous enough to stupefy the birds that attempt to cross, and thus helps to fill the larder of the Indians in its neighbourhood. The largest specimens of the second class lie along the Napo. Thermal springs are mentioned in numerous localities,—as at Belermos and San Pedro del Tingo, north-east of Quito; at Cachillacta, in the district of Nancag; in the skirts of Rumiagui; at Timbngpoyo, near Tacunga; on the slopes of Chimborazo; and at Baños, near the foot of Tunguragua.

Minerals.—Ecuador is less rich in minerals, especially in the precious metals, than any other of the South American states. Silver, gold, iron, mercury, lead, tin, zinc, copper, antimony, manganese, alum, sulphur, and salt are all said to be found; but very few of these exist in sufficient quantity to affect the destinies of national industry. Gold mixed with silver has long been obtained in the neighbourhood of Zarume, in the province of Loja, and it is gathered by the Indians from the river beds in the Napo and Canelos territory, and more particularly from the Bobonaza. The gold of the Canelos is about 22 carats fine, and that of the Napo 20. The town of Azogues derives its name from its prolific quicksilver mines; and similar deposits are worked within the city of Loja. In the pueblo of Simiatug, to the south-east of Riobamba, the natives manufacture salt from brine springs, and export it under the name of *sal de Tomavela*; the produce of Salinas—a name which tells its own tale—in Imbabura, finds its way to Colombia. Coal of good quality occurs in the province of Cuenca and also on the banks of the Napo near Pucarcun, the "Red Mountain." Marble, alabaster, gypsum, slate, and other industrial rocks are obtained in various localities; beautiful rock crystal is worked at Chongon, in the province of Guayaquil; and in the coast districts there exist considerable deposits of asphalt.

Climate.—The description already given of the position and vertical arrangement of the country implies the main characteristics of Ecuadorian climate. The snow-line varies considerably in the different seasons of the year, as well as according to the form and situation of the individual mountain. Wagner found it in May on Cotacachi, 15,788 feet high; on Guagua-Pichincha in June, 15,741; on Mozc-Pichincha in May, 15,762; on Iliniza in December, 15,494; on Carahnirazo in January, 15,858; on Tunguragua in February, 15,613; and on El-Altar in February, 15,854. The greatest difference, according to his observations, existed between the south side of Cotopaxi (15,279 feet) and the north side of Chimborazo (15,914). This elevation of the snow-line—so great when compared with its European position—of course renders possible the existence of vegetable and animal life at a correspondingly great height. While St Bernard's, the highest point of permanent habitation in Europe, is only 8377 feet above the sea, over the

of the towns and villages of the central plateaux from Ibarra to Cuenca lie between 8500 and 9500 feet; many of the huts of the cattlemen are at a height of from 11,500 to 12,800; and the loftiest of these, at Cunayaco, on the north side of Chimborazo, in $1^{\circ} 28' S.$ lat., stands no less than 13,396 above the sea. The temperature of these upland districts is of course comparatively low. "At Quito," says Professor Orton, "it is never either spring, summer, or autumn, but each day is a combination of all three." The thermometric mean is $58^{\circ} 8'$; the range in the 24 hours about 10° , the annual maximum 70° , and the annual minimum 45° . In the lower coast-region the tropical position of the country is the main factor, and accordingly at Guayaquil we find the thermometric mean is 83° , and during the rainy season the oppressive and pestiferous air "reminds the geologist of the steaming atmosphere of the Carboniferous period." The rainy season, or *invierno*, in Ecuador continues from December to May, with a short period of dry weather called the *veranillo* shortly after the December solstice. The rest of the year forms the *verano*, or summer, which, however, is in like manner interrupted by a little rainy season called the *inviernillo*, or Cordonazo de San Francisco, after the September equinox. The mean annual rainfall at Quito is 70 inches. In the coast region the two seasons are not very distinctly marked: in the invierno the sky is sometimes perfectly cloudless, while during the verano there occasionally falls a continuous drizzle called *garúa*. According to Villavicencio, a gradual diminution of rain has been observed in this district of irregular seasons, and he predicts the assimilation of its climate to that of the rainless coasts of Peru. On the eastern side of the Andes, on the other hand, rain occurs almost at any time of the year, and almost every morning the woods are watered with the gentle showers of the *rocío*. During the verano the Cordilleras and *mesas* are visited by violent hail-storms, and winds of almost incredible force sweep across the wintry scene. In its relation to human health the climate of the upland region is interesting. Goitre is common; and it is found necessary to maintain three large hospitals for lepers. Tubercular disease of the lungs, on the contrary, is said to be completely unknown 8000 feet above the sea, while it is one of the most frequent of diseases in the coast districts of Tropical America. The effects on the human organism of the ascension of the loftier summits are very variously described, owing doubtless to individual differences of constitution. One thing seems established,—that the pugnacious instincts both of men and the lower animals are greatly weakened.

Botany.—The flora of the Quitoman plateau has been well explored by various European botanists, and more especially by Dr Jameson of the university of Quito;¹ that of the western slopes and lowlands is less perfectly ascertained; and that of the richly-wooded country stretching eastward from the Andes is still in great part undescribed. From the coast of the Pacific upwards to a height of about 3000 or 4000 feet, the vegetation is distinctively tropical, including among its economical species the banana, the sweet potato, rice, maize, the bread-fruit tree, indigo, cotton, cocon, the yam, the maudioc, and the sugar cane. Most of these become rare above 3000 feet, but a few, like the sugar cane, are cultivated as high as 8000. Few parts of the world can vie in richness of vegetation with the alluvial valley of Guayaquil, which in the matter of fruit trees alone produces cocon-nuts, pine-apples, pomegranates, shaddocks, oranges, lemons, apricots, chirimoyas, pultas, granadillas, tunas, mangos, paeys, and many others of less importance. Between 6000 and 10,000 feet above the sea the European cereals are successfully cultivated,

along with the chick-pea, the broad-bean, the cabbage, the quinoa (*Chenopodium Quinoa*), potatoes, *Oxalis*, *Basella*, and *Tropæolum*. Wheat will not form the ear lower than at 4500 feet, or ripen higher than at 10,500; but barley and rye can be grown at a still greater elevation. The oak, the elm, the ash, and the beech never descend lower than to 5500 feet, and are seldom found higher than 9200. Further up, the larger forest trees, except the pine, begin to disappear; but the *Escallonia myrtilloides* is met with at an elevation of 13,000; and the shrubby *Befarias* ascend 400 or 500 feet higher. In the treeless region that lies between 11,600 and 13,800, or in other places between 12,000 and 14,000 feet, the similarity of the vegetation to that of the corresponding European region is, according to Wagner, especially striking. In the paramos of Chimborazo, Pichincha, Iliniza, &c., the relation of characteristic genera to those identical with genera in the Alpine flora of Europe is as 5 to 4; and the botanist might almost suppose himself in the Upper Engadine. As the region of cryptogams does not properly begin till about 17,000 feet on Cayambi and Chimborazo, most of the summits of the Cordilleras, failing, as they do, to reach this elevation, yield a considerable harvest of phanerogamous plants. Boussingault discovered a species of saxifrage (*Saxifraga Boussingaultii*) at a height of nearly 16,000 feet on Chimborazo, and Wagner found the trachytic rocks of Pichincha, Iliniza, and other peaks, far above the snow line, covered in many places with the gonda-plant, or *Calceitum nivale*, H. The species in these upper regions are frequently very remarkable, and a large number of strangely-modified forms have been collected from the craters of the volcanoes.

In its forest-lands alone Ecuador possesses almost inestimable resources. Seven different species of cinchona are known to exist within its borders; the *Ceroxylon andicola* and many lesser species of palm abound on both sides of the Cordilleras; and redwood, Brazil wood, palo de cruz, guaiacum or holy wood, ebony, cedar, and aguana are a few of the more usual timber trees. In the dripping forests of the west grows the *sindi-caspi*, which forms excellent fuel even in its moistest condition. Copal, dragon's blood, india-rubber, storax, and several valuable dye-stuffs are obtained from indigenous plants. The cabaya or agave, the chambiri palm, &c., yield textile fibres; and the leaves of the toquilla (*Carludovica palmata*) and the mocora, a cocon-nut-like tree, furnish material for the well-known hats.

Zoology.—The fauna of Ecuador does not present a great variety among the mammalia; but the birds, and still more the insects, are very numerous. The jaguar, the puma, the onnce, and the ocelot are the chief representatives of the cat tribe; monkeys of various species are common; the four characteristic animals of the Andean range, the llama, the guanaco, the vicuña, and the alpaca, are fairly abundant; large herds and flocks of European cattle and sheep are found in the rich pasture of the paramos; and horses, asses, and mules are reared in sufficient numbers to be articles of export. Few rivers are more densely peopled with alligators than the Guayaquil and Esmeraldas; and several of the largest species of snakes are natives of the warmer regions of the country, though in the Cordilleras and plateaus the reptilia are very rare. The condor, the turkey-buzzard, the gallinazo, the crane, and the pelican are among the larger birds; and ducks, pheasants, and partridges are not uncommon. Of the lesser birds perhaps none appears in such number and such striking variety of form and colour as the humming bird, which is found frequently at a great height on the mountains. The flautero or flute-bird is especially noticeable for the artistic character of his song. That the entomologist finds a rich harvest of coleopterous insects in the low countries is in keeping

¹ See his *Synopsis Plantarum Equatoriensum*, 2 vols.

with what might be expected; butterflies are so numerous in some parts as even to surprise the veteran collector; and in certain favoured regions, mosquitoes, sand-flies, and the equally troublesome pioms seem nearly as prolific as their ancient congeners in Egypt. The silkworm has been successfully introduced, but bee-keeping is as yet practically unknown. The ichthyology of Ecuador, and more particularly that of the rivers, of the Amazon system, is very partially ascertained; but the species of the two versants seem to be quite distinct. According to Wagner's investigations the distribution is mainly vertical, and to the N. of Chimborazo alpine forms go as high as 13,400 Paris feet; the forms of the lower region (or under 1000 feet), are closely connected with those of Brazil and Guiana; more peculiar genera appear in the middle region, (from 1000 to 7000 feet), and the upper region is exclusively occupied by characteristic and frequently very strangely-shaped genera; the number of species is comparatively small, and that of individuals great only in the lower parts of the rivers.

Produce and Industries.—The principal article of foreign export is cocoa, of which two kinds especially are distinguished in the market—the fine “up-river” quality and the so-called Machala quality Spain is the greatest purchaser, then England, Germany, and Peru and Chili. In 1874 the total quantity that left the country was 250,216 quintals, valued at 2,752,381 pesos, or, taking the peso as equal to 4s 2d., £573,412. The collection of india-rubber is becoming an important trade; and pupils trained at the Government expense have been sent into the various provinces to superintend the introduction of indigo cultivation. Cotton, not proving a profitable investment, is being somewhat neglected: the export in 1874 was only 440,091 lb, valued at 35,208 pesos. The other articles, arranged in the order of importance, were—coffee, 10,652 lbs, at 245,014 pesos; Cinchona bark, 981,132, at 196,226 pesos; vegetable ivory, 7,148,192 lb, at 142,963 pesos; straw hats, 7600 dozen, at 91,200 pesos; sole-leather, 19,744 pieces, at 88,848 pesos; dried skins to the amount of 43,115 pesos; bamboos to the amount of 23,002; and small quantities of sarsaparilla, algarroba, tamarinds, tobacco, pita, orchilla, rice, mats, and saibo-wool. A bank of issue and deposit, called the Bank of Ecuador, with a capital of a million dollars, was established in 1868.

Details of Political and Social Condition.—The main basis of the Ecuadorian constitution dates from 1843, but several important modifications have been introduced at various periods. The executive power is vested in a responsible president elected by a majority of votes among a body of 900 electors appointed by popular suffrage. He has no right of veto, and cannot interfere in any way with the sitting of the congress. Besides a vice-president, who is elected in the same way as the president, and, according to the decree of 1869, discharges the functions of home secretary, the cabinet comprises a minister of war and marine, a minister of finance, the president of the supreme court, and a prominent member of the clerical body. The legislative assembly or congress is divided into two houses, the upper consisting of sixteen senators, the lower of thirty deputies elected by popular suffrage. The judicial system comprises a supreme court at Quito, three upper courts, provincial courts, municipal courts presided over by the alcaldes, and parochial courts. Jury trial is employed in criminal cases, but many districts are very evidently too ignorant for the satisfactory working of the method. A governor-general is appointed for Guayaquil and Quito respectively. Slavery was abolished in 1854 all races and classes are equal in the eyes of the law, and there are no hereditary distinctions of rank or title. The military force numbers only about 1200 men, and the marine consists of three small steamers. The finances have long been in a rotten condition, and trustworthy information is of difficult attainment. The public revenue in 1873 was stated at 3,650,510 dollars or piastres (about £780,102); and the expenditure at 3,985,560 dollars (about £787,112). In 1872 the receipts were thus divided—Customs, 1,707,403 piastres; duty on tobacco, 19,034; duty on alcohol, 111,420; salt monopoly, 312,785; gunpowder monopoly, 30,477; stamped paper, 114,395; income-tax, 67,451; duty on sale of land, 216,110; tithes, 371,611; mont-de-piété, 1159; post-office, 96,280; national property, 52,866; miscellaneous, 512,297—total, 3,613,536. In

1857 the national debt amounted to 16,370,000 piastres (or £3,274,000), of which £1,824,000 was the English loan contracted in 1855.

Artificial means of communication are still for the most Com part in a very primitive condition, though few countries have catio so little reason to be content with their natural highways by land or water. Many of the roads, even between important centres of population, are mere mule-tracks, altogether impassable in bad weather it may be for weeks or months at a time; while the violent torrents which have so frequently to be crossed often present nothing better than more or less elaborate bridges of rope, similar to the *ghuler* or *zampur* of the Kashmirians. The simplest of these is the *taravita*, consisting of a single tight rope, with or without a travelling rope by which the passenger or his luggage may be hauled across; the most complex is the *chimba-chaca*, a rude prototype of the regular suspension bridge, constructed of four or five ropes of agave-root fibre, supporting transverse layers of bamboos. The best are hazardous to all except a practised foot, and they go out of repair in a few years. Since the middle of the century something has been done to improve this state of affairs; and a very great deal more has always been about to be done. According to Moreno's address to congress in 1873, Ecuador had at that time 30 miles of railway, nearly 200 miles of cart-road with substantial bridges, and about 250 miles of roads fit for the ordinary mule-traffic of the country. Wheeled conveyances are almost unknown, especially in the inland districts, the transport of goods of every description being effected by porters or mules. The first carriage was introduced into Quito in 1859, and the owner had to pay a tax for his innovation.

With the partial exception of such rude forms of belief as still Reli linger among the semi-civilized Indians, the only religion professed by the Ecuadorian populations is the Roman Catholic. Nowhere in modern times have Jesuits and priests had it more their own way. Even in 1876 Dr Borrero, the “liberal” president, thought it expedient to declare that he would protect the religion of his fathers, which he believed “had not an enemy in all Ecuador.” Two years before, in spite of the extremely depressed state of the finances, ten per cent. of the part of the church revenue belonging to the state was assigned to the Pope as an annual offering. The oath of a Protestant has no value in a court of justice; and it was regarded as an extraordinary stretch of liberality to allow the formation of a Protestant burial-ground at Quito in 1867. Monkish orders that lost their influence in Europe centuries ago still flourish in Quito—Trinitarians, Dominicans, Augustinians, Brown Franciscans, Black Franciscans, Lazarists, &c. According to Villavicencio, the number of the regular clergy at the time he wrote was 415, of the secular clergy 524, and of nuns 391. Quito is the seat of an archbishop; and there are bishoprics for Cuenca, Loja, Ibarra, Riobamba, Guayaquil, and Manabí.

Education has hitherto been left in the hands of the clergy, and Eln primary education is consequently in a very defective condition. There has long been a university at Quito with about a dozen professors and nearly 300 students; and in 1875 the Ecuador academy was instituted in the city in accordance with the decree of the Spanish academy of Madrid. There are colleges in several of the larger towns, and nearly 600 schools exist throughout the country. The normal school at Guayaquil is open to Indian children.

For administrative purposes the country is divided into eleven Prov provinces—Azuay, with 149,103 of a population in 1871; Chimborazo, 110,860; Pichincha, 102,281; Guayas, 87,427; Imbabura, 77,379; Leon, 76,140; Tungurahua, 73,143; Los Rios, 61,922; Loja, 60,784; Manabí, 59,098; Esmeraldas, 8000. Besides the capital, whose inhabitants are variously estimated from 35,000 to 80,000, the largest cities are—Guayaquil, from 20,000 to 25,000; Tacunga, from 16,000 to 20,000; Cuenca, about 25,000; Riobamba and Ibarra, both perhaps about 16,000; Ambato, about 10,000; Otavalo, about 8000; Guaranda, 8000; and Cotacachi, 4000.

Antiquities.—Throughout Ecuador there are still considerable Anti remains of the architectural and artistic skill of the ante-European quiti period. At Cañar, to the north-east of Cuenca, stands the Inca-pirca, a circular rampart of finely hewn stone, inclosing an open area with a roofless but well-preserved building in the centre; not far off is the Inca-chungana, a very much smaller inclosure, probably the remains of a pavilion; and in the same neighbourhood the image of the sun and a small cabinet are carved on the face of a rock called Inti-huacú. On one of the hills running from Pichincha to the Esmeraldas there are remains at Paltatamba of a temple and a conical tower, the buttresses of a bridge composed of stone and bitumen, portions of a great causeway, and numerous tombs from which mummies and plates of silver have been obtained. At Hantuntaqui similar sepulchral mounds, called *tolas*, may be seen, as well as traces of military structures. On the plain of Callo, near Cotopaxi, at a height of 8658 feet, the ruins of an Incarial palace, Pachasala, are utilized by the *hacienda*; and a conical hill at its side is supposed to be of artificial construction. The remains of another fortress and palace are preserved at Pomallacta, and in the

neighbouring pueblo of Achupallas an ancient temple of the sun now serves as parish church.

History.—The territory of the present republic of Ecuador, when first it becomes dimly visible in the grey dawn of American history, appears to be inhabited by upwards of fifty independent tribes, among which the Quittus seem to hold the most important position. About 230 A.D. a foreign tribe is said to have forced their way inland up the valley of the Esmeraldas, and the kingdom which they founded at Quito lasted for about 1200 years, and was gradually extended, both by war and alliance, over many of the neighbouring dominions. In 1460, during the reign of the fourteenth *Caran Shyri*, or king of the Caran nation, Huacopco Duchisela, the conquest of Quito was undertaken by Tupac Yupanqui, the Inca of Peru; and his ambitious schemes were, not long after his death, successfully carried out by his son Huaina-Capac, who inflicted a decisive defeat on the Quitomans in the battle of Hatuntaqui, and secured his position by marrying Paella, the daughter of the late Shyri. By his will the conqueror left the kingdom of Quito to Atahualpa, his son by this alliance; while the Peruvian throne was assigned to Huascar, an elder son by his Peruvian consort. War soon broke out between the two kingdoms, owing to Huascar's pretensions to supremacy over his brother; but it ended in the defeat and imprisonment of the usurper, and the establishment of Atahualpa as master both of Quito and Cuzco. The fortunate monarch, however, had not long to enjoy his success; for Pizarro and his Spaniards were already at the door, and by 1533 the fate of the country was sealed. As soon as the confusions and rivalries of the first occupation were suppressed, the recent kingdom of Quito was made a presidency of the Spanish vice-royalty of Peru, and no change of importance took place till 1710. In that year it was attached to the viceroyalty of Santa Fé; but it was restored to Peru in 1722. When, towards the close of the century, the desire for independence began to manifest itself throughout the Spanish colonies of South America, Quito did not remain altogether indifferent. The Quitomau doctor Eugenio Espejo, and his fellow-citizen Don Juan Pio Montufar, entered into hearty co-operation with Nariño and Zea, the leaders of the revolutionary movement at Santa Fé; and it was at Espejo's suggestion that the political association called the *Escuela de Concordia* was instituted at Quito. It was not till 1809, however, that the Quitonians made a real attempt to throw off the Spanish yoke; and both on that occasion and in 1812 the royal general succeeded in crushing the insurrection. In 1820 the people of Guayaquil took up the cry of liberty; and in spite of several defeats they continued the contest, till at length, under Antonio José de Sucre, who had been sent to their assistance by Bolívar, and reinforced by a Peruvian contingent under Andres de Santa Cruz, they gained a complete victory on May 22, 1822, in a battle fought on the side of Mount Pichincha, at a height of 10,200 feet above the sea. Two days after, the Spanish president of Quito, Don Melchor de Aymeric, capitulated, and the independence of the country was secured. A political union was at once effected with New Granada and Venezuela on the basis of the republican constitution instituted at Cuenca in July 1821,—the triple confederation taking the name of Colombia.

A disagreement with Peru in 1828 resulted in the invasion of Ecuador and the temporary occupation of Cuenca and Guayaquil by Peruvian forces; but peace was restored in the following year after the Ecuadorian victory at Tarqui. In the early part of 1830 a separation was effected from the Colombian federation, and the country was proclaimed an independent republic. General Juan José Flores was the first president, and in spite of many difficulties, both domestic and foreign, he managed to maintain a powerful position in the state for about 15 years. Succeeded in 1835 by Vicente Rocafuerte, he regained the presidency in 1839, and was elected for the third time in 1843; but shortly afterwards he accepted the title of generalissimo and a sum of 20,000 pesos, and left the country to his rivals. One of the most important measures of his second presidency was the establishment of peace and friendship with Spain. Roca, who next attained to power, effected a temporary settlement with Colombia, concluded a convention with England against the slave trade, and made a commercial treaty with Belgium. Diego Noboa, elected in 1850 after a period of great confusion, recalled the Jesuits, produced a rupture with New Granada by receiving conservative refugees, and thus brought about his own deposition and exile. The democratic Urbina now became practically dictator, and as the attempt of Flores to reinstate Noboa proved a total failure, he was quickly succeeded in 1856 by General Francisco Robles, who, among other progressive measures, secured the adoption of the French system of coinage, weights, and measures. He abdicated in 1859 and left the country, after refusing to ratify the treaty with Peru, by which the defender of Guayaquil had obtained the raising of the siege. Dr Gabriel García Moreno, professor of chemistry, the recognized leader of the conservative party at Quito, was ultimately elected by the national convention of 1861. Distrust in his policy, however, was excited by the publication of some of his private correspondence, in which he spoke favourably of a French protectorate, and the army which

he sent under Flores to resist the encroachments of Mosquera, the president of New Granada, was completely routed. His first resignation in 1864 was refused; but the despotic acts by which he sought to establish a dictatorship only embittered his opponents, and in Sept. 1865 he retired from office. While he had endeavoured to develop the material resources of the country, he had at the same time introduced retrograde measures in regard to religion and education. The principal event in the short presidency of his successor, Geronimo Carrion (May 1865–Nov. 1867), was the alliance with Chili and Peru against Spain, and the banishment of all Spanish subjects. Several important changes were made by congress in the period between his resignation and the election of Xavier Espinosa, Jan. 1868: the power of the president to imprison persons regarded as dangerous to public order was annulled, and the immediate naturalization of Bolivians, Chilians, Peruvians, and Colombians was authorized. Espinosa had hardly entered on his office when, in August 1868, the country was visited by an earthquake, in which 30,000 people are said to have perished throughout South America. The public buildings of Quito were laid in ruins, and Ibarra, Otavalo, Cotacachi, and several other towns were completely destroyed. Next year a revolution at Quito, under Moreno, brought Espinosa's presidency to a close; and though the national convention appointed Carvajal to the vacant office, Moreno succeeded in securing his own election in 1870 for a term of six years. His policy had undergone no alteration since 1865: the same persistent endeavour was made to establish a religious despotism, in which the supremacy of the president should be subordinate only to the higher supremacy of the clergy. The tyranny, however, came to a sudden end in August 14th 1875, when the president was assassinated in Quito, by three of his private enemies. The consequent election resulted in the appointment of Dr Borrero, who, in his address to congress, December 1876, promised "to maintain, during the tenure of the responsible office to which he had never aspired, full political liberty and the freedom of the press." An insurrection headed by Ventemilla, the military commandant of Guayaquil, had already broken out, and on the 14th December the Government forces under Aparicio were completely routed at Galte.

EDAM, a town of the Netherlands, in the province of North Holland and arrondissement of Hoorn, about 11 miles north-east of Amsterdam, and hardly a mile from the present limits of the Zuider Zee, at the junction of two branch canals. It has a fine town-house, an exchange, and a fish-market, and one of its two Reformed churches is adorned with stained glass, and ranks among the most beautiful buildings of the kind in the province. Ship-building, rope-spinning, and salt-boiling are carried on, and the place gives its name to a well-known description of "sweet-milk" cheese—*Zoetemelks Kaas*. It was at Edam that nearly the whole of Admiral De Ruyter's fleet was constructed. Population of the commune in 1869, 5152, and of the town 3356.

EDDA, the original signification of which is "great-grandmother," is the title given to two very remarkable collections of old Icelandic literature. Of these only one bears that title from antiquity; the other is named *Edda* by a comparatively modern misnomer. The only work known by this name to the ancients was the miscellaneous group of writings attributed to Snorri Sturluson (1178–1241), a scholar of Jon Löftsson, and the greatest name in old Scandinavian literature. It is believed that the *Edda*, as he left it, was completed about 1222. Whether he gave this name to the work is doubtful; the title first occurs in the Upsala Codex, transcribed about fifty years after his death. The collection of Snorri is now known as the *Prose*

or *Younger Edda*, the title of the *Elder Edda* being given to a book of ancient mythological poems, discovered by the Icelandic bishop of Skálholt, Brynjulf Sveinsson, in 1643, and erroneously named by him the *Edda of Sæmund*.

1. The Prose *Edda*, properly known as *Edda Snorra Sturlusonar*, was arranged and modified by Snorri, but actually composed, as has been conjectured, between the years 1140 and 1160. It is divided into five parts, the Preface or *Formáli*, *Gylfaginning*, *Bragaræður*, *Skáldskaparmál*, and *Háttatal*. The preface bears a very modern character, and simply gives a history of the world from Adam and Eve, in accordance with the Christian tradition. *Gylfaginning*, or the Delusion of Gylfi, on the other hand, is the most precious compendium which we possess of the mythological system of the ancient inhabitants of Scandinavia. Commencing with the adventures of a mythical king Gylfi and the giantess Gefion, and the miraculous formation of the island of Zealand, it tells us that the Æsir, led by Odin, invaded Svithjod or Sweden, the land of Gylfi, and settled there. It is from the *Ynglingasaga* and from the *Gylfaginning* that we gain all the information we possess about the conquering deities or heroes who set their stamp upon the religion of the North. Advancing from the Black Sea northwards through Russia, and westward through Esthonia, the Æsir seem to have overrun the south lands of Scandinavia, not as a horde but as an immigrant aristocracy. The Eddaic version, however, of the history of the gods is not so circumstantial as that in the *Ynglingasaga*, it is, on the other hand, distinguished by an exquisite simplicity and archaic force of style, which give an entirely classical character to its mythical legends of Odin and of Loki. The *Gylfaginning* is written in prose, with brief poetic insertions. The *Bragaræður*, or sayings of Bragi, are further legends of the deities, attributed to Bragi, the god of poetry, or to a poet of the same name. The *Skáldskaparmál*, or Art of Poetry, commonly called *Skálda*, contains the instructions given by Bragi to Ægir, and consists of the rules and theories of ancient verse, exemplified in copious extracts from Eyvindr Skáldaspillir and other eminent Icelandic poets. The word *Skáldskapr* refers to the form rather than the substance of verse, and this treatise is almost solely technical in character. It is by far the largest of the sections of the *Edda* of Snorri, and comprises not only extracts but some long poems, notably the *Thorsdrapa* of Eilífr Guðrúnarson and the *Hauslaug* of Thjóðólfr. The fifth section of the *Edda*, the *Háttatal*, or Number of Metres, is a running technical commentary on the text of Snorri's three poems written in honour of Hakon, king of Norway. Affixed to some MS of the *Younger Edda* are a list of poets, and a number of philological treatises and grammatical studies. These belong, however, to a later period than the life of Snorri Sturluson.

The three oldest MSS of the prose *Edda* all belong to the beginning of the 14th century. The Worm MS. was sent to Ole Worm in 1628, the Codex Regius was discovered by the indefatigable bishop Brynjulf Sveinsson in 1640. The most important, however, of these MSS is the Upsala Codex, an octavo volume written probably about the year 1300. There have been several good editions of the *Edda Snorra Sturlusonar*, of which perhaps the best is that published by the Arno-Magnæan Society in Copenhagen in 1848, in two vols., edited by a group of scholars under the direction of Jón Sigurdsson.

2. The Elder *Edda*, Poetic *Edda*, or *Sæmundar Edda hins froða* was entirely unknown until about 1643, when it came into the hands of Brynjulf Sveinsson, who, puzzled to classify it, gave it the title of *Edda Sæmundi multiscri.* Sæmund Sigfusson, who was thus credited with the collection of these poems, was a scion of the royal house of Norway, and lived from about 1055 to 1132 in Iceland. The poems themselves date in all probability from

the 8th or 9th centuries, and are many of them only fragments of longer heroic chants now otherwise entirely lost. They treat of mythical and religious legends of an early Scandinavian civilization, and are composed in the simplest and most archaic forms of Icelandic verse. The author of no one of them is mentioned. It is evident that they were collected from oral tradition; and the fact that the same story is occasionally repeated, in varied form, and that some of the poems themselves bear internal evidence of being more ancient than others, proves that the present collection is only a gathering made early in the Middle Ages, long after the composition of the pieces, and in no critical spirit. Sophus Bugge, indeed, one of the greatest living authorities, absolutely rejects the name of Sæmund, and is of opinion that the poetic *Edda*, as we at present hold it, dates from about 1210. There is no doubt that it was collected in Iceland, and by an Icelandic.

The most remarkable and the most ancient of the poems in this priceless collection is that with which it commences, the *Völuspá*, or Prophecy of the Volva or Sibyl. In this chant we listen to an inspired prophetess, "seated on her high seat, and addressing Odin, while the gods listen to her words." She sings of the world before the gods were made, of the coming and the meeting of the Æsir, of the origin of the giants, dwarfs, and men, of the happy beginning of all things, and the sad ending that shall be in the chaos of Ragnarök. The latter part of the poem is understood to be a kind of necromancy,—according to Vigfusson, "the raising of a dead volva;" but the mystical language of the whole, its abrupt transitions and terse condensations, and above all the extinct and mysterious cosmology, an acquaintance with which it presupposes, make the exact interpretation of the *Völuspá* extremely difficult. The charm and solemn beauty of the style, however, are irresistible, and we are constrained to listen and revere as if we were the auditors of some fugal music devised in honour of a primal and long-buried deity. The melodies of this earliest Icelandic verse, elaborate in their extreme and severe simplicity, are wholly rhythmic and alliterative, and return upon themselves like a solemn incantation. *Hávamál*, the Sayings of the High One, or Odin, follows next; this contains proverbs and wise saws, and a series of stories, some of them comical, told by Odin against himself. The *Vafthrúdnismál*, or sayings of Vafthrúdnir, is written in the same mystical vein as *Völuspá*; in it the giant who gives his name to the poem is visited by Odin in disguise, and is questioned by him about the cosmogony and chronology of the Norse religion. *Grimnismál*, or the Sayings of Grímnir, which is partly in prose, is a story of Odin's imprisonment and torture by king Geirrod. *För Skirnir*, or the Journey of Skirnir, *Harbarðsljóð*, or the Lay of Harbarð, *Hymiskviða*, or the Song of Hymir, and *Ægisdrekka*, or the Brewing of Ægir, are poems, frequently composed as dialogue, containing legends of the gods, some of which are so ludicrous that it has been suggested that they were intentionally burlesque. *Thrymskviða*, or the Song of Thrym, possesses far more poetic interest; it recounts in language of singular force and directness how Thor lost his hammer, stolen by Thrym the giant, how the latter refused to give it up unless the goddess Freyia was given him in marriage, and how Thor, dressed in women's raiment, personated Freyia, and, slaying Thrym, recovered his hammer. *Alvíssmál*, or the Sayings of Alvis, is actually a philological exercise under the semblance of a dialogue between Thor and Alvis the dwarf. In *Vegtamskviða*, or the Song of Vegtam, Odin questions a volva with regard to the meaning of the sinister dreams of Balder. *Rígsþula*, or more properly *Rígstula*, records how the god Heimdall, disguised as a man called Ríg, wandered by the sea-shore, where he met the original dwarf pair, Ai and Edda, to

whom he gave the power of child-bearing, and thence sprung the whole race of thralls; then he went on and met with Afi and Amma, and made them the parents of the race of churls; then he proceeded until he came to Faðir and Moðir, to whom he gave Jarl, the first of free men, whom he himself brought up, teaching him to shoot and suare, and to use the sword and runes. It is much to be lamented that of this most characteristic and picturesque poem we possess only a fragment. In *Hyndluljóð*, the Lay of Hyndla, the goddess Freyja rides to question the völva Hyndla with regard to the ancestry of her young paramour Ottar; a very fine quarrel ensues between the prophetess and her visitor. With this poem, the first or wholly mythological portion of the collection closes. What follows is heroic and pseudo-historic. The *Völundarkviða*, or Song of Völundr, is engaged with the sufferings and adventures of Völundr, the smith-king, during his stay with Nidud, king of Sweden. Völundr, identical with the Anglo-Saxon Weland and the German Welant, is sometimes confounded with Odin, the master-smith. This poem contains the beautiful figure of Svanhvít, the swan-maiden, who stays seven winters with Völundr, and then, yearning for her fatherland, flies away home through the dark forest. *Helgakviða Hjorvarðs Sonar*, the Song of Helgi, the Son of Hjorvarð, which is largely in prose, celebrates the wooing by Helgi of Svan, who, like Atalanta, ends by loving the man with whom she has fought in battle. Two Songs of Helgi the Hunding's Bane, *Helgakviða Hundingsbana*, open the long and very important series of lays relating to the two heroic families of the Volsungs and the Niblungs. Including the poems just mentioned, there are about twenty distinct pieces in the poetic *Edda* which deal more or less directly with this chain of stories. It is hardly necessary to give the titles of these poems here in detail, especially as they are, in their present form, manifestly only fragments of a great poetic saga, possibly the earliest coherent form of the story so universal among the Teutonic peoples. We happily possess a somewhat later prose version of this lost poem in the *Volsungasaga*, where the story is completely worked out. In many places the prose of the *Volsungasaga* follows the verse of the Eddaic fragments with the greatest precision, often making use of the very same expressions. At the same time there are poems in the *Edda* which the author of the saga does not seem to have seen. But if we compare the central portions of the myth, namely Sigurd's conversation with Fafnir, the death of Regin, the speech of the birds and the meeting with the Valkyrje, we are struck with the extreme fidelity of the prose romance to his poetic precursors in the *Sigurðarkviða Fáfnisbana*; in passing on to the death of Sigurd, we perceive that the version in the *Volsungasaga* must be based upon a poem now entirely lost. Of the further extension of the myth and its corruption into the romantic epic of *Der Nibelunge Nôt*, this is not the place for discussion. Suffice to say that in no modernized or Germanized form does the legend attain such an exquisite colouring of heroic poetry as in these earliest fragments of Icelandic song. A very curious poem, in some MSS. attributed directly to Sæmund, is the Lay of the Sun, *Sólarljóð*, which forms a kind of appendix to the poetic *Edda*. In this the spirit of a dead father addresses his living son, and exhorts him, with maxims that resemble those of *Hávamál*, to righteousness of life. The tone of the poem is strangely confused between Christianity and Paganism, and it has been assumed to be the composition of a writer in the act of transition between the old creed and the new. It may, however, not impossibly, be altogether spurious as a poem of great antiquity, and may merely be the production of some Icelandic monk, anxious to imitate the Eddaic form and spirit. Finally *Forspjalls-*

ljóð, or the Preamble, formerly known as the Song of Odin's Raven, is an extremely obscure fragment, of which little is understood, although infinite scholarship has been expended on it. With this the poetic *Edda* closes.

The principal MS. of this *Edda* is the Codex Regius in the Royal Library at Copenhagen, written continuously, without regard to prose or verse, on 45 leaves. This is that found by Bishop Brynjulf. Another valuable fragment exists in the Arne-Magnæan collection in the University of Copenhagen, consisting of six leaves. These are the only MSS. older than the 17th century which contain a collection of the ancient mytho-heroic lays, but fragments occur in various other works, and especially in the *Edda* of Snorri. The poetic *Edda* was translated into English verse by Amos Cottle in 1797; the poet Gray produced a version of the *Vegtamskviða*; but the first good translation of the whole was that published by Benjamin Thorpe in 1866. An excellent edition of the Icelandic text has been prepared by Th. Möbius, but the standard of the original orthography will be found in the admirable edition of Sophus Bugge, *Norren Fornkvæði*, published at Christiania in 1867. (E. W. G.)

EDELINCK, GERARD (1649-1707), one of the greatest copper-plate engravers, was born at Antwerp in 1649. The rudiments of the art, which he was to carry to a higher pitch of excellence than it had previously reached, he acquired in his native town under the engraver Cornelisz Galle. But he was not long in reaching the limits of his master's attainments; and then he went to Paris to improve himself under the teaching of De Poilly. This master likewise had soon done all he could to help him onwards, and Edelineck ultimately took the first rank among line engravers. His excellence was generally acknowledged, and having become known to Louis XIV. he was appointed, on the recommendation of Le Brun, teacher at the academy established at the Gobelins for the training of workers in tapestry. He was also entrusted with the execution of several important works. In 1677 he was admitted member of the Paris Academy of Painting and Sculpture. The work of this great engraver constitutes an epoch in the art. His prints number more than four hundred, and it is asserted that amongst them there is no work of poor or middling quality, although many of his subjects were poor and unworthy of the high art which he lavished upon them. Edelineck stands above and apart from his predecessors and contemporaries especially in this that he excelled, not in some one respect, but in all respects,—that while one engraver attained excellence in correct form, and another in rendering light and shade, and others in giving colour to their prints and the texture of surfaces, he, as supreme master of the burin, possessed and displayed all these separate qualities, and that in so complete a harmony that the eye is not attracted by any one of them in particular, but rests in the satisfying whole. Edelineck was the first to break through the custom of making prints square, and to execute them in the lozenge shape. Among his most famous works are a Holy Family, after Raphael; a Penitent Magdalene, after Charles le Brun; Alexander at the Tent of Darins, after Le Brun; a Combat of Four Knights, after Leonardo da Vinci; Christ surrounded with Angels; St Louis praying; and St Charles Borromeo before a crucifix,—the last three after Le Brun. Edelineck was especially good as an engraver of portraits, and executed prints of many of the most eminent persons of his time. Among these are those of Le Brun, Rigand, Philippe de Champagne (which the engraver thought his best), Santeuil, La Fontaine, Colbert, John Dryden, Descartes, &c. He died at Paris in 1707. His younger brother John, and his son Nicholas, were also engravers, but did not attain to his excellence.

EDEN, Hebrew (עֵדֶן, denoting pleasure or delight), was the first residence of Adam and Eve according to the Old Testament Scriptures. The passage in which its geographical position seems to be indicated (Gen. i. 8-14) has been from the earliest times the subject of a discussion as ingenious and elaborate as it has been fruitless. Its

general position is given as "eastward," i.e., to the east of the place where the narrative was written. Of the four rivers mentioned the Euphrates is undoubtedly the same which is still known by that name, and the Hiddekel has been almost universally identified with the Tigris. The object of commentators who have sought to put a literal construction on the passage has, therefore, been to identify the Pison and the Gihon, by finding two rivers which together with the Euphrates and the Tigris fulfil the condition stated in Gen. ii. 10, "And a river went out of Eden to water the garden; and from thence it was parted and became into four heads." As there is no river which forms a common source for the Euphrates, the Tigris, and two others, recourse has been had to a strained construction of one kind or other. Josephus, for example, supposes the river which is the common source to have been the ocean stream which surrounds the earth, and identifies the Pison with the Ganges and the Gihon with the Nile; and in this he is followed by many of the fathers. Calmet, Rosenmüller, and others, again, suppose the river which is the common source to have been a region of springs, and, by making the Pison and the Gihon mountain streams, place the site of Eden in the highlands of Armenia. Calvin, Huet, and Bochart place Eden in lower Babylonia, on the supposition that the Pison and the Gihon are the two channels by which the united rivers Euphrates and Tigris enter the Persian Gulf. Luther and others, such as Clericus and more recently Baumgarten, have hazarded the supposition that the flood altered the course of the streams, and thus rendered it impossible to identify the locality of Eden from the description given in Genesis. These may suffice as specimens of the almost innumerable solutions that have been offered of what is now generally admitted to be an insoluble problem. On the theory that the narrative in Genesis is veritable history to be literally interpreted, it is impossible to fix the geographical position of Eden with any approach to certainty. This impossibility fully accounts for the immense variety of the conjectures that have been put forward. It deserves mention as a curiosity of criticism that the site of Eden has been assigned by different writers to each of the four quarters of the globe, and that the particular localities specified have ranged from Scandinavia to the South Sea Islands. The allegorical interpretations, which have been offered in great variety from the time of Philo downwards, are, of course, not hampered with any geographical difficulties. Philo supposes Eden to be a symbol of the soul that delights in virtue, the river which is the source to be generic virtue or goodness, and the four rivers to be the specific virtues of prudence, temperance, courage, and justice. Origen finds in the subject an excellent opportunity for applying his favourite allegorical method, and supposes Eden to be heaven, and the rivers wisdom. Similar interpretations, with individual variations, are given by several of the fathers who are prone to allegorize. In modern times Coleridge is perhaps the most celebrated of those who have interpreted the story of Eden as an allegory. It is to be observed, however, that this mode of explaining the narrative has found even less favour with recent interpreters than that which accepts it as literal history, meeting the obvious difficulties as best it can. The undoubted tendency of later criticism has been to discard alike the theory of literal history and the theory of allegory in favour of another, according to which the story of Eden is a mythical tradition of a kind similar to that which is to be found in the early sacred literature of most nations. According to this view the true explanation is to be sought for in a careful comparison of these various traditions as preserved in sacred scriptures, early histories, inscriptions, and otherwise. See ADAM, vol. i. p. 135-6, and PENTATEUCH.

EDEN; THE HONOURABLE EMILY (1795-1851), novelist and miscellaneous writer, was the seventh daughter of the first Lord Auckland, and was born in 1795. Happily gifted by nature, her literary faculties and tastes were fostered by a liberal education. In 1835 she accompanied her brother, Lord Auckland, to India, on his appointment as governor-general, and remained with him during his term of office, which covered the period of the Afghan war. Returning to England in 1841, she made herself favourably known as a writer by the publication, three years later, of her *Portraits of the Princes and People of India*. She was also author of two novels entitled the *The Semi-detached House* and *The Semi-attached Couple*, which first appeared anonymously under the editorship of Lady Theresa Lewis. In these works she gives clever and amusing delineations of Anglo-Indian life and manners as she saw them. In 1866 was published a series of her letters to her sister written from India, and entitled *Up the Country*. Her private journal, at present unpublished, is said to be still more attractive and full of sparkling anecdote and graphic sketches. Another volume entitled *Letters from India*, edited by her niece, the Hon. Eleanor Eden, was published in 1872. For many years Miss Eden lived at Kensington, and her house was one of the most frequented centres of London intellectual and fashionable life. She afterwards removed to Richmond, and there died, August 5, 1869. Her eldest sister Eleanor attracted the warm affection of William Pitt, who, however, did not feel justified in making her an offer of marriage. This was, it is supposed, the only love-passage in Pitt's history. She afterwards married Lord Hobart, and died in 1851.

EDENTATA, an order of placental mammals characterized by the total absence of median incisor teeth. Such teeth as are found in edentate species are composed entirely of dentine and cement, without enamel, they likewise grow for an indefinite period, and are consequently without root; and so far as yet discovered there is no displacement of the first teeth by any second set except in a few of the armadillos. This order contains the sloths, armadillos, and ant-eaters.

EDESSA, the ancient capital of Macedonia, previously known as *Ægæ*, was situated 46 miles W. of Thessalonica on the banks of a beautiful stream in the very centre of the kingdom, and at the head of a defile commanding the approaches from the sea-coast to the interior of the country. It was the original residence of the Macedonian kings; and even after the seat of government was removed to the more accessible Pella, it continued to be the burial-place of the royal family. At the celebration of his daughter's marriage in the town, Philip II. was murdered by Pausanias in 336 B.C. His greater son Alexander was buried at Memphis through the contrivance of Ptolemy; but the bodies of his granddaughter Eurydice and her husband Arrhidaeus were removed by Cassander to the ancestral sepulchre. On the occupation of the town by Pyrrhus the royal tombs were plundered by the Gallic mercenaries. The modern city of Voden is built on the site of Edessa, and preserves a few unimportant remains of ancient buildings. The names *Ægæ* and Edessa were both probably given in allusion to the full-flowing streams that form one of the principal features of the situation; and Voden is certainly derived from the Slavonic *voda*, water. Full details in regard to the position of the city may be found in Tozer, *The Highlands of Turkey*, vol. i.

EDESSA, or, as it is now called, Urfa or Orfa, a city of Northern Mesopotamia, on the *Daisun*, a left-hand tributary of the Euphrates, 75 miles W. of Diarbekir and 59 E. of Biredjik, in 37° 21' N. lat. and 39° 6' E. long. It is surrounded with walls and towers, well preserved on the northern side, has narrow but comfortable and cleanly

streets, and displays in its bazaar not only the native woollen stuffs, pottery, and silver work, but also a considerable variety of European goods. In the principal square there is a large mosque dedicated to Abraham, who, according to Mahometan legend, was slain in the city; and in its immediate vicinity is a pond shaded by fine pomegranate, plane, and cypress trees, and tenanted from time immemorial by sacred fish. The only ancient remains are those of a tower ascribed by tradition to Nimrod; but in the neighbourhood there exist extensive catacombs with numerous inscriptions of an early date. The prevailing language is Turkish, though more than three-fourths of the inhabitants are Christian. The population was estimated about 1796 by Olivier as from 20,000 to 24,000; by Buckingham at 50,000; and, in 1873, by Chernik at 40,000. There are two mission establishments, an American and a French, and in connection with the former a school with about 250 pupils. The outskirts are occupied by melon-gardens, vineyards, and mulberry plantations.

Nothing is known of the origin of Edessa. It has been suggested that probably the early inhabitants were Sabæans, and that the sacred fish originally belonged to the worship of Atergatis. According to the Targum of the pseudo-Jonathan, Jerome, and Ephraem Syrus, the city is to be identified with the Ereh of Genesis x. 10, and the local tradition of the Arabs and Jews makes it the same as Ur of the Chaldees; but there is no historical basis for either identification, though the former has received the support of Michaelis, Buttman, and Von Bohlen. The first authentic mention of the city connects it with Seleucus, who appears to have greatly increased its prosperity, and was probably the bestower of the name by which it is best known in history. This, according to Stephanus, was taken from the Macedonian Edessa, from the abundance of the water in both cities, but a modern etymologist recognizes the Syrian Haditha or New Town. Another designation, Callirhoe, found in the ancient writers, undoubtedly alludes to its fountain; and it is at least possible that this may be the derivation of its modern name—Urhoi among the Syrians, Er Roha among the Arabs, and Orfa among the Turks and Christians. In the time of Antiochus VII., about 135 B.C., the city became the seat or centre of the Orhoenic kingdom, founded by Orhoi-Bar-Khevo, and governed for centuries by a series of elective monarchs. Of these the eighth in succession, Abgar Bar-Abgar, fought against Lucullus, but afterwards sided with the Romans: the fifteenth Abgar Uchomo is famous for the legendary correspondence with Christ reported by Eusebius. The city was plundered by Trajan's general Lusius Quietus, and the kingdom became tributary in 116. Restored by Hadrian it was finally abolished by Caracalla in 217, and a Roman military colony was established with the title of Colonia Marcia Edessorum. Meanwhile Christianity had been taking fast root in the city, the first church having been built as early as 202. By the time of Julian, the wealth of the Christians was sufficient to attract his revengeful cupidity; and in the course of the following century, the number of monasteries alone is said to have exceeded 300. Great theological schools were established, and the city, in fact, became one of the chief seats of Oriental learning. Most famous of all was the *Schola Persica* or Persian School; but its professors having adopted the Nestorian heresy were expelled by Martyrus the bishop, and the building was destroyed in 489, and replaced by St Mary's Church. The prosperity of the city gradually disappeared during the next five centuries, as it passed successively into the hands of the Arabs and the Seljuks. From the latter it was captured in 1097 by Baldwin de Bonillon, and for the next fifty years it continued an independent Christian countship. Baldwin's successors were his cousin Baldwin II. (1100–1118), Jocelin de Courtenay, surnamed the Great (1118–1131), and Jocelin II. (1131–1144). The negligence of this last count permitted the city to fall into the hands of Zengi of Mosul, and in 1466, the attempt of the inhabitants to recover their independence brought down the vengeance of Zengi's successor Nur-ed-din. The sultans of Egypt and Syria obtained possession in 1181, the Byzantines in 1234, the Mongolians under Tamurlane about 1393, the Turkomans and the Persians at a later date, and finally the Turks in 1637.

See Assemani *Biblioth. Orient.* vol. I. where the "Chron. Edessenum" is reprinted. Th. L. Mayer, *Historia Orhoenis et Edessena ex nummis illustrata*, St Petersburg, 1734.

EDFU, in Coptish Atbo, from the old Egyptian Tobn, a village of Upper Egypt, in the province of Said, situated about a third of a mile from the left bank of the Nile, 55 miles below the cataracts of Syene, in 24° 58' 43" N. lat. It is inhabited by about 2000 Arabs and Copts, engaged

for the most part in the manufacture of earthenware, which finds ready sale all through Egypt, and is remarkable for the similarity it retains to the ancient pottery represented on the monuments. To the Egyptologist the spot is of extreme interest, as furnishing the most perfect specimen of an ancient Egyptian temple, full details in regard to which may be found in the article *ARCHITECTURE*, vol. ii. p. 389. By the Greeks and Romans the city to which this splendid building belonged was known as Apollinopolis Magna, the god to whom the temple was dedicated being identified with the Greek Apollo. Under the later empire it was the see of a bishop and the head-quarters of the Legio II. Trajana.

See Belzoni, *Narrative*, 3d ed., 1822, Wilkinson, *Egypt and Thebes*, 1843; Lepsius, *Ueber eine hieroglyphische Inschrift am Tempel von Edfu*, Berlin, 1855; Mariette, *Fouilles exécutées en Egypte, &c., d'après les ordres du vice-roi*, 1867.

EDGEWORTH, MARIA (1767–1849), the creator of the novel of national manners and moral purpose, was the daughter, by her first wife, of Richard Lovell Edgeworth noticed below. She was born at Hare Hatch, Berkshire, in 1767, and did not see Ireland till she was twelve years old. She was educated by her father, who devoted himself with great enthusiasm to the intellectual advancement of his children. In most of her literary undertakings Miss Edgeworth had the advantage of her father's criticism, who also wrote introductions to her novels. "It is my business," he used to say, "to cut and correct: yours to write on." Many tales and essays were written by Maria for private pleasure before publication was thought of. *Practical Education* (1798) was a joint work by father and daughter. In 1800 appeared *Castle Rackrent*, which at once made for her a reputation as a national novelist. This was followed soon after by *Belinda*, and by the *Essay on Irish Bulls*, published in partnership with her father, and intended to familiarize the English public with Irish humour and pathos. The work is so thoroughly the joint-product of two minds, that Miss Edgeworth, in writing her father's life, cannot tell distinctly which parts are his, but says that passages in which classical allusions and quotations occur must be her father's, as she was "entirely ignorant of the learned languages" (*Memoirs*, second edition, ii. 315). In 1804 appeared *Popular Tales*; in 1806 *Leonora*, in 1809 the first instalment of *Fashionable Tales*, which were finished in 1812; in 1814 *Patronage*; and in 1817 *Harrington, Ormond, and Comic Dramas*, which failed on the stage. The death of her father, in that year, recalled her from novel writing to fulfil the sacred duty of completing his *Memoirs*, which were given to the world in 1820, and of which a second edition was called for in 1821. In 1822 appeared *Rosamond, a Sequel to Early Lessons*, a work published earlier with contributions from Mr Edgeworth's pen. In August 1823 Miss Edgeworth visited Sir Walter Scott at Abbotsford, where she remained a fortnight; and Scott repaid this visit at Edgeworthstown exactly two years afterwards. In 1825 Miss Edgeworth further continued her tales for the young by the publication of *Harry and Lucy*. In 1834 appeared *Helen, a Tale*, her last and one of her best novels; and she afterwards wrote *Orlandino*, a book for children. Her *Letters for Literary Ladies* were suggested by a correspondence between Thomas Day and her father as to the propriety of "female authorship," in which the former stoutly maintained the negative.

Miss Edgeworth died on the 21st of May 1849, after having lived to see her works take rank as English classics. Her influence was deep and lasting. Sir Walter Scott confesses that he was anxious to do for Scotland what Miss Edgeworth had done for Ireland; and it is said that O'Connell regretted deeply that one so powerful did not serve Ireland as an agitator. Her society was courted by

the most distinguished of her contemporaries; and countless tourists, who visited her, returned home charmed by her lively conversation and by the domestic virtues which brightened the home of which she was the centre. With Scott she was on terms of the closest intimacy; Byron admired her works, in spite of his sarcastic reference to "Miss Edgeworth's novels stepping from their covers;" and Lord Macaulay was one of her most enthusiastic worshippers. "Among all the incidents," says Mr Trevelyan, "connected with the publication of his *History*, nothing pleased Macaulay so much as the gratification that he contrived to give to Maria Edgeworth, as a small return for the enjoyment which, during more than forty years, he had derived from her charming writings." Macaulay mentions Miss Edgeworth's name in a note, in which he describes her delineation of King Corny, in *Ormond*, as "that admirable portrait." Miss Edgeworth, in a letter to Dr Holland, speaks of the "self-satisfaction, vanity, pride, surprise, I had in finding my own name in a note."

Castle Rackrent, the first and one of the most characteristic of her novels, is lit up throughout with sunny Irish humour, Sir Condy complaining that he "was very ill used by the Government about a place that was promised him and never given, after his supporting them against his conscience very honourably" (1857 edition, p. 39). *Leonora* has a painful plot. It treats of the seduction of an attached husband by a professed friend of his wife. Leonora's forbearance, however, and her deep-seated love for her husband prove, in the end, too much for the hollow professions and vaunted "sensibility" of Olivia. The *Tales of Fashionable Life* include *Ennui*, *The Dun*, *Manœuvring*, *Almeria*, *Vivian*, *The Absentee*, *Madame de Fleury*, and *Emilie de Coulanges*. *Ennui* is a powerful story, and relates how the earl of Glenthorn was cured of the disease which gives its name to the book. There are several fine character studies, including the Earl; McLeod, the cool, but faithful, Scotch agent; witty Lady Geraldine; Christy, the blacksmith; and Ellinor, the Irish foster nurse, who said, on one occasion, that "if it pleased God, she would like to die on a Christmas day, of all days, because the gates of Heaven, they say, will be open all that day, and who knows but a body might slip in unknown?" (1857 edition, p. 231). *The Dun* portrays, with a realism almost too painful, the dreadful privations undergone by the poor who are unable to get in the money justly their due. *Manœuvring* depicts the efforts of Mrs Beaumont, a clever, scheming, deceitful woman, to marry her son and daughter contrary to their inclinations. For a while all seems to go well with Mrs Beaumont, until she is herself entangled in her net of white lies, and finally thoroughly outwitted. Her character, and that of Mr Palmer, a wealthy merchant from Jamaica, are worthy of the author's high reputation. *Almeria* traces the rise of the worldly spirit in the breast of a young girl, and the debasing consequences of a passionate pursuit of fashion for its own sake, unredeemed by any ennobling feature. *Vivian* is an admirably told story, and illustrates the terrible evils which sometimes arise from indecision of character. Vivian, the undecided, brilliant, young noble; Russell, the faithful tutor; Wharton, the unscrupulous politician and voluptuary; self-willed Lord Glistonbury; prim Lady Glistonbury; and vivacious Lady Julia seem to start from the canvas. *The Absentee*, considered by many as Miss Edgeworth's masterpiece, is written to expose the misery entailed on the tenantry by the Irish gentry, who deserted their native country for London, and abandoned their affairs to be managed by unscrupulous agents. The characters are among the most life-like in the annals of fiction. Lady Clonbrony makes herself exquisitely ridiculous in her vain

endeavours to act the fine English lady; Lord Colambre, the hero of the novel, travels, under an assumed name, among his father's tenants in Ireland, finds out how rudely they have been oppressed, and champions their cause so skilfully as to win over even Lady Clonbrony; Lady Dashford and her daughter are wonderfully real representations of heartless women of fashion; the sufferings of the Irish peasantry are drawn with a loving and masterly pencil; and the general sadness of the work is relieved by such humorous sketches as Colonel Heathcock, Sir Terence O'Far, and Larry Brady, whose inimitable letter closes the book. Macaulay considered the scene in which Lord Colambre discovers himself to his father's tenantry the best passage of the kind since the beginning of the 22d book of the *Odyssey*. This is very high praise, especially when we remember that Macaulay seems to have read almost every novel—so much was he fascinated by narrative composition. *Madame de Fleury* is the story of a French lady who set up a school in Paris for neglected girls. The school came to grief at the great Revolution; and its benevolent founder had to fly to England, where she was supported mainly by donations from the girls, who were instigated by Victoire, the heroine of the book. Ultimately her return to France was secured by Basile, Victoire's lover, who had obtained influence with his general through his valuable engineering knowledge. *Emilie de Coulanges* describes the mortifications two French refugees had to undergo in living with Mrs Somers, an excessively ill-tempered English lady, who was generous enough with her money, but neglectful of kindness of a more delicate order. Mrs Somers's incessant outbursts of temper and reconciliations with Emilie, to be followed inevitably by fresh quarrels, are somewhat wearisome reading. *The Modern Gracinda*, a story treating of the attempts of a wife to bring her husband to abject submission, manifests fine satiric power, and great liveliness—the dialogue being particularly animated. *Patronage*, which is in the same vein as the *Tales of Fashionable Life*, rather disappointed the critics, who concluded that Mr Edgeworth had written considerable parts of it. This, however, is expressly denied by Miss Edgeworth (*Memoirs*, ii. 323). *Ormond* is an Irish tale, and ranks among the best of Miss Edgeworth's works. It shows how a youth, whose education had been neglected, and whose temper was naturally impetuous, managed to reach true nobility of character. King Corny, Ormond, Sir Ulick O'Shane, Moriarty Carroll, Dora, and Mademoiselle O'Faley are masterly creations. There is a true Irish ring about the book, although it is composed in the purest English. *Helen* is a novel of thrilling interest, and displays greater passion and a finer insight into the more subtle moods of the human mind than any of Miss Edgeworth's previous works. The moral is that falsehood and deceit almost invariably bring misery in their train. Although on a more elaborate scale than her other books, *Helen* surpasses them all in grace, charm, and lightness of touch. Such powerfully conceived characters as Lady Davenant, Helen, Cecilia, Beanelere, Churchill, and the Clarendons, leave an indelible impression on the memory.

Miss Edgeworth's novels are distinguished by good sense, humour, and an easy flowing style. As the construction of a plot is not her strong point, she is generally more successful in tales than in lengthy novels. The vivacity of her dialogues is extraordinary; and in them her characters reveal themselves in the most natural way possible. Her books are character-studies, rather than intensely interesting narratives. Sobriety of judgment is seen throughout; and passion, romance, and poetry rarely, if ever, shed their lustre on her pages. Three of her aims were to paint national manners, to enforce morality, and to teach fashionable society by satirizing the lives of the idle and worldly. She expressly calls some of her stories "Moral Tales"; but they all fall under this category. The two poles of thought in regard to the moral tendency of Miss Edgeworth's works are well represented by Robert Hall, the eminent Baptist preacher, and Monsieur Taine.

Miss Edgeworth "does not," says Hall, "attack religion or inveigh against it, but makes it appear unnecessary by exhibiting perfect virtue without it. No book ever produced so bad an effect on my own mind as hers. I did not expect any irreligion there. I was off my guard, their moral character beguiled me: I read volume after volume with eagerness, and the evil effects of them I experienced for weeks" (Hall's *Works*, vol. i. Bohn's edition, 1846, appendix, note A). Monsieur Taine, again, says that "this regular presence of a moral intention spoils the novel as well as the novelist. It must be confessed a volume of Thackeray has the cruel misfortune of recalling the novels of Miss Edgeworth" (*English Literature, Criticism on Thackeray*). To Robert Hall's criticism it is to be objected that a novel is scarcely the place to explain and inculcate the systematic theology of the evangelical school; while we must concede to Taine and the French critics that to burden a novel with a moral, or other special purpose, is artistically a blemish, especially when it is professedly made an aim as in Miss Edgeworth's case. She remarks very beautifully of Sir Walter Scott, that "his morality is not in purple patches, ostentatiously obtrusive, but woven in through the very texture of the stuff" (*Helen*, 1838 edition, 123)—a statement which scarcely holds true of herself. Still, strong national tendencies must be allowed to assert themselves in fiction, and there can be no doubt that the didactic or moralizing tendency is deeply seated in the English-speaking peoples.

No writer teaches a more admirable practical philosophy than Miss Edgeworth; and she reaches her object by making her characters natural, and capable, as well as worthy, of imitation. She plainly belongs to the realistic school of fiction; and it is interesting to remember that her Tales are expressly founded on a carefully thought out philosophy of education. She thus gives no countenance to the popular fallacy that teaching is a mere trick or knack, rather than a science resting on well-ascertained mental phenomena. Few novelists display less extravagance than Miss Edgeworth. We feel that her minor characters especially are genuine flesh and blood. Sometimes the hero or heroine of the story is liable to the charge of being the incarnation of a single quality, rather than a man or woman. However, in the case of one who writes with a didactic purpose, this is almost inevitable. Miss Edgeworth has drawn attention to the less brilliant faculties of humanity, and always prefers to be useful, where others would have endeavoured to be striking. In her pages the heroic virtues give place to prudence, industry, kindness, and sweetness of temper. There are few instances of overwhelming emotions or tumultuous passions in her works; and it is remarkable how little the love of nature appears. She never uses material which does not yield some direct moral lesson. All this is the natural consequence of Miss Edgeworth's method and utilitarian aim. But, working under such self-imposed conditions, she has done wonders. Her representations of the humour, pathos, and generous character of the Irish peasantry are an imperishable monument of her genius. Nor is it fair to depreciate the English novels in comparison, *Helen* being quite equal to any of her distinctively national tales. The freshness of her stories, her insight into character, lively dialogues, originality of invention, and delightfully clear style render it quite possible to read her works in succession without any sense of weariness. As a painter of national life and manners, and an illustrator of the homelier graces of human character, Miss Edgeworth is surpassed by Sir Walter Scott alone; while as a direct moral teacher she has no peer among novelists. Among the many sweet memories her unsullied pages have bequeathed to the world, not the least precious is her own noble character, which ever responded to all that is best and most enduring in human nature.

In 1812 a collected edition of Miss Edgeworth's novels was published in London in 18 volumes.—I. *Castle Rackrent; Essay on Irish Bulls; Essay on Self-Justification*. II. *Forester; the Prussian Vase; the Good Aunt*. III. *Angelina; the Good French Governess; Mademoiselle Panache; the Knapsack*. IV. *Lame Jeremia; the Will; the Limerick Gloves; Out of Debt, Out of Danger; the Lottery; Rosanna*. V. *Murad the Unlucky; the Manufacturers; the Contrast; the Grateful Negro; To-morrow*. VI. *Ennui; the Dun*. VII. *Minstreling; Almeria*. VIII. *Velan*. IX. *The Absentee*. X. *Absentee (concluded); Madame de Fleury; Emile de Couranges; the Modern Graciana*. XI. and XII. *Belinda*. XIII. *Leonora; Letters*. XIV. and XV. *Patronage*. XVI. *Comic Dramas*. XVII. *Marriage; Thoughts on Boredom*. XVIII. *Ormond*. To this list are to be added *Essays on Practical Education*, written in conjunction with Mr Edgeworth (1789), *Helen* (1834), and numerous stories and books for children. In 1848 a new collected edition of Miss Edgeworth's works appeared in London in nine volumes, and, after her death, an edition was published in ten volumes, with steel engravings. (T. G.)

EDGEWORTH, RICHARD LOVELL (1744–1817), father of the subject of the foregoing notice, and her associate in many literary undertakings, was born at Bath in 1744. The greater part of his life, however, was spent at Edgeworthstown, or Edgeworthstown, in the county of Longford, Ireland, where the Edgeworth family had been settled for upwards of 150 years. He was of gentle blood—his father being the son of Colonel Francis Edgeworth, and his mother, Jane Lovell, being the daughter of

Samuel Lovell, a Welsh judge. Richard's mother taught him to read at a very early age; his young imagination was nurtured on the beautiful stories in the book of Genesis and on Shakespeare's characters of Coriolanus and Julius Cæsar; and, when he was only seven years old, a Mr Deane explained to him the uses and structure of several pieces of machinery, a circumstance to which he over afterwards traced his strong love for mechanical science. The Rev. Patrick Hughes initiated him in Lilly's *Latin Grammar*—an office he also performed for Goldsmith, who was born on the property of the Edgeworths—and his public education began, in August 1752, in a school at Warwick. He subsequently attended Drogheda school, then reputed the best in Ireland; and, after spending two years at a school in Longford, entered Trinity College, Dublin, in April 1761, from which he was transferred to Corpus Christi College, Oxford, in October of the same year. While still at college, he made a runaway match, marrying at Gretna Green one of the daughters of Mr Paul Elers, an old friend of his father, by whom he had a son, who was born before Edgeworth reached his twentieth birth-day, and his daughter Maria. Shortly after the birth of his son, he and his wife went to Edgeworthstown, where he met a severe trial in the death of his mother. Her dying advice to him, to "learn how to say no," was the germ of *Vivian*, one of Miss Edgeworth's best novels. For some time after this Edgeworth devoted himself to scientific reading and experiments; and he claims to be the reviver of telegraphic communication in modern times (*Memoirs*, second edition, i. 144). His home was now at Hare Hatch, in Berkshire, where he endeavoured to educate his son according to the method explained in Rousseau's *Emile*. In later life, however, he saw reason to doubt many of Rousseau's views (*Memoirs*, ii. 374). At the same time he went on keeping terms at the Temple, and formed the greatest friendship of his life with Thomas Day—an able man, of noble character, excessively eccentric, and known to all boys as the author of *Sandford and Merton*, which was written at Edgeworth's suggestion. In 1769, on the death of his father, he gave up the idea of being a barrister; but, instead of immediately settling on his Irish estate, he spent a considerable time in England and France, mainly in Day's company. In Lyons, where he resided for about two years, he took an active part in the management of public works intended to turn the course of the Rhone. He was summoned to England by the death of his wife, with whom his autobiography tells us plainly he was not happy. Edgeworth hurried to Lichfield, to Dr Erasmus Darwin's, one of his greatest friends, and at once declared his passion for Miss Honora Sneyd, which had been the cause of his flight to France two years before. They were married (1773) in the cathedral, and after residing at Edgeworthstown for three years, settled at Northchurch, in Hertfordshire. When six years of great domestic happiness had elapsed, Mrs Honora Edgeworth died, after recommending her husband to marry her sister Elizabeth—which he did, on Christmas Day 1780. In 1782 Edgeworth returned to Ireland, determined to improve his estate, educate his seven children, and ameliorate the condition of the tenants. Up to this point Edgeworth has told his own story. The rest of his life is written by his daughter, and opens with an account of the improvements he effected, and a lengthy panegyric on Mr Edgeworth as a model landlord (*Memoirs*, ii. 12–36). In 1785 he was associated with others in founding the Royal Irish Academy; and, during the two succeeding years, mechanics and agriculture occupied most of his time. In October 1789 his friend Day was killed by a fall from his horse, and this trial was soon followed by the loss of a daughter, who had just reached her fifteenth

year. The first thing that broke the monotony of his grief was the arrival of Dr Darwin's poem, the *Botanic Garden*, about which the author says, "It was your early approbation that contributed to encourage me to go on with the poem" (*Memoirs*, ii. 113). In 1792 the health of one of Edgeworth's sons took him to Clifton, where he remained with his family for about two years, returning in 1794 to Edgeworthstown. Ireland was, at that time, harassed by internal disturbances, and threats of a French invasion, and Edgeworth offered to establish telegraphic communication of his own invention throughout the country. This offer was declined. A full account of the matter is given in Edgeworth's *Letter to Lord Charlemont on the Telegraph*; and his apparatus is explained in an "Essay on the Art of Conveying Swift and Secret Intelligence," published in the sixth volume of the *Transactions of the Royal Irish Academy*. In the autumn of 1797 Mrs Edgeworth fell a victim to decline. *Practical Education*, a work which embodied the experience of the authors in dealing with children, was published in 1798. "So commenced," says Miss Edgeworth, "that literary partnership which, for so many years, was the pride and joy of my life" (*Memoirs*, ii. 170). In the same year Edgeworth married Miss Beaufort, and was elected M.P. for the borough of St John's Town, Longford. The same year, too, saw a hostile landing of the French and a formidable rebellion; and for a short time the Edgeworths took refuge in Longford. The spring of 1802 brought the depressing announcement of Dr Darwin's death; and the winter of that year was spent by the Edgeworths in Paris, where, among many friends, they particularly valued M. Dnmont. On his return home he was gratified by Government accepting of his telegraphic apparatus, which worked admirably. In 1802 appeared the *Essay on Irish Bulls* by Mr and Miss Edgeworth; and in 1806 Edgeworth was elected a member of the Board of Commissioners to inquire into Irish education. From 1807 till 1809 much of his time was spent on mechanical experiments and in writing the story of his life. In 1808 appeared *Professional Education*, and in 1813 his *Essay on the Construction of Roads and Carriages*. He died on the 13th of June 1817, and was buried in the family vault in Edgeworthstown churchyard.

Many of Edgeworth's works were suggested by his zeal for the education of his own children. Such were *Poetry Explained for Young People*, *Readings on Poetry*, *A Rational Primer*, and the parts of *Early Lessons* contributed by him. His speeches in the Irish Parliament have also been published; and numerous essays, mostly on scientific subjects, have appeared in the *Philosophical Transactions*, the *Transactions of the Royal Irish Academy*, the *Monthly Magazine*, and *Nicholson's Journal*. The story of his early life, told by himself, is fully as entertaining as the continuation by Maria, as it contains less dissertation and more incident. (T. GL.)

EDINBURGH, COUNTY OF, or MID-LOTHIAN, one of the lowland counties of Scotland, is situated between 55° 39' 30" and 55° 59' 20" N. lat., and between 2° 52' and 3° 45' 10" W. long. It is bounded on the N. by the Firth of Forth, on the N.W. by Linlithgowshire or West-Lothian, on the S.W. by Lanarkshire, on the S. by Peebles and Selkirk, and on the E. by Roxburgh, Berwick, and Haddington or East-Lothian. The area comprises 362 square miles, or 231,724 acres.

The surface of the county presents a great variety of scenery. The Pentland Hills advance boldly from the south-west to within five miles of the sea, rising to a relative height of from 1000 to 1300 feet. The loftiest summits are Scald Law (1898 feet), Carnethie (1890), West and East Cairn Hill (1844 and 1839), and West Kip (1806). They generally present a rounded appearance, and are covered with heath or grass. The south-eastern corner of the county is occupied by the Moorfoot Hills, which form a continuation of the Lammermuirs, and attain in Blackhope

Scar a height of 2136 feet. Of more or less isolated eminences throughout the county it is enough to mention the Braid Hills and Blackford Hill to the S. of the city, Arthur's Seat towards the E., Corstorphine Hill about two miles to the W., and Dalmahoy Crags about seven miles to the S.W.

With the exception of the Gala, which rises on the south-east side of the Moorfoot Hills and flows south to join the Tweed, and the partial exception of the Tyne, which after a course of about seven miles passes into Haddingtonshire, all the streams, we cannot say the rivers, find their way to the Firth of Forth. The Esk (the largest) drains the district between the Pentlands and the Moorfoot Hills, and falls into the sea at Musselburgh. The southern branch has its sources near Blackhope Scar, receives the Redside and Middleton Burns, and flows past Newbattle Abbey; the northern rises in the Pentlands, and proceeds through much picturesque scenery, past Penicuik, Roslin, Lasswade, and Eskbank; and the union of the two streams takes place a short distance below Dalkeith, within the grounds of Dalkeith Palace. The Braid Burn from Capelaw Hill passes between the Braid Hills and Blackford Hill, and reaches the sea at Portobello. The Water of Leith, with its head streams on the western slope of the Pentlands, flows past Balerno, Currie, Juniper Green, Colinton, Edinburgh, and Leith. The Almond, which has its origin in Lanarkshire, and its right-hand tributary the Breich Water, form the boundary between Mid-Lothian and Linlithgowshire. Most of these streams, and especially the Esk and the Water of Leith, afford a large amount of water-power, well-preserved by means of artificial dams and embankments. The deep ravines which in some places they have formed in the Carboniferous strata through which they flow conceal spots of romantic beauty, in striking contrast to the immediately contiguous scenery. The only lake is that at Duddingston, near Edinburgh; but there are several extensive reservoirs connected with the water supply of the city, viz.—Threipmuir, Loganlee, Harelaw, Clubbiedean, and Torduff in the Pentlands, and Gladsmuir and Rosebery on the South Esk. The Cobbiashaw reservoir, situated at the head of the Bog Burn, a tributary of the Almond, is used for the supply of the Union Canal.

The geology of Mid-Lothian is of interest, not only from its intrinsic characteristics, but also as the subject of investigation of many of the most famous among Scottish geologists—Hutton, Hall, Jameson, Cunningham, Hugh Miller, Fleming, and others. The Lammermuir and Moorfoot Hills are a continuation of the Silurian tableland of the south of Scotland, and consist mainly of strata of greywacke, grit, and shale, greatly contorted, broken, and altered in position. Sandstones, grits, shales, and mud-stones of the Upper Silurian occur in three very limited areas in the Pentland Hills, in the midst of Lower Old Red Sandstone formations. They are abundantly fossiliferous, especially on the North Esk,—*Chondrites verisimilis*, *Amphispongia oblonga*, *Protaster Sedgwicki*, *Pterygotus acuminatus*, various *Strophomenas*, and *Euomphalus fumatus* being among the characteristic forms. The Lower Old Red Sandstone formations just mentioned are a massive series of grits, conglomerates, and volcanic rocks, resting unconformably on the Upper Silurian series; the Upper Old Red Sandstone is found only in a few small patches in the hollows of the Lower Silurian. All the four series into which it is usual to divide the Carboniferous system are well represented. The Calcareous Sandstone series breaks up into two groups—the former consisting of reddish sandstones, and forming the south-western eminences of the Pentland Hills and nearly the whole site of the city of Edinburgh; while the latter comprises white and grey sandstones, shales, limestone, and coal, and furnishes a good portion of the

mineral wealth of the county. The Carboniferous Limestone series consists of strata of white and grey sandstones, shales, fire-clays, coal, and oncrinal limestone,—one section being known as the "Edge coals" from the almost vertical displacement of the beds. The strata of the Millstone Grit are not very extensive—only appearing in a narrow band round the central part of the Dalkeith coal-field, and in a limited area to the south of Penicik. The history of the igneous rocks which are sporadically distributed through the county is still matter of dispute,—the main question debated being whether the volcanic activity which has left its traces took place exclusively in the Carboniferous period, or broke out again later. The spot round which the discussion has principally been maintained is Arthur's Seat, which is the centre of the intrusive movement, although considerable masses of intrusive basaltic rocks make their appearance in many other localities. Diorite is the principal rock of Corstorphine Hill, and occurs also to the west of Ratho. Marks of glacial action may be observed at Corstorphine, Granton, Arthur's Seat, and on the Pentland Hills; and large beds of boulder-clay are present in the lower districts. Boulders of distant transport are rather rare, but a few apparently from the Ochils or even the Grampians may be discovered.¹

The cultivated condition of the county is incompatible with a varied or remarkable fauna; but the botanist finds a rich harvest of smaller plants. Arthur's Seat and the Queen's Park, in spite of their proximity to the city, yield a considerable number of very rare specimens. Details may be sought in Professor Balfour's *Flora of Edinburgh*.

The climate naturally differs in different districts, according to elevation and distance from the sea. From observations made at Inveresk, 90 feet above the sea-level, which may be taken as fairly representative, the annual mean of the barometer has only once fallen as low as 29.68 in the twenty-one years from 1855 to 1875, and usually exceeds 29.85. The maximum cold ranged from zero in 1860 to 22° in 1872; the maximum heat from 73° in 1862 to 88° in 1868 and 1873; and the mean annual temperature from 44° in 1855 to 48.2° in 1868. The average temperature of the six summer months beginning with April reached 55.8° in 1868, and sank to 51.6° in 1872. The annual rainfall varied from 16.50 inches in 1870 to 32.89 in 1862; and the number of fair days from 162 in 1872 to 247 in 1869. The greatest rainfall takes place in August at Edinburgh, Meadowfield, and Bonnington; but in January in the Pentlands. According to observations made at Inveresk over a period of 15 years, the wind blow from the N. 31 days, N.E. 40, E. 22, S.E. 24, S. 51, S.W. 119, W. 56, and N.W. 24. The N.E. and E. winds prevail in March and April, and especially in the neighbourhood of the city are remarkable for their cold and blighting character. Snow seldom lies long except in the uplands; but night frosts occur even as late as the beginning of June, severe enough to destroy the young shoots of the seedling trees in the nursery grounds.² On the shores of the Firth, along the Almond and Esk, and in some of the richer flats the grain

crops ripen early; two miles nearer the hills and 200 feet higher the harvest is ten days later; and at an elevation of 600 feet another week at least intervenes.

The total area in cereals in 1876 was 38,189 acres. The quantity of wheat grown is gradually diminishing, occupying in 1876 only 4456 acres in contrast to 10,123 in 1856. The average produce in the more fertile districts is 31 bushels per acre, in the poorer districts from 24 to 25 bushels. The roots of the plant are in some seasons attacked severely by the larva of the crane-fly (*Tipula oleracea*), and the ears sometimes suffer from the wheat-midge. Of other cereals there were in barley 10,123 acres in 1856, and 11,982 in 1876 (the return varying from 42 to 48 bushels), and in oats 23,121 in 1856, and 21,311 in 1876. Reans declined from 802 acres in 1866 to 467 in 1876. The area of sown grasses has greatly extended, being 26,907 acres in 1866, and in 1876, 31,869. The grass-seed is usually put in with the barley crops. Near the city sewage-farming has been carried on to a remarkable extent. The Craigentney meadows between the city and the sea, comprising 200 acres, have been under sewage cultivation for upwards of 30 years. The produce, now consisting principally of natural grasses, is sold at from £16 to £28 per acre, and the whole realizes from £3000 to £4000 per annum. About 80 acres are under similar treatment at Lochend, 70 acres at Dalry, and 16 at the Grange. The total produce of the whole area under irrigation is estimated at £6000. The acreage of turnips in 1856 was 14,517, in 1876, 13,312. About 16 or 18 tons of swedes, or 22 or 23 tons of common turnips, is considered a good crop for first-rate land. Potatoes hold much the same position as in former years, though the demand for them is not so great. A considerable quantity is despatched to England for seed purposes, while the seed required in the county is obtained from Perth, Lanark, or the neighbouring counties. The number of cattle was in 1862, 13,013, in 1876, 18,661. In the neighbourhood of Edinburgh especially, dairying forms a very important industry, the number of milk cows in the county is probably 11,000 or 12,000, of which 1800 or 2000 are kept in the town or suburbs, and supply about half of the milk necessary for the local consumption. Sheep are returned as—113,479 in 1866, and 168,565 in 1876. Very few horses are bred in the county, but several of the studs are of excellent character. The Clydesdale blood predominates. Pigs form a very small item in the list of stock, and the poultry yard is of distinct importance only in the farms in the neighbourhood of the city. The crop rotations vary considerably in different districts. Oats, potatoes, wheat, turnips, barley, and hay or pasture is a common order; while a five-course shift of oats, potatoes and turnips, barley or wheat, hay, pasture, or a six-course shift (oats, beans, wheat, turnips, barley, grass), is used elsewhere. The average size of farms is 131 acres. According to the returns, out of a total of 1012 holdings 477 did not exceed 50 acres, 116 lay between 50 and 100, 294 were over 100 and under 300, 75 were from 300 to 500, and only 50 were more than 500. Leases of nineteen years are common; the change of proprietor is as frequent as that of the tenants, and in some cases the same tenant has continued to hold a farm under six or eight successive landlords. The average value of the arable land is calculated at from 40 to 65 shillings the acre; that of the upland pastures at from 10 to 15 shillings. The whole of the county has been drained more or less thoroughly, and some portions twice over. Tiles and small stones began to be laid about 1830, with a distance between the drains of about 36 feet; and since 1845 deeper drains, with pipes and collars, have been put into the intermediate furrows. Great improvements have been effected not only in the farm-houses and standings since 1835, but also in the cottages for the labourers, which now for the most part contain a sitting-room and two or even three bedrooms. Steam thrashing-machines and grinding mills are not uncommon. The reaping-machine has been generally adopted within the last 20 years, except for very difficult ground, or where the crop has been laid by wind or rain. The assistance of the steam plough has hitherto been very partially obtained.

The nursery grounds of Mid-Lothian are more extensive than those of any other county of Scotland; and in the variety and quantity of their productions they are equal to any in Britain. To orchards proper there are devoted about 72 acres; and no less than 775 acres, mainly in the vicinity of the city, are devoted to market gardening. Further details on the whole subject of Mid-Lothian agriculture may be found in Thomas Farrall's paper in *Trans. of Highland and Agricultural Society*, 1877.

It appears from the Owners and Heritages Return, 1872-73, that the county, exclusive of Edinburgh and Leith, was divided among 3237 owners, holding land the yearly value of which amounted to £581,603. Of the owners 781 per cent possessed less than 1 acre, and the average value per acre over all was £2, 11s. 3d. There were 9 proprietors holding upwards of 5000 acres, viz., Earl of Rosebery (Dalmeny), 15,568; Sir G. D. Clerk (Penicuik), 12,696; Robert Dundas (Arnsfoot), 10,184; the Stair family (Oxenford), 9609; Heirs of Alex. Mitchell (Stow), 5035; Earl

¹ See Fleming's *Lithology of Edinburgh*; Hugh Miller, *Edinburgh and its Neighbourhood*; MacLaren, *Sketch of the Geology of Fife and the Lothians*; Arch. Geikie, *The Geology of Edinburgh and its Neighbourhood*, 1871; Sheet No. 32 of the one-inch Geol. Survey Map, with the accompanying memoir; and several other papers in the *Transactions of the Edinburgh Geological Society*.

² The mildness of the winter is well illustrated by the fact that Mr M'Nab of the Royal Botanic Gardens reported 138 species of flowers in bloom on New Year's Day 1874, of which 36 were winter or spring flowers, and 103 summer or autumn flowers. The *Galanthus nivalis*, or common snowdrop, blossoms, according to an average of 20 years, on the 25th of January, the *Hepatica triloba* on the 31st, and the *Rhododendron nobleanum* on the 25th of February.

of Morton (Dalmahoy), 8944; G. K. E. Fairholm, 6200; Charles Cowan (Loganhouse), 5677; John Borthwick (Crookston), 5239. The duke of Buccleuch's property, though comprising only 3541 acres, is the highest on the valuation roll (£28,296), with the exception of that of the railway companies.

Minerals—Though not a mining district *par excellence*, Mid-Lothian possesses a considerable amount of mineral wealth. There are 19 collieries, which in 1876 employed 2179 persons and raised 715,803 tons of coal. With the exception of 90,000 tons raised in the parish of West-Calder, this was all obtained in the valley of the Esk. In its general character the coal does not differ from ordinary Scotch coal, but a large quantity of the best cannel coal, used for making gas, is procured at Niddrie Colliery, and from the marquis of Lothian's mines at Newbattle and Dalkeith. The depth of the pits varies from 50 to 180 fathoms. On the east side of the Esk the strata lie at an angle of from 10° to 14°; those on the west side, at Niddrie and Gilmerton, at from 60° to 90°. Of blackband ironstone about 61,262 tons were raised in 1876, principally in the parishes of Lasswade and Penicuik; and 25,172 tons of fire-clay were obtained in the county. In the vicinity of West-Calder there is a large amount of shale, containing from 20 to 30 gallons of oil per ton. The extraction of the oil by distillation in retorts was introduced about 1862. About 258,278 tons were raised in 1876. Limestone is of frequent occurrence—at Esperton in the south; at Cousland, Crichton, Burdielehouse, and Gilmerton, near Edinburgh; at the Camps, in Kirknewton parish; and at Mureston and Levensat, still further west. Freestone is quarried at Craigleith, Redhall, Hailes, and Craigmillar. From Craigleith was obtained the greater part of the stone for the new town of Edinburgh; Hailes furnishes an excellent material for pavements and stairs; and Craigmillar has been appropriated by the builders of the new docks at Leith. Barnton Mount supplies large blocks of whinstone, which have been exported to England for docks, and even to Russia, for fortifications; the causeway stones for the streets of Edinburgh are mainly procured from the quarries at Ratho; and a large number of smaller quarries for the supply of road-metal are scattered throughout the county.

Manufactures¹—Owing its origin no doubt to the development of literature and publishing in the metropolis, the chief manufacturing industry in Mid-Lothian is paper-making. There are 22 paper mills in the county, most of them large and extensive works; and their aggregate annual production is 18,500 tons of writing and printing, and 5000 tons of coloured and wrapping paper. The most important mills, some of them dating from the beginning of the last century, are situated on the North Esk between Penicuik and Musselburgh, all producing writing and printing papers, while on the South Esk at Newbattle coloured papers are manufactured. On the Water of Leith there are eight separate mills, as well as one near Mid-Calder, and another at Portobello. An ancient vat-mill, called Peggy's Mill, still exists at Cramond, producing hand-made hosiery papers, &c. There is a carpet factory on the Esk at Roslin, and the well-known establishment at Lasswade, where velvet-pile and tapestry carpet was produced under Whytock's patent, is now removed to Bonnington. The manufacture of gunpowder is also carried on at Roslin, the works being distributed in the recesses formed by the sudden bends of the river. The Fushiebridge works have been discontinued. Iron foundries exist at Dalkeith, Westfield, Loanhead, Penicuik, Millerhill, and the suburbs of Edinburgh; brick and tile-works at Portobello, Millerhill, Newbattle, Bonnyrigg, and Rosewell; and candle works at

Dalkeith and Loanhead. Leather also is manufactured at Dalkeith.

Besides the Scottish metropolis, the county contains the following towns and villages:—Leith and Granton, both flourishing seaports; Portobello, a watering-place about three miles to the east, Musselburgh, an agricultural and fishing town near the mouth of the Esk; Dalkeith, a market-town and borough of barony; Corstorphine, with a convalescent hospital and an ancient collegiate church containing several tombs of the Forrester family, who became possessors of the fee in 1371; Ratho, erected in 1401 into a principality for the eldest son of the Scottish king; Cramond, formerly a place of much more importance than now; Mid-Calder, with a church of considerable antiquity, adorned with the armorial bearings of the Sandilands family;² West-Calder, Balerno, Currie, Juniper Green, and Colinton, all manufacturing villages; Liberton, deriving its name from the lepers who once were its principal inhabitants; Gilmerton, mainly inhabited by coal-miners and carters; Lasswade, Loanhead, Roslin, and Penicuik.

The population of the entire county in 1871 was 328,379, of whom 153,892 were males and 174,487 females. Excluding the boroughs of Edinburgh, Leith, Portobello, and Musselburgh, the population of the county proper numbered in 1851, 57,843 persons, and in 1871, 74,126, indicating an increase of 28 per cent. within that period. This increase occurs principally in the parishes of West-Calder, Lasswade, Colinton, Dalkeith, and Kirknewton.

Antiquities.—It is believed that Cramond was once a Roman seaport; and various objects of Roman art have been discovered in the vicinity and upwards along the bank of the Almond. On several heights are remains of early military works—the most important being that on Dalmahoy Hill, Braidwood Castle in the parish of Penicuik, and the so-called Castle Greg on the Harburn estate in Mid-Calder parish. "Eirdelhouses" have been discovered at Crichton Mains, at Borthwick Castle, near Middleton House, &c., the first being especially interesting from the fact that some of the stones bore the marks of Roman masonry. There are hut-circles and a hill fort on Kannes Hill, near Ratho; a large tumulus, with three upright stones, at Old Liston; a smaller tumulus at Newbattle; a kistvaen at Carlowrie; and standing stones at Lochend, at Comiston (the Caiy stone), and several other places. The most remarkable of all perhaps is the "Cat Stone," on the Brigs farm near Kirkliston, which, according to an ingenious hypothesis of Sir James Young Simpson, marks the burial place of the grandfather of Hongist and Horsa. (See *Proceedings of the Antiquarian Society of Scotland*, 1855, 1873, 1875.)

The following are among the most interesting of the residential and ecclesiastical buildings in Mid-Lothian, not within the limits of the larger towns and villages. Roslin Chapel, founded by the St Clairs in 1446, is one of the most highly decorated specimens of Gothic architecture in Scotland, and presents a remarkable combination of peculiarities. Roslin Castle, the seat of the St Clairs, is a fine ruin, occupying a peninsular rock on the banks of the Esk, and must have been a very strong position before the days of cannon. Hawthorndon, a little further down the stream, is interesting as the residence in the 17th century of Drummond the poet, as well as for the strange caves in the rock on which it is built. Dalhousie Castle, the seat of the earl of Dalhousie, is a modernized building of castellated style on the banks of the South Esk; and Newbattle Abbey, the seat of the marquis of Lothian, occupies the site of the ancient Cistercian monastery a few miles down the stream. Craigmillar Castle is a fine ruin on a knoll three

¹ From this enumeration the manufactures of the city are excluded.

² See *Proc of Scot Antiq Soc.* 1862.

miles to the south of Edinburgh, which formerly was the residence of the Preston family, and afforded shelter on various occasions to Queen Mary. Borthwick Castle, also a temporary residence of the unfortunate queen, is a double tower on Middleton Burn, still bearing the marks of Cromwell's cannon balls. Crichton Castle, a mile and a quarter to the east, was the residence of the well-known family which produced the celebrated Sir William Crichton, and its ruins show "the builders' various hand." Dalmahoy Castle, near Ratho, is the seat of the earl of Morton, and preserves, besides other valuable antiquities, the only extant copy of the Bible of the Scottish Parliament, and the original warrant for committing Queen Mary to Lochleven. Melville Castle, near Lasswade, the seat of the earl of Melville; Colinton House, the seat of Lord Dunfermline; Calder House, the seat of Lord Torphichen; Ricecarton, belonging to Sir William Gibson Craig, Bart.; and Lauriston Castle, once occupied by John Law of Mississippi notoriety, may also be mentioned. Temple, on the South Esk, was at one time the chief seat of the Knights Templars in Scotland.

The history of the county is of little importance apart from that of the city of Edinburgh. Traces of early Celtic occupation still remain in such names as Inveresk, Alnoud, Leith, Dalry, Dalmahoy, Dalkeith, &c; though by far the greater proportion of the villages, hamlets, and castles have received their present designation from Saxon possessors. The termination *ton* is very frequent. Within the county lie the battlefields of Boroughmuir, where the English were defeated by the earl of Murray in 1334; Pinkie, near Inveresk, where the duke of Somerset inflicted tremendous loss on the Scotch; and Rullion Green, on the eastern slopes of the Pentlands, where the Covenanters were routed by the royal troops under General Dalziel.

EDINBURGH, the ancient capital of Scotland, is situated in the county of Mid-Lothian or Edinburgh, to the south of the Firth of Forth. The Royal Observatory, which is built on the summit of the Calton Hill, in the north-eastern quarter of the city, is in $55^{\circ} 57' 23''$ of N. lat., and $12^{\text{m}} 43^{\circ} 05'$ of time W. long. of the meridian of Greenwich.

The site of Edinburgh is altogether remarkable as that of a large city, and is the chief source of its peculiar characteristics. It occupies a group of hills separated by deep ravines, and is the central feature of a landscape of rare beauty. The county of Mid-Lothian forms towards the south-east a wild hilly district, diversified with fertile cultivated tracts, but, over an extensive area, broken into a rough pastoral country, rising at various points to upwards of 2000 feet above the level of the sea. On the north it is bounded by the Firth of Forth, from the shores of which the ground slopes gradually towards the south till it merges in the range of the Pentland Hills, with its contour diversified by various undulations and abrupt heights. On this irregular ground, and the outlying spurs of the Pentlands, a bold cliff of trap-rock, which rises through the sandstone strata

Environs of Edinburgh.

of the district, appears to have early attracted attention from its capacity for defence. Maitland, the earliest historian of the city, says, "The situation of Edinburgh plainly shows that its origin is owing to the castle;" and from its standing in St Cuthbert's parish, which surrounds the castle rock, he assumes that the first settlement was in the low ground to the north-west. From this a road anciently led up past the Well-House Tower, along the northern slope of the Castle Hill. By this access Queen Mary and other royal visitants rode up to the castle on various public entries, and then returned through the town, by way of the High Street and Canongate, to Holyrood. Symeon of Durham, under the date 854 A.D., includes Edinburgh among the churches and towns of Northumbria within the bishopric of Lindisfarne, and this is supposed to refer to the church of St Cuthbert. But the first erection of the *Magh dun* fortress, or "Maiden Castle," on the summit of the rock, must have tempted the natives of the district to seek the protection of its defences. Hence at an early period a hamlet grew up along the ridge which slopes from the castle rock towards the valley at the base of Salisbury Crags, distinct from the Kirk-town of St Cuthbert.

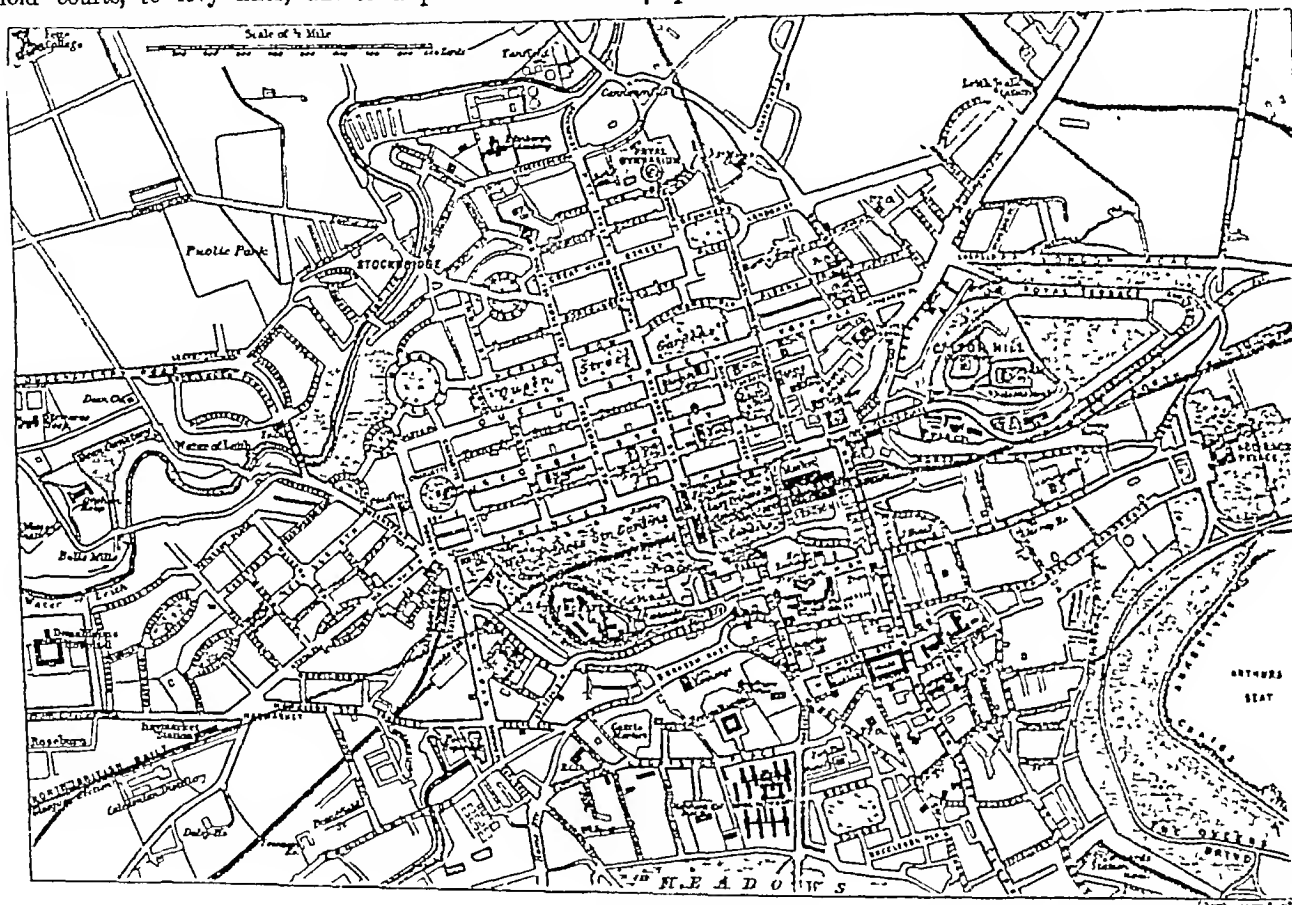

In the reign of Malcolm Canmore the Castle of Edinburgh included a royal palace. There his pious queen, Margaret, the grand-niece of Edward the Confessor, died in 1093. It continued to be a royal residence during the reigns of her three sons, and hence the first rapid growth of the upper town may be referred to the 12th century. The parish church of St Giles is believed to have been erected on its present site in the reign of Alexander I., about 1110, and the huge Norman keep of the castle, built by his younger brother, David I., continued to be known as David's Tower till its destruction in the siege of 1572. Before his accession to the Scottish throne, David I. had been earl of Huntingdon, having acquired that manor and earldom in England by his marriage with Matilda the heiress of Walthoof, earl of Northumberland. He consequently frequented the English court, and became familiar with the military and ecclesiastical architecture introduced by the Anglo-Norman kings; and soon after his accession to the Scottish throne he founded the Abbey of Holyrood, which from an early date received the Scottish court as its guests. But notwithstanding the attractions of the abbey and the neighbouring chase, the royal palace continued for centuries to be within the fortress, and there both the Celtic and Stuart kings frequently resided. Edinburgh was long an exposed frontier town within a territory only ceded to Malcolm II. about 1020; and even under the earlier Stuart kings it was still regarded as a border stronghold. Hence, though the village of Canongate grew up beside the abbey of David I., and Edinburgh was a place of sufficient importance to be reckoned one of the four principal burghs as a judicatory for all commercial matters, nevertheless, even so late as 1450, when it became for the first time a walled town, it did not extend beyond the upper part of the ridge which slopes eastward from the castle rock. But the mural defences of the town were an evidence of wealth and growing prosperity; and no sooner was it surrounded with protecting walls than its rapid increase led to the growth of an extensive suburb beyond their limits.

The other three royal burghs associated with Edinburgh were Stirling, Roxburgh, and Berwick; and their enactments form the earliest existing collected body of the laws of Scotland. But the determination of Edinburgh as the national capital, and as the most frequent scene of parliamentary assemblies, dates from the assassination of James I. in 1436. Of the thirteen Parliaments summoned by that sovereign, only one, the last of them, was held at Edinburgh. But his assassination that same year, in the Blackfriars' monastery at Perth, led to the abrupt transfer of the

court and capital from the Tay to the Forth. The coronation of James II. was celebrated in Holyrood Abbey instead of at Scone; and the widowed queen took up her residence, with the young king, in the Castle of Edinburgh. Of fourteen Parliaments summoned during this reign, only one was held at Perth, five met at Stirling, and all the others at Edinburgh, and, notwithstanding the favour shown for Stirling as a royal residence in the following reign, every one of the Parliaments of James III. was held at Edinburgh. James II. showed special favour to Edinburgh by conferring on it various privileges relating to the holding of fairs and markets, and the levying of customs; and by a royal charter of 1452 he gave it pre-eminence over the other burghs. Further immunities and privileges were conferred on it by James III., and by a precept, known as the Golden Charter, of 1482, he conferred on the provost and magistrates the hereditary office of sheriff, with power to hold courts, to levy fines, and to impose duties on all

merchandise landed at the port of Leith. Those privileges were renewed and extended by various sovereigns, and specially by a general charter granted to the city by James VI. in 1603, the year of his accession to the English throne.

James III. was a great builder; and, in the prosperous era which followed on his son's accession to the throne, the new town of the 15th century spread over the open valley to the south, with the Cowgate as its chief thoroughfare. But the death of James IV. in 1513, along with other disastrous results of the battle of Flodden, brought this era of prosperity to an abrupt close. The citizens hastened to construct a second line of wall, inclosing the Cowgate and the heights beyond, since occupied by the Greyfriars' Church and Heriot's Hospital, but still excluding the Canongate, as pertaining to the Abbey of Holyrood. The new wall long determined the limits of the town. For upwards of two centuries after its erection the requisite

Plan of Edinburgh

accommodation for the increasing population was secured by crowding buildings on every available spot within the protection of the walls, displacing the earlier structures by lofty piles of building within the straightened area, and projecting from them overhanging additions of timber. By those means the northern and southern slopes of the ridge along which the main street of the old town was formed were crowded with the picturesque alleys and closes which contributed so much to the peculiar aspect which the ancient city still retained when in 1808 Scott thus pictured it:—

"Such dusky grandeur clothed the height,
Where the huge castle holds its state,
And all the steep slope down,
Whose ridgy back heaves to the sky,
Piled deep and massy, close and high,
Mine own romantic town."

Within this ancient civic area stand the collegiate church of St Giles—for a time the cathedral of the diocese of Edinburgh,—the Parliament House and law courts, and

the civic Council Chambers. Here also in earlier years of the present century stood the old Tolbooth, or Heart of Mid-Lothian, and other buildings of note, including mansions of the Scottish nobility, and even of royalty. But it forms a mere historic nucleus of the modern city, which for a century past has been extending over the neighbouring heights, northward towards the ancient seaport of Leith, and southward and westward to the lower slopes of the Pentland Hills. The area included within the parliamentary boundary extends to 4179 acres, or 6½ square miles; but, owing to its singularly irregular site, while the lower parts of the city stand little more than 100 feet above the level of the sea, the higher parts rise in some places to 250 feet, and the summit of the castle rock is 383 feet above the sea.¹ Within the same civic

¹ The extensive building operations engaged in by the corporation at the beginning of the century were the main cause of the insolvency of the city in 1833, when the property of the corporation was valued

area, and entirely surrounded and in part encroached on by its streets, is the Calton Hill, occupied by the Royal Astronomical Observatory, the floor of which stands at a height of 319 feet above the sea; and beyond the narrow valley, in which the Canongate and the Palace of Holyrood lie, Arthur's Seat and Salisbury Crags rear their lofty cliffs in boldly picturesque outline, the highest summit rising to the height of

Arms of Edinburgh.

822 feet, and affording a magnificent prospect over land and sea. Bridges connect the different ridges on which the city is built, with crowded thoroughfares underneath. Many of the public buildings occupy lofty terraces, and thereby show to greater advantage than their architectural designs would otherwise secure for them. The valley between the Old and the New Town, and the slopes of the castle rock, are laid out as public gardens; and the Calton Hill and Arthur's Seat furnish promenades and carriage drives of unqualified variety and beauty as the public parks of a large city. Fine white freestone abounds in the immediate neighbourhood, and furnishes abundance of the best building material; while the hard trap-rock, with which the stratified sandstones of the coal formation have been extensively broken up and overlaid, supplies good materials for paving and roadmaking.

Thus on a locality seemingly ill-adapted for the site of a great city, there has gradually arisen one which compares to advantage with the most picturesque and beautiful among the capitals of Europe. Sir David Wilkie came to it in 1799 fresh from a Fifeshire manse, to begin the studies in the Edinburgh school of design which ultimately secured for him his high fame as an artist. When he returned to it in later years, familiar with all that European art had to disclose, he thus gave utterance to his matured impressions:—

"What the tour of Europe was necessary to see elsewhere I now find congregated in this one city. Here are alike the beauties of Prague and of Salzburg; here are the romantic sites of Orvieto and Tivoli; and here is all the magnificence of the adured bays of Genoa and Naples. Here, indeed, to the poetic fancy may be found realized the Roman Capitol and the Grecian Acropolis."

The name of Edinburgh is a memorial of the intrusion of a new people, when, in the beginning of the 7th century, the race of Ida reared the fortress of Edwin's-burgh on the rocky height, and thereby established the Anglian power on the Forth. But this Teutonic invasion was not the first occupation of the site. Camden aimed at identifying it with the *Στρατόπεδον Πρωτόν* of Ptolemy; and although this has been rejected by later Roman antiquaries, the convergence of Roman roads towards the place, the traces of Roman art discovered from time to time within the old civic area, and the evidence of two Roman seaports, at Inveresk and Cramond, both connected with it by roads of Roman structure,—all tend to confirm the idea that Edinburgh was one of the sites occupied by the Roman invaders. On their withdrawal it remained an important stronghold on the southern frontier of the Pictish kingdom. One learned Anglo-Saxon scholar, the Rev. D. H. Haig, in his *Anglo-Saxon Conquest of Britain*, has identified it as the Hill of Agned, the scene of Arthur's victory of Cat Bregon.

For centuries after the founding of the Anglian kingdom of Northumbria, the lowlands extending from the Forth to the Tweed continued to be a debatable land held by uncertain tenure; it was to a large extent settled anew

by Anglo-Saxon and Norman colonists under Malcolm Canmore and his sons. Edinburgh accordingly remained a frontier post beyond the Forth, until it became the capital of the Stuart kings. Then, for the first time, it rose into importance as a town. It shared in their triumphs, and bore the chief brunt in their repeated disasters; and, even after their forfeiture of the crown, some of its most picturesque associations are with the Stuart claimants for the throne of their ancestors. Nevertheless Edinburgh continued till near the close of the 18th century to be circumscribed within the narrow bounds of the ancient city and the burgh of Canongate, with the main street extending along the height of the slope from the Castle to Holyrood Palace, and the Cowgate as the only other thoroughfare admitting of the passage of wheeled carriages. Hence the vehicle in general use was the sedan chair, by means of which the Scottish nobility and gentry paid fashionable visits in the narrow wynds of their ancient capital, and proceeded in full dress to the assemblies and balls, which were conducted with the most aristocratic exclusiveness in an alley on the south side of the High Street, which still bears the name of the Assembly Close.

Beyond the walls of the ancient city lay the burghs of Calton, Easter and Wester Portsburgh, the villages of St Cuthbert's, Montrie's Hill, Broughton, Canonmills, Silvermills, and Deanhaugh—all of which have been successively swallowed up in the extension of the modern city. The ancient seaport of Leith, though a distinct parliamentary burgh, governed by its own magistrates, and electing its own representative to Parliament, has already extended its buildings, at one point at least, so as to conjoin with those of the neighbouring city.

The progress of Edinburgh during the present century has been remarkable in many ways. In 1801 the population, including the Canongate and other extra-mural suburbs, but exclusive of Leith, was 66,544; in 1871 it had risen to 196,979. But the characteristics of the city and its population are peculiar. From an early date the special associations with the national literature have been identified with the ancient capital. Barbour, indeed, the contemporary of Chaucer, was archdeacon of Aberdeen; and the royal author of the *King's Quair* is chiefly associated with Perth; but in the following reign Edinburgh had become the favourite residence of the Scottish kings. One of the foremost charges against James III. was that he preferred the society of artists and musicians to that of the rough barons of his court. Under the patronage of his son, the printing press was first set up at Edinburgh in 1507. At the court of Holyrood, so long as James IV. reigned, the rivalry of rank and genius involved no conflict. Of the three great poets of the reign, Dunbar is believed to have been a grandson of the earl of March; Walter Kennedy was a younger son of the first Lord Kennedy; Gavin Douglas the third son of the earl of Angus; and Dunbar enumerates six or seven other literary contemporaries. In his *Remonstrance to the King*, he notes among the servitors of his royal master glazing-wrights, goldsmiths, lapidaries, apothecaries, painters, and printers; and some of his own poems appear to have been among the first works issued from the Edinburgh press by the Scottish Caxton, Walter Chepman. Gavin Douglas, the author of the *Palace of Honour*, and the translator of Virgil, was provost of the collegiate church of St Giles; and Roul, another literary contemporary named by Dunbar in his *Lament for the Makaris*, is believed to have been provost of the neighbouring collegiate church of Corstorphine. In the following reign Sir David Lindsay was the leader among the literary men of the Scottish capital; and in 1554 his famous *Satire of the Three Estates* was enacted in the presence of the court, at Greenside, a natural amphitheatre on the north-

at £271,658 against a debt of £425,195, which was compounded for by the issue of 3 per cent. bonds of annuity—the loss to the creditors thus amounting to 25 per cent. of their claims.

west side of the Calton Hill, which appears to have been the favourite tilting ground, and general arena for public displays,—including even the burning of heretics and witches.

The names of Knox (died 1572), Buchanan (1582), Alexander Montgomery (1605), Drummond of Hawthornden (1649), Allan Ramsay (1757), Smollett (1771), Fergusson (1774), and Burns (1796), carry on the literary associations of the Scottish capital nearly to the close of the 18th century, when various causes combined to give them a new significance and value. In the later years of the 18th and the beginning of the 19th century the university of Edinburgh was distinguished by teachers who gave it a prominent rank among the European schools of science and letters, while members of the legal faculty disputed with them in friendly rivalry. Gregory (died 1701), the Monros (the elder 1767, the second 1817), Cullen (1790), Black (1799), Playfair (1819), Dugald Stewart (1828), and Leslie (1832), all figure among the professors of the university; while David Hume (1776), Adam Smith (1790), Robertson the historian (1793), Henry Mackenzie (1831), and others of the same literary circle gave ample range to its intellectual triumphs. To this succeeded the era of *Marmion* and *The Lady of the Lake*, followed by the *Waverley Novels*, and *Blackwood's Magazine* and the *Edinburgh Review*, when Scott, Wilson, Brougham, Jeffrey, Cockburn, and Chalmers gave the character to the literary society of Edinburgh which won for it the name of Modern Athens. To this the actual correspondence of its site to that of Athens no doubt also contributed. Various travellers have noted the resemblance between the distant view of Athens from the Ægean sea, and that of Edinburgh from the Firth of Forth. The popular recognition of this unfortunately tempted the citizens to aim at a reproduction of the Parthenon of Athens on the summit of the Calton Hill, in commemoration of Wellington and his brothers in arms, by whom the victory of Waterloo was made the harbinger of peace to Europe. The abortive scheme, as an incompleated project, undesignedly reproduces the ruin of the ancient Acropolis.

Literary taste and culture still characterize Edinburgh society; but—apart from the exceptional influences of pre-eminent genius—the causes which largely contributed to give it so special a character no longer exist. In Scott's early days a journey to London was beset with difficulties, and even dangers; whereas railways have now brought it within a few hours' distance, and Scottish artists and literary men are tempted to forsake Edinburgh for the great centre of all national activities. Nevertheless, the influence of the past survives in many ways. Edinburgh is not a manufacturing city, but retains even now something of the character of the Scottish capital, as the resort of those whose means enable them to enjoy in ease and comfort its social amenities, without indulging in the costly gaieties which a London season involves. The supreme courts of law hold their sittings in Edinburgh, and still retain some of the most characteristic features impressed on them when remodelled by James V. in 1532. The Court of Session has the lord president as its head; and the High Court of Justiciary is presided over by the lord justice-general and the lord justice-clerk. The judges, as senators of the College of Justice, have also the title of lord, not infrequently coupled with that of their landed estate—as Fountainhall, Kaimes, Hales, Monboddo, Woodhouselee, or Colonsay; and the advocates and writers to the signet—as the two leading branches of the Scottish legal profession are styled,—help to give a legal tone to the society of the Scottish capital.

The university, with the medical schools and other educational institutions, have long added to the attractions of Edinburgh. As a school of art it has also required a

special character; and the names of Runciman, Nasmyth, Raeburn, Wilkie, Allan, McCulloch, Watson Gordon, Harvey, and Drummond (without referring to living painters and sculptors) are all familiar, and some of them eminently distinguished in art. A school of design was established at Edinburgh in 1760 by the Honourable Board of Trustees for Manufactures, at which Raeburn, Wilkie, Allan, and other leading Scottish artists, along with many others of less note, obtained their preliminary training. With its aid the application of art to manufacturing design and decoration has received an important stimulus. Steel and wood engraving have also largely benefited by the same facilities; and this in its turn has aided in fostering the printing press as a special branch of trade for which Edinburgh has long been celebrated. In early days the names of Chepman, Millar, Bassandyn, Charteris, Hart, Watson, and Ruddiman figure among its celebrated typographers; and more recent enterprise has added to the reputation of the Edinburgh press.

But although a large unemployed population, in close proximity to a coal-field and to the fertile Lothians, and with the command of the chief seaport of the east of Scotland, gives a stimulus to important industries, the Scottish capital lays no claim to rivalry with Glasgow or Dundee as a manufacturing town. The unique beauty of its site, and the abundance of fine building material, while they have fostered the desire for developing its architectural features have begot a disinclination to encourage such manufactures as would tend to interfere with the amenities of the city. The anxiety with which these are guarded commands the sympathy of all classes of the community. The distinctive contrast between the Old and the New Town is kept ever in view. The predominant character of the former is a seemingly lawless picturesqueness, resulting from the extreme irregularities of the sites occupied by its most prominent buildings on the abrupt slopes of the ridge which is crowned by the ancient fortress. The symmetrical formality of the New Town is all the more effective from the contrast which it thus presents to the older districts of the city. In most of the old historical cities of Europe the stranger recalls the contrast as he proceeds from modern to older districts; but in Edinburgh he can look down on the city from the castle, the Calton Hill, or Arthur Seat, and view the whole spread out like a map before him; or, as he traverses the beautiful terrace of Princes Street, adorned with statues, monuments, and public buildings, he looks across the fine pleasure grounds in the intervening valley to the quaint old town with its still older castle.

The improvements effected on the Old Town during the past forty years, while they have swept away many interesting historical remains, have on the whole resulted in a more effective development of its picturesque features. During the same period the New Town, and the still more recent extensions to the west and south, have been carried out with a careful eye to the general results; and alike in the Old and the New Town the advantageous sites of the chief public buildings largely contribute to their architectural effect.

The Castle—The central feature of Edinburgh is the castle, which includes structures of very diverse dates. The oldest of its buildings, occupying the very summit of the rock, is St Margaret's Chapel, an interesting relic, belonging at latest to the reign of Queen Margaret's youngest son, David I., and by some good authorities believed to be the actual chapel in which the queen of Malcolm Canmore worshipped. Next in interest are the ancient hall and other remains of the royal palace, which form two sides of the quadrangle styled palace yard, and occupy the summit of the rock towards the south. These buildings include the apartments occupied by the regent, Mary de Guise, and

her royal daughter, Queen Mary, and the room in which James VI. of Scotland and I. of England was born. Here also is the Crown Room, in which are deposited the Scottish regalia, or "The Honours of Scotland," as they are called, along with a beautiful sword of state presented to James IV. by Pope Julius II., and the jewels restored to Scotland on the death of Cardinal York, the last of the Stuarts. The arsenal, a modern building on the west side of the castle rock, is capable of storing 30,000 stand of arms. In the armoury a display of arms of various dates is made; and on the Argyll battery, immediately to the south of St Margaret's Chapel, stands a huge piece of ancient artillery, called Mons Meg, of which repeated mention is made in Scottish history.

Holyrood Palace, the venerable abode of Scottish royalty, was originally an abbey of canons regular of the rule of St Augustine, founded by David I. in 1128. The ruined nave of the abbey church still retains portions of the original structure. Conjoined to this is a part of the royal palace erected by James IV. and V., including the apartments occupied by Queen Mary, and the scene of the murder of Rizzio in 1566. The abbey suffered in repeated English invasions. It was sacked and burnt by the earl of Hertford in 1544, and again pillaged and left in ruin by the same invaders in 1547, almost immediately after the accession of Edward VI. to the English throne. In a map of 1544, preserved among the Cotton MSS. in the British Museum, the present north-west tower of the palace is shown standing apart, and only joined to the abbey by a low cloister. Beyond this is an irregular group of buildings, which were replaced at a later date by additions more in accordance with a royal residence. But the whole of this later structure was destroyed by fire, while in occupation by the soldiers of Cromwell, in 1650; and the more modern parts of the present building were commenced during the Protectorate, and completed in the reign of Charles II. by Robert Mylne, in accordance with a design of Sir William Bruce of Kinross. They include the picture gallery, 150 feet in length, famous for its fanciful array of 106 mythical portraits of Scottish kings, the reputed descendants of King Fergus I., but also adorned with a remarkable triptych, painted about 1484, containing portraits of James III. and his queen, Margaret of Denmark, and believed to have formed the altar-piece of the collegiate church of the Holy Trinity, founded by the widowed queen of James II. in 1462, and only demolished in 1848. The picture gallery is interestingly associated with festive scenes during the brief presence of Prince Charles Edward in Edinburgh in 1745; and in it the elections of representative peers for Scotland take place. The exiled Comte d'Artois, afterwards Charles X. of France, had apartments granted for the use of himself and the emigrant nobles of his suite, on their escape from the first French Revolution, and they continued to reside in the palace till August 1799. When driven from the French throne by the revolution of 1830, the same unfortunate prince once more found a home in the ancient palace of the Stuarts. In the interval between these two visits it was graced by the presence of George IV. in 1822; and it has been repeatedly occupied for brief periods by Queen Victoria and the Prince Consort. A beautiful fountain, the design of which is a restoration of the ruined fountain in the quadrangle of Linlithgow Palace, stands in the centre of the outer court of Holyrood, and forms a memorial of the interest evinced by Prince Albert in the ancient Scottish palace.

The Parliament House, in which the later assemblies of the Scottish estates took place, until the dissolution of the Parliament by the Act of Union of 1707, has ever since been set apart as the place of meeting of the supreme courts of law. The great hall, with its fine open-timbered oaken

roof, under which the last Scottish Parliament assembled still stands, and forms the ante-room of the advocates and other practitioners, and of their clients, during the session of the supreme courts. But the surrounding buildings, including the court-rooms, the Advocates' and the Signet Libraries, are all modern additions. The Advocates' Library is the largest and the most valuable library in Scotland. It was founded in 1682, at the instance of Sir George Mackenzie, king's advocate under Charles II., and then dean of the faculty, and has been augmented by important gifts. It is regarded with just pride as the national library, and is one of the five libraries entitled by the Copyright Act to receive a copy of every work printed in Britain. The number of volumes now included in the collection is estimated to amount to 260,000. The Library of the Society of Writers to the Signet contains upwards of 50,000 volumes, and, although more private in its character, it has always been available for research by literary students.

The General Register House for Scotland, which stands at the east end of Princes Street, is an important adjunct to the supreme courts; and, in its ample provisions for the registry and safe-keeping of all deeds and judicial records, it compares favourably with the system in vogue in England. Not only is there adequate accommodation, in fire-proof chambers, for all Scottish title-deeds, entails, contracts, and mortgages, and for general statistics, including births, deaths, and marriages, but there also are deposited all the ancient national records, the full historical value of which is only now beginning to be generally appreciated. The general record department is in charge of the lord clerk register and keeper of the signet, assisted by a deputy clerk register, a deputy keeper of the records, a curator of the historical department, and other officials.

The Royal Institution, a fine structure of the Grecian Doric order, surmounted by a colossal statue of the Queen, executed in stone by Sir John Steell, furnishes official accommodation for the Board of Trustees for Manufactures, and the Board of Fishery, and also for the School of Art and Statue Gallery of the Royal Institution, the Museum of National Antiquities, and the libraries and public meetings of the Royal Society and the Society of Antiquaries of Scotland. This beautiful building is thus made the centre of varied intellectual activity, in artistic culture and design, scientific, historical, and archaeological research, as well as in the practical application of the fine arts, and of the newest disclosures in science, to the manufacturing and trading interests of the whole nation.

Among those the National Museum of Antiquities claims special attention. The Society of Antiquaries of Scotland was founded in the year 1780 by a body of noblemen and gentlemen, who held their first meetings at the house of the earl of Buchan; and almost immediately after its foundation they devoted themselves to the formation of an Archaeological Museum. The history of the early years of the society is a curious commentary on the manners of the Scottish capital a century ago. With the dukes of Montrose and Argyle, the earls of Buchan, Bute, Fife, and Kintore, and many of the leading Scottish gentry among its active members, a suitable hall secured for the meetings of the society in the Cowgate was successively exchanged for others in Webster's Close, and Gornray's Close, Lawnmarket—the reason assigned for abandoning the latter being that the alley was too narrow to allow of the members reaching the society's hall in their sedan chairs. After passing through various vicissitudes, and occupying more than one hall in the New Town, it was found that the collections of the society had attained to a magnitude and value which rendered it no longer possible for a private society to do justice to them. Archaeological investigations,

moreover, have now come to occupy a no less important relation to the researches of science than to the study of history; and in many of the capitals of Europe similar collections are promoted as objects of national importance. Negotiations were accordingly entered into with the Government in 1849 and subsequent years, which resulted in the appropriation of the galleries in the Royal Institution, formerly devoted to the exhibitions of the Royal Scottish Academy, to the reception of the collections of the Society of Antiquaries of Scotland as a National Museum of Antiquities. The council of the society, with the addition of two members of the Board of Trustees as representatives of the Crown, continue to have the charge of the collections, which are open to the public, like the British Museum and other national collections. The museum is specially rich in Scottish antiquities, illustrative alike of prehistoric archæology, of Roman, Celtic, and Teutonic remains, and of mediæval civil and ecclesiastical art; and its native and foreign collections of primitive antiquities are arranged with a view to illustrate modern archæological science, by the comparative classification of numerous examples of primitive flint, stone, and bronze relics, sepulchral pottery, implements and weapons, and of personal ornaments of gold, silver, and bronze. The society publishes its proceedings annually, and from time to time issues its transactions, embodying the more important historical and archæological treatises submitted to its meetings, in the quarto volumes of the *Archæologia Scotica*.

The Royal Society of Edinburgh was incorporated by royal charter in 1783, for the encouragement of philosophical inquiry and scientific research. Its extensive library and other collections are accommodated in the apartments occupied by it in the Royal Institution buildings; and its proceedings and transactions are now voluminous, and embody many important scientific papers.

The Royal Scottish Academy of Painting, Sculpture, and Architecture, was instituted in 1826, and incorporated by royal charter in 1838, on the model of the Royal Academy of London. Subsequent to the completion of the Royal Institution buildings the central range of galleries was appropriated to the annual exhibitions of the Academy; but in August 1850 Prince Albert laid the foundation-stone of the National Gallery, a building exclusively devoted to the promotion of the fine arts in various ways, including the accommodation of the Royal Scottish Academy, and which has also greatly contributed to the architectural beauty of the city. The low valley, or ravine, which separates the Old from the New Town, is not only spanned by the North and Waverley Bridges, but is also crossed midway by a huge earthen viaduct, formed by depositing the materials excavated for the foundation of the houses erected on the neighbouring terrace of Princes Street. This, which long formed an unsightly blemish, was at length utilized for the improvement of the city, as the site of the Royal Institution building. But there still remained in the rear a huge excrescence styled the Earthen Mound, cumbered with temporary buildings, and an eyesore to all who appreciated the amenities of the general view. The property of this as a building site was acquired by the Board of Trustees under an Act of Parliament, which vested it, and the buildings erected thereon, in the Board, subject to the Lords Commissioners of the Treasury; and in 1854 the new galleries were completed. The building is of the Greek Ionic order, thereby pleasantly contrasting with the more massive Doric of the Royal Institution building; and the view of the two, as seen from East Princes Street, grouping together with the Castle, the Free Church College, and the masses of the Old Town buildings rising behind, is singularly striking and effective. The National Gallery provides for the public display of a fine national

collection of paintings and sculpture, acquired by purchase and bequest, for the annual exhibitions of the Royal Scottish Academy, and for the Life Academy and other schools specially designed for the advancement of the fine arts in Scotland.

The University of Edinburgh was founded in 1582, by a royal charter granted by King James VI., and its rights, immunities, and privileges have been remodelled, ratified, and extended at various subsequent periods. In 1621 an Act of the Scottish Parliament ratified to the university of Edinburgh all rights and privileges enjoyed by other universities in the kingdom, and those were renewed under fresh guarantees in the Treaty of Union between England and Scotland, and in the Act of Security. Important changes have since been made on the constitution of the university by an Act of the British Parliament passed in 1858. But while the college, as such, bears the name of the College of King James, or King's College, and James VI. is spoken of as its founder, it originated in the liberality of the citizens of Edinburgh. William Little of Craigmillar, and his brother Clement Little, advocate, along with James Lawson, the colleague and successor of Knox, may justly be regarded as the true founders of the college. In 1580 Clement Little gave all his books, amounting to 300 volumes, for the beginning of a library, and this was augmented by other valuable benefactions, one of the most interesting of which was the library of Drummond of Hawthornden, the friend of Ben Jonson—a collection rich in choice specimens of our rarer early literature. The University Library now contains about 139,000 printed volumes, and above 700 volumes of MSS., many of which are of great interest and value.

The buildings of the university occupy the site of the ancient collegiate church of St Mary in the Field, or the Kirk of Field, as it was familiarly termed. The present structure is a classical building, inclosing an extensive quadrangle. The older parts of it, including the east front, are from the design of Mr Robert Adam; but his plans were revised and modified with great taste by Mr W. H. Playfair, with a view to the completion of the building; and the whole is now finished, with the exception of a cupola designed to surmount the east front, for which the requisite funds have been bequeathed to the university. This edifice affords accommodation for the lecture rooms in the four faculties of arts, law, medicine, and theology, and for the museums and library. But although entirely reconstructed on a greatly enlarged scale during the present century, they have already proved to be inadequate for the requirements of this celebrated school of science and letters; and extensive new buildings are now in progress at Teviot Row, designed to accommodate the departments of science and medicine, and to leave the older building exclusively for the departments of arts, law, and theology. The new buildings will accordingly include a university convocation hall, class-rooms, laboratories, dissecting rooms, and museums.

In connection with this, the *Royal Infirmary* is also in progress of completion, on a new site, and on a greatly enlarged scale, with operating theatre and other requirements in connection with the medical school, and with all the most modern improvements in the arrangement and construction of hospitals. For this a site nearly adjoining to that of the new college buildings, previously occupied by George Watson's Hospital, has been selected. It embraces a large area between the Heriot's Hospital grounds and the Meadows, and separated by the fine avenue of the Meadow Walk from the new medical schools. By this means the important requisites of free air and the immediate vicinity of extensive pleasure grounds are secured, and thus the primary object of the infirmary as a benevolent institution for ministering to the wants of those afflicted with disease,

or suffering from injuries, is efficiently combined with its indispensable uses as a school for clinical instruction and practical training in the healing art.

The Royal Botanical Garden is another important adjunct to the university as a school of science. The professor of botany is regius keeper of the garden; but its special requirements necessitate its removal from the crowded centre of the city. It has accordingly undergone four successive changes of site since its foundation in 1670 by Sir Andrew Balfour and Sir Robert Sibbald. It now occupies a fine area of 27 acres on the north side of the city, in Inverleith Row. This is carefully laid out with a special view to botanical instruction. It includes a herbarium and palm houses, with an extensive range of hot-houses, a museum of economic botany, a lecture room, and other requisites for the students of botany who attend here the lectures of the professor during the summer term.

The Royal Observatory, which has already been referred to as one of the architectural adornments of the Calton Hill, also constitutes an important adjunct to the university. The astronomer royal for Scotland holds along with that office the professorship of practical astronomy.

Museum of Science and Art.—One other important institution of practical instruction, in intimate connection with the university, is the Museum of Science and Art, situated immediately to the west of the university building, and in direct communication with it. The first keeper of the museum, Dr George Wilson, was also professor of technology in the university, but the chair has not been filled since his death, though his successor in the charge of the museum delivers lectures from time to time in the large lecture room in the east wing of the building, which is capable of accommodating about 800 sitters. The Museum of Science and Art embraces not only the objects of science included in the departments of geology, mineralogy, palæontology, and natural history, as well as other allied sciences, but also of industrial art, and of the raw productions of commerce, illustrative of nearly all the chief manufactures of Great Britain, and of many foreign countries.

Royal College of Surgeons.—The museum and lecture rooms of the Royal College of Surgeons are accommodated in a handsome classical building in Nicolson Street, in the immediate vicinity of the university buildings. The College of Surgeons is an ancient corporate body, with a charter of the year 1505, and exercises the powers of instructing in surgery and of giving degrees. Its graduates also give lectures on the various branches of medicine and science requisite for the degree of doctor of medicine, and those extra-academical courses are recognized, under certain restrictions, by the university court, as qualifying for the degree. The museum contains a valuable collection of anatomical and surgical preparations adapted to the advancement of the study of surgical science.

Royal College of Physicians.—The Royal College of Physicians is another learned corporate body, organized as such, with special privileges by a charter of incorporation granted to them by Charles II. in 1681. The meetings of the body take place in their hall, a handsome building on the terrace overlooking the Queen Street Gardens, where they have a valuable library and a museum of materia medica. But the college as a body takes no part in the educational work of the university.

The three older Scottish universities of St Andrews, Glasgow, and Aberdeen were all founded in the 15th century, by the authority of papal bulls, and derived their original endowments chiefly from the liberality of influential ecclesiastics, who had large revenues and church property at their disposal. They originated a part of that grand conception of the 15th century, which aimed at organizing the learning of the age into local branches of one university system, embracing the whole scholarship of Christendom, and recognizing

the graduates of all universities as members of one corporate brotherhood, co-extensive with the Christian world. The Scottish universities still differ from those of Oxford and Cambridge in perpetuating some curious relics of this cosmopolitan university system.

The first conception of the University of Edinburgh is also due to a learned Scottish ecclesiastic, Robert Reid, bishop of Orkney, a favourite counsellor of James V., who died at Dieppe in 1558,—as was believed from poison,—when on his way home, after fulfilling his duties as one of the commissioners for the marriage of the Queen of Scots to the Dauphin of France. He left a bequest of 8000 merks towards the founding of a college at Edinburgh, and is stated by the historian of the family of Sutherland to have destined a much larger sum for the same purpose, but it was diverted by the earl of Morton to his own use. The above-named bequest was only recovered after long delay, when, in 1581, it was appropriated to the purchase, from the provost of the Kirk of Field, of the grounds now occupied by the university buildings. The circumstances attendant on the death of this first benefactor of the University remind us of the ecclesiastical changes already in progress in the 16th century. The actual foundation of the University of Edinburgh dated subsequent to the Reformation; and it is honourably distinguished among the national universities of Great Britain as the creation of the citizens themselves.

The Royal Charter granted by James VI in 1582 contemplates a university on a wide basis, with the conditions necessary for liberal study, and arrangements suited to the progress of modern science; and it is wonderful how much has been accomplished in spite of the meagreness of the whole endowment. By the Universities (Scotland) Act of 1858, provision is made for the better government and discipline of the Scottish universities, and that of Edinburgh was materially affected by its operations. The entire origin of the university had placed the patronage of the chairs, and the supreme control of the university, to a very considerable extent in the hands of the city corporation. The administration of the responsible duties thus devolving on the town council reflects, on the whole, great credit on the city, and its exercise of the patronage of university chairs was abundantly justified by the high rank attained by the university under the distinguished professors selected by it. But the university had long outgrown the healthful operation of such anomalous relations, and by the new Act, it has been remodelled as a corporation, consisting of a chancellor, vice-chancellor, rector, principal, professors, registered graduates and alumni, and matriculated students. The chancellor is elected for life by the general council, of which he is head, and the rights of the city as the original founder of the university have been recognized by giving to the town council the election of four of the seven curators, with whom rests the appointment of the principal, the sole patronage of seventeen of the chairs, and a share in other appointments. For further details see UNIVERSITIES.

New College.—One of the proceedings consequent on the disruption of the Church of Scotland in 1843, and the formation of the Free Church, was the establishment of New College at Edinburgh, in connection with that church. As originally projected, it was designed to include scientific and literary as well as theological chairs. Since then, however, this and the other colleges of the Free Church of Scotland, established at Aberdeen and Glasgow, have assumed the more limited character of purely theological colleges—though in that of Edinburgh a chair of natural science is still retained. New College Buildings, designed in the pointed style of the 16th century, are erected on the site of the palace of Mary de Guise, and include a hall for the general assembly, or supreme court of the church. They occupy a prominent site at the head of the Mound, immediately in the rear of the National Gallery; and the two central towers, with a lower one in the same style, attached to the church at the north-east angle, contribute to give elevation to the facade which has been aptly designed to harmonize with the lofty surrounding buildings of the Old Town.

The United Presbyterian Church has also its theological hall for the training of its ministers. The building hitherto occupied for the accommodation of the students, and also for the meetings of its church courts, is situated in Queen Street; but in September 1877 the New Edinburgh Theatre, in Castle Terrace, was purchased with the view of being converted to those uses.

Literary Institutions.—Next door to the United Presbyterian premises in Queen Street is the Philosophical

Institution, of which Mr Thomas Carlyle is president. The lending library of this institution is extensive and valuable, and its annual winter courses of lectures are of a high character, and command great popular interest. The Edinburgh Literary Institute, formed on a nearly similar basis, has its building in South Clerk Street, in the southern part of the city.

Schools—The public seminaries of Edinburgh, including the hospitals and other charitable foundations chiefly directed to the training and education of youth, are upon a very liberal scale. The High School of the burgh dates its existence from an early period in the 16th century. The Burgh Record, under date March 12, 1554, contains an order for the building of the grammar school on the east side of the Kirk of Field Wynd. At a later date, and down to the present century, it occupied the site of the Blackfriars' monastery founded by Alexander II. in 1230. But in the year 1825 the foundation stone was laid of the beautiful classical building which now occupies a prominent site on the southern slope of the Calton Hill. It was originally, and till a comparatively recent date, a purely classical school; but it now furnishes systematic instruction in all the departments of a liberal and commercial education, including the ancient and modern languages, the natural sciences, mathematics, &c.

The Edinburgh Academy, which was established in 1824, and incorporated by royal charter of George IV., is a proprietary school under the superintendence of a board of directors elected by the subscribers. It is arranged into two divisions, the classical and the modern school, for the senior classes. It has established a high character for its classical training, and has already taken an honourable rank among the public schools of Great Britain, by the distinctions achieved by its pupils both at the English and Scottish universities.

Charitable Foundations—Foremost among the charitable foundations for the education and training of youth is George Heriot's Hospital, founded by the jeweller of James VI of Scotland and I. of England, who at his death in 1624 left his estate in trust to the magistrates and ministers of Edinburgh for the maintenance and education of poor fatherless sons of freemen of the city. The building erected for the purposes of the charity is a noble quadrangular edifice, enriched with the elaborate details of the transitional style of domestic architecture of the earlier Stuart kings of England. It occupies a commanding site on the summit of a ridge known of old as the High Riggs, lying between the Grassmarket and the Meadows, and forms a striking feature in the view of the city from various points. 180 boys are maintained on the foundation, 120 resident, and 60 non-resident. Those among them who give proof of diligence and ability are afterwards maintained during a full course of four years at the university; and those who are apprenticed to trades are also provided with funds for five years, amounting in all to £50 sterling, with an additional £5 on proof of good behaviour at the close.

The popular character of Heriot's Hospital, and the effective architecture of its building, have largely influenced the disposition of later charitable bequests in Edinburgh, somewhat to the detriment of the university. Following the example of the jeweller of King James, successive benefactors have founded George Watson's Hospital, the Merchant Maiden Hospital, the Trades' Maiden Hospital, the Orphans', John Watson's, Donaldson's, and Stewart's hospitals—all more or less modelled on the original foundation. Several of their buildings are also possessed of considerable architectural beauty, foremost among which is Donaldson's Hospital, the founder of which amassed a large fortune as a printer, and bequeathed nearly the whole of it in trust for the erection and endowment of a hospital for

the maintenance of poor boys and girls. The trustees have taken advantage of the liberty of choice permissible under such terms to select one-half of the children admitted to the hospital from the class of the deaf and dumb. The building has accommodation for 300 children. In 1877 it contained 214, of whom 120 were boys and 94 girls. Of those 70 of the former and 45 of the latter were deaf and dumb. Experience has thus far tended to show that the constant intercourse between the deaf mutes and their more fortunate companions exercises a beneficial influence on both.

George Watson's Hospital, founded by the bequest of another citizen in 1738, and the Merchant Maiden Hospital, founded so early as 1605, were designed to extend to the sons and daughters of merchants of Edinburgh similar advantages to those which the Heriot's Hospital secured for burghesses' sons. The Trades' Maiden Hospital provided for burghesses' daughters, and John Watson's, Daniel Stewart's, and other similar institutions provided in like manner for the maintenance and education of poor children of various classes. But the multiplication of such charities threatened to outgrow the legitimate wants of the community, and needlessly to withdraw many children from the healthful influences of home training. Hence a growing feeling of the abuses of the system, at the very time when the revenues of Heriot's Hospital were greatly increased in consequence of the extension of the New Town over its lands, at length led to an application to Parliament for power to modify the disposition of the surplus revenue. By the Act thus obtained the governors of that institution were empowered to expend such surplus funds in erecting and maintaining elementary schools for the free education of poor children of deceased burghesses and freemen, and generally of the children of poor citizens of Edinburgh. There are now eighteen of these Heriot foundation schools, in different parts of the city, divided into the two classes of juvenile and infant schools, giving free education, and, in certain cases of extreme poverty, also a sum of money in lieu of maintenance, to 4400 boys and girls.

The example thus set has been followed by the governing bodies of other similar institutions. The Merchant Company, as trustees of the George Watson's, Merchant Maiden, Gillespie's, and Stewart's charities, taking advantage of powers given by the Endowed Institutions (Scotland) Act, obtained power to convert the George Watson's Hospital into a school; and since then, they have sold the building and grounds to the corporation of the Royal Infirmary, and the New Infirmary is now in progress on the site. The Edinburgh Merchant Company's Schools now include the George Watson's College Schools, in which ample provision is made for furnishing a liberal education for boys, qualifying them for commercial or professional life, for the civil service, and for entering the university. Bursaries are also offered for competition, which secure a free enjoyment of the entire course of studies to the successful competitors, and furnish the sum of £25 annually, for four years, after leaving the schools. A similar institution provides corresponding advantages for girls; and the Edinburgh Educational Institution, or Ladies' College, in like manner furnishes a high-class education in the ancient and modern languages, mathematics, the natural sciences, and in music and other more strictly feminine accomplishments; and bursaries and other prizes, of like value to those offered for competition in the College Schools, are placed within reach of the ablest and most diligent female students.

Experience has, therefore, amply confirmed the wisdom of the course thus pursued in the readaptation of this class of charities to the wants of the age; and the example of Edinburgh is likely to influence other cities where similar endowments are, in some cases at least, very partially turned to useful account.

Edinburgh is otherwise well provided with both public and private schools, to which pupils resort, not only from many parts of the kingdom, but from the colonies. The Fettes College was apparently designed by the terms of the will of its founder, Sir William Fettes, to correspond very nearly to Heriot's Hospital. But the trustees have so far modified that idea as to establish a college for boys modelled after the great public schools of England, and designed to furnish a liberal education in the fullest sense of the term. The college building which has been erected at Comely Bank, the estate of the founder, on the north side of Edinburgh, is a structure of an imposing and stately character in the semi-Gothic style of architecture prevalent both in France and Scotland in the 16th century.

The Church of Scotland Training College, the Free Church Normal School, Merchiston Academy, occupying

the antique tower of Napier, famous as the inventor of logarithms, and the Watt Institution and School of Arts, all merit notice among the more important educational institutions; and under the Edinburgh School Board efficient schools are now in operation in various districts of the city, mostly lying beyond the range of the Heriot's schools.

Charities.—Among the public charities of the city the Trinity Hospital, no longer maintained as a hospital with resident pensioners, now expends its income in pensions of from £10 to £20, to 172 poor burgesses, their wives, or children, not under the age of fifty years. The benevolent branch of the Gillespie's Hospital endowment is similarly administered. The Chalmers' Hospital, founded by George Chalmers in 1836, destined for the reception of the sick and hurt, stands on the southern slope of Lauriston, overlooking the Meadows, and at no great distance from the New Royal Infirmary, to which it is a useful adjunct. In addition to those, it may suffice to name the Convalescent House—where, in a pleasant country home near Corstorphine, the convalescents of the Infirmary are transferred from the surgical or fever wards of that hospital to healthful fresh air,—the Royal Hospital for Sick Children, the Home for Crippled Children, the Hospital for Incurables, the Royal Maternity Hospital, along with other kindred institutions. The Royal Asylum for the Insane is at Morningside, on the southern outskirts of the city; and the Royal Blind Asylum, and the Deaf and Dumb Benevolent Society, each provide for the special classes indicated by their names.

Prisons.—The different city prisons are grouped together on the southern terrace of the Calton Hill, styled of old the Dow Craig, so as to form a very striking feature in the general view of the city from various points. They are constructed in a semi-castellated style; and the house of the governor of the jail, built on the summit of a rock overlooking the whole, and on the very edge of a bold perpendicular cliff, looks not unlike one of the old castles familiar to the voyager on the Rhine.

The General Post-Office is the central office for Scotland, alike for postal and telegraphic service, and the building devoted to those purposes is a large and effective structure in the Italian style of architecture, at the east end of Princes Street, directly opposite to the Register Office.

General Assembly of the Church of Scotland.—During the establishment of Episcopacy in Scotland, Edinburgh was the seat of a bishop, and the ancient collegiate church of St Giles rose to the dignity of a cathedral. The annual meeting of the General Assembly of the Church of Scotland at Edinburgh is now the grand public manifestation of the predominance of Presbyterianism as the national church. Annually in the month of May a nobleman, commissioned to act as the representative of the Queen, takes up his abode at the Palace of Holyrood, and proceeds from thence in state to the High Church, and thence to the Assembly Hall on the Castle Hill, as the lord high commissioner to the General Assembly of the national church. The lord provost and magistrates loyally offer to him the keys of the city. Levees, receptions, and state dinners revive in some degree the ancient glories of Holyrood; and, as the General Assembly of the Free Church and the Synod of the United Presbyterian Church are usually held at the same time, the streets of Edinburgh present a singular aspect to a stranger.

Places of Worship.—The buildings set apart as places of worship by the various denominations include 30 belonging to the Church of Scotland, 29 to the Free Church, 23 to the United Presbyterian Church, 14 to the Episcopal Church, and about 30 others to different religious denominations, including a Jewish synagogue.

St Giles's Church.—Among the buildings dedicated to the worship of the different denominations, the ancient collegiate church of St Giles is the most important, alike in its architecture and its historical associations. The Regent Murray, the marquis of Montrose, and Napier of Merchiston are distinguished among the eminent men interred in the ancient church, by monuments marking their tombs. The choir, which has recently been cleared of encumbering galleries, and tastefully fitted up with oaken stalls, and a fine carved pulpit of Caen-stone, is a beautiful example of the ecclesiastical architecture of the 15th century; and the fine Gothic crown which surmounts the central tower forms one of the most characteristic features in every view of the city. The domes, towers, and spires of the various churches add to the general effect of the city, and in some cases they even present an imposing aspect from their elevated and commanding sites. But none of them is of sufficient importance to invite notice for any special architectural beauty, though several are works of merit. By the bequest of Miss Walker of Coates and Drumshough, who died in 1871, funds have been set apart for the erection of a cathedral for the use of the Scottish Episcopal Church. The plans have been prepared by Sir G. Gilbert Scott, in the Early Pointed style of the 14th century, and include a nave, choir, transepts, and chapter-house. If completed according to the approved design, it will be the largest and finest church erected in Scotland, if not in Britain, since the Reformation.

Monuments.—The monuments and statues which adorn the city are of a peculiar character, and contribute to the singular aspect which Edinburgh presents to the eye of a stranger. The fame of Sir George Mackenzie, David Hume, Dugald Stewart, Playfair, Burns, and Scott is commemorated in the case of each by an effective monumental structure dedicated to his memory. Of these the most remarkable is the monument erected by public subscription in memory of Sir Walter Scott, which stands in the eastern division of the Princes Street Gardens. The design, which was furnished by a young architect, Mr G. W. Kemp, is that of a spiral Gothic cross, of great elegance both in outline and in details. A marble statue of Scott, by Sir John Steell, is placed under the central canopy; and the principal niches are occupied by figures of characters in Scott's writings. The Nelson monument, a lofty castellated turret which crowns the highest cliff of the Calton Hill, though of questionable architectural taste, is a striking feature in the general view of the city; and the Melville monument, a graceful and well-proportioned column 136 feet in height, surmounted by a colossal statue of Viscount Melville, first lord of the admiralty under Pitt, rises from the centre of St Andrew Square, and terminates the eastern vista of George Street, with a reproduction, in its proportions and general outline, of the celebrated Trajan column at Rome. Distant half a mile from this, at the west end of George Street, Charlotte Square furnishes a corresponding site for the monument of Prince Albert, from the design of Sir John Steell. A central pedestal, which sustains the equestrian statue of the Prince Consort, has at each of the four angles at its base a group of figures representing different classes of the community paying honour to him; and bas-reliefs, executed, like the statues, in bronze, illustrate characteristic incidents in the Prince's career. George Street is further adorned at the intersection of two of the intermediate streets between St Andrew and Charlotte Squares, with colossal bronze statues by Chantrey of George IV. and Pitt. The beautiful garden terrace of Princes Street, on which the Scott monument stands, also affords appropriate sites for the statues of Allan Ramsay, John Wilson, and other distinguished Scotchmen; at other prominent points in

the Old and New Towns are equestrian statues of Charles II., the duke of Wellington, and John, fourth earl of Hopetoun, and also statues of the duke of York, Lord Melville, &c. The monument to the poet Burns, erected on a prominent site on the southern terrace of the Calton Hill, is in the style of a Greek peripteral temple inclosing a cella designed to form the shrine of a fine marble statue of the poet executed by Flaxman. But it proved to be too confined to afford a satisfactory view of the statue. This has accordingly been replaced by a bust from the chisel of Brodie; and the statue, after being placed for a time in the university library, now forms a prominent feature among the works of sculpture in the National Gallery.

Manufactures.—The principal manufactures may be classed under the following respective heads:—(1) Printing, lithographing, engraving, bookbinding, and typefounding; (2) brewing, distilling, coopering, and manufacture of aerated waters; (3) furniture work, paperhanging, and coach-building; (4) india-rubber work; (5) machinery and brassfounding; (6) tanning; (7) glass work; (8) confectionery.

The city is supplied with water from various extensive reservoirs formed in the valleys of the Logan Water, the Bavelaw Burn, and the North Esk, in the Pentland Hills, lying to the south of the city. A bold project was started in 1872 for securing an inexhaustible supply by bringing in the water from St Mary's Loch, a beautiful lake about three miles in length, at the head of the Vale of the Yarrow, in Selkirkshire, but the plan met with considerable opposition, and was abandoned for a less comprehensive measure, sanctioned by Parliament in 1874, whereby additional reservoirs have been constructed in the neighbouring valleys, and an adequate supply of water secured for the growing requirements of the city.

The population of the parliamentary borough of Edinburgh amounted in 1831 to 136,294, in 1851 to 160,302, and in 1871 to 196,979 (89,245 males and 107,734 females). In 1877 the population was estimated at 218,729; and the annual value of real property was £1,538,738. The city returns 2 members to parliament, and its corporation consists of a lord provost, 6 bailies, a convener of the trades, a dean of guild, and 32 councillors.

Reference may be made to W. Maitland's *History of Edinburgh* (1753), Arnot's *History of Edinburgh* (1789), R. Chambers's *Traditions of Edinburgh* (1824), and D. Wilson's *Memoirs of Edinburgh in the Olden Time* (1846-48). (D. W.)

EDMUND, St (c. 1190-1240). Edmund Rich, archbishop of Canterbury, was born about the close of the 12th century, at Abingdon, then the seat of a great Benedictine convent. He was one of six children. His father was a rich trader and man of the world, his mother a pious woman, who carried out remorselessly the ascetic conception of a religious life. She fasted much and slept little, wore a hair chemise and iron stays, and made her household so uncomfortable by her arrangements that her husband, with her consent, retired to a monastery at Eynesham, as likely to be a more enjoyable home. The story of Edmund's birth and early years is strewn with marvel and miracle. Trained by his mother, he caught her ascetic spirit, and became a willing imitator of her self-tormenting ways. At the age of twelve he was sent to a school at Oxford, where he studied diligently, but continued his ascetic exercises. Naturally susceptible in a high degree to the charm of beauty, he nevertheless vowed a vow of celibacy, and espoused himself to the Blessed Virgin Mary. At Oxford he was prostrated by a brain fever, his mother attended him, and by her desire he received the clerical tonsure. Shortly after, his father apparently being dead, he was sent to Paris to study at the university. He was

called home to attend his mother on her death-bed; and during the next twelve months he lived in retirement in the convent of Merton, in Surrey. He then returned to Oxford, and at once took an honourable place among the teachers of the university, which he retained for some years. He is distinguished as one of the scholars who introduced the study of Aristotle, and he heartily co-operated with those who were striving to recover for Oxford the popularity and prosperity as a place of study which it had recently lost, in consequence of a disturbance (1209) between town and gown, and the migration of students and masters in very large numbers. Edmund ultimately resolved to devote himself to theology, was ordained priest, and took his degree in divinity. "He is the first of our archbishops," says Dean Hook, "to whose name we find the title of S.T.P. attached—the first doctor of divinity." About 1222 he was appointed treasurer of Salisbury Cathedral, and in this office, which he held about eleven years, and to which the prebend of Calne was attached, he endeared himself alike to rich and poor. In 1227 Dr Edmund was one of the preachers of the sixth crusade. In 1233 he was elected to the vacant primacy. Three elections had previously been made by the chapter, which the Pope for various reasons had refused to confirm; and thus, the fourth, was made by the Pope's suggestion, as a compromise acceptable to "Pope, king, and monks," says Fuller, "three cords seldom twisted in the same cable." The *pallium* was sent to England without waiting for the decision of the chapter. The position of the primate was at that time one of peculiar difficulty, and it was with unfeigned reluctance that Edmund accepted it,—feeling, says Lingard, "that the timidity of his conscience would not suffer him to acquiesce in the disorders of the age, and that the gentleness of his temper did not fit him for the stern office of a reformer." The new archbishop attached himself and steadfastly adhered to the national party, whose great object was to insure the independence of the kingdom, the maintenance of the Great Charter, and the exclusion of foreigners from civil and ecclesiastical offices. Early in 1234, before his consecration, he convened a council at Westminster, by which a remonstrance was addressed to the king, requiring him, on pain of the censures of the church, to dismiss his foreign councillors, especially Peter des Roches, bishop of Winchester, through whose influence the strongholds of the kingdom were then in the hands of foreign mercenaries. The consecration of the archbishop was celebrated at Canterbury on the 2d April 1234, and the king was present with all his court. One week later the primate held a second council, and was commissioned by it to threaten the king with excommunication if he did not comply with the terms of the former council. This measure was effectual. The archbishop was then sent into Wales to negotiate a peace with the Prince Llewelyn. In May he held a council at Gloucester, and here was accomplished a temporary reconciliation between the king and the people. In January 1236 the primate had the costly privilege of a royal visit, Henry III. going to Canterbury to await the coming of his bride-elect, Eleanor of Provence, and on the 14th the marriage ceremony was performed by the archbishop. A few days later he officiated at the coronation of the queen. But the hopeless divergence of aims between the king and the archbishop, and the inflexible courage and decision of the latter, induced Henry to apply secretly to the Pope, Gregory IX., to send a legate to reside in England, whose authority might nullify that of the archbishop. Meanwhile, the latter issued, in 1236, his constitutions, which are of no little interest on account of the indications they furnish of the state of the church and of general society. The picture is not a flattering one. In 1237 arrived the legate, Cardinal Otho, who at once won

his way into the royal favour. In November he held a council at St Paul's, but failed to carry his main points against the opposition of the clergy. He stood high, however, with the king, and used or abused his prerogatives for effecting his own purposes. Archbishop Edmund now found himself in opposition to both the king and the Pope; and his position was rendered still more difficult by his excommunication of Simon de Montfort and his bride Eleonor, sister of the king, whose marriage after having taken a vow of perpetual widowhood he felt bound to condemn. In 1238, with a view to obtaining the support of the Pope for his project of monastic reform, Edmund went to Rome. But in this mission he failed. Not only was his purpose frustrated, but he was treated with marked insult by the Pope; and he returned to England sad at heart and burdened with pecuniary difficulties. He soon found that he was reduced to a cipher; he saw the Papal exactions continually growing—"vexed," says Fuller, "at the polling and peeling of the English people"—and saw that the legate's great object was to crush him. In 1240, therefore, he left England, and took up his abode at the abbey of Pontigny, in France, where Thomas Becket and Stephen Langton had previously found an asylum. At his landing he was met by the queen of France, who brought her sons, among them (St) Louis, to receive his blessing. His health was now broken down, and he "sighed out the remainder of his life" in quiet retirement, broken only by occasional preaching. Becoming weaker and weaker, he removed, for the sake of a better climate, to the priory of Soissy, and there he died, November 16, 1240. His tomb, within a year, began to be famous for miracles; and in 1246, after much resistance on the part of the Pope, the archbishop, the staunch foe of Papal extortions, was canonized. He left a work entitled *Speculum Ecclesie*, which he appears to have completed at Pontigny.

Two contemporary biographies of St Edmund are extant, one by his brother Robert Rich, the other by Bertrand, prior of Pontigny, the usual admixture of miraculous and incredible details being found in their accounts. (W. L. R. C.)

EDMUND, or EADMUND (840-870), the last of the kings of East Anglia, was born in 840. He was chosen by Offa as his successor when that king resigned and retired as a penitent to Rome. "The just and holy man"—so Simon Durham describes Edmund—began his reign over the East Angles in 855, and ruled peacefully and uneventfully till his kingdom was invaded by the Danes in 870, when in a battle with Ingvar he was defeated and taken prisoner. The Anglo-Saxon Chronicle says: "The same winter King Edmund fought against them, and the Danes got the victory and slew the king, and subdued all the land, and destroyed all the minsters which they came to." Abbo of Fleury, who writes a life of Edmund, relates the story of his death on the authority of Dunstan, who heard it from the lips of Edmund's sword-bearer. The Danes sent messengers to Edmund, who was dwelling at Hagilsdon (near the present Hoxne), upon the river Waveney, offering to allow him to reign under them on condition that he abjured his religion and divided with them his treasures. Edmund refused these conditions, and being taken prisoner, was bound to a tree, and, after being scourged with whips and pierced with arrows, was finally beheaded. The manner of his death raised him to a place in the roll of martyrs and saints; and on the spot where his head is said to have been miraculously discovered a church was erected, which was succeeded by one of the richest monasteries of England, that of Bury St Edmunds. Here the remains of Edmund are said to have been interred.

EDMUND, or EADMUND I. (ÆTHELING), (922-946), king of the Mercians and West Saxons, was the son of Edward the Elder, and succeeded his brother Athelstan in 941.

being then, it is said, only eighteen years of age, but having already gained the esteem of the people by his courage shown three years before at the battle of Brunanburh. When he succeeded his famous brother, the Northumbrians, judging the opportunity favourable, brought over Anlaf from Ireland, and set him up as their king. The Danes of the kingdom joined them, and the result of the campaign was that Edmund was compelled to make a treaty, by which he ceded a large portion of his territory to his enemy. Two years afterwards, however, on the death of Anlaf, he not only freed his kingdom, but also subdued the Britons of Cumbria or Cumberland, and bestowed their lands on Malcolm I. of Scotland, on condition of his co-operating with him in military service. On the 26th May 946 an outlaw named Leof had slipped into the banqueting-hall of Edmund, who was celebrating the festival of St Augustine at Fucklechurh in Gloucester, and the king in sudden anger, or because he suspected his designs, endeavoured to remove him, whereupon the outlaw plunged a dagger into his bosom and killed him.

EDMUND, or EADMUND II., (989-1016), son of Ethelred, and the last of the line of West Saxon kings, called on account of his boldness and great strength Ironside, was, on the death of Ethelred the Unready, in April 1016, proclaimed king by the citizens of London and such of the Witan as were in the city. At that very time Canute the Dane was preparing an expedition against London, and he was proclaimed king by the Witan of England, which met at Southampton. In command of a magnificent fleet he anchored before London, and by cutting a ditch round that part of the city not washed by the Thames, completely surrounded it; but the citizens, fighting with great valour, repulsed all his attacks. Meanwhile Edmund was acknowledged by the West Saxons, who flocked from every quarter to his standard; and determining to make a diversion in favour of London, he met and defeated the enemy at Pen, near Gillingham, in Dorsetshire. Canute was forced to raise the siege of London, and encountering Edmund at Scedstau, in Wilts, would have been signally defeated, had not the traitor ealdorman Edric raised the head of a fallen thane which resembled that of the king, and called to the Saxons to flee, for their king was dead. Edmund, who was on the top of a hill, saved his subjects from flight by taking off his visor and showing his countenance; but from the disorder into which they had been thrown by the untoward incident they were unable to follow up their victory. Canute retained possession of the field of battle, but stole away during the night and resumed the siege of London. Afterwards the Danes were defeated at Brentford on the Thames, and at Otford in Kent, and fled to the Isle of Sheppey; but being recruited, they met Edmund at Assandun (Ashdown, in Essex), where a battle was fought which virtually decided the fate of the West Saxon kings. Through a second act of treachery on the part of Edric, who fled at the decisive moment of the battle, with the portion of the army that he commanded, the Saxons were signally defeated, and their chief nobles left dead on the field. Edmund, undaunted by his great losses, wished still to continue the struggle, but Edric and the Witan persuaded him to be reconciled to Canute, and to consent to a division of the kingdom. Edmund retained London and all England south of the Thames, together with East Anglia and Essex, Canute taking possession of the other and larger portion. Edmund died on the 30th November of the same year, some affirm by the hand of Edric. He was buried in the great minster of Glastonbury, and on his death Canute became sole king of England.

EDOM. See IDUMEA.

EDRISI, IDRISI, or ALDRISI, the most eminent of the Arabian geographers, flourished in the 12th century. The

various parts of his life afford subjects of controversy rather than of precise information. The place and even the country in which he was born is the first subject of dispute. A Nubian and an Egyptian origin have both been assigned to him on the basis of a doubtful reading in his work, which speaks of "the Nile of Egypt which cuts our land." In 1663 Bochart stated that he had found in a manuscript of Leo Africanus that Edrisi was born at Mazara, in Sicily, in 1098. Next year, however, the manuscript was edited by Hottinger, in an appendix to his *Bibliothecarius Quadripartitus*, and it then appeared that the person supposed to be Edrisi was there named Esseriff Essachalli. Esseriff, or Scheriff, is indeed a usual appellation of Edrisi, but as it is only an honorary title and not a proper name, it does not help the identification. The most positive assertion on the subject is that of Casiri, who says (*Bibliotheca Arabico-Hispanica*, ii. 9), that if Edrisi, as appeared probable, were the person designated by the Mahometan writers as Abu-Abdallah Mohamad Ben Mohamad Ben Abdallah Ben Edris, he was born at Septa, or Ceuta, on the coast of Morocco, in 493 A.H. (1099 A.D.) Casiri not only qualifies his statement, but he does not mention the authorities from which it is derived; so that its acceptance rests only upon the confidence reposed in his learning and accuracy. Edrisi was long a mighty name in Northern Africa, but in 919 the dynasty was subverted by Mahedi Abdallah, and the proscribed wrecks of the family, according to D'Herbelot, afterwards sought refuge in Sicily. If we may trust the information of Casiri, Edrisi pursued his studies at Cordova, and from the accurate description he has given of Spain, it is probable that he had travelled through a great part of that country. Various circumstances prove that he removed to Sicily, and began to compose his great work under the patronage, and indeed at the express desire, of Roger II., king of that island. It was completed about 548 A.H. (1153 A.D.)

His work has appeared under various titles. The first and fullest seems to have been, *The going out of a Curious Man to explore the Regions of the Globe, its Provinces, Islands, Cities, and their Dimensions and Situation*. This is sometimes abbreviated. Sionita published it under the name of *Relaxation of the Curious Mind*; but the alternative title of *Nubian Geography*, which he and his companion imposed, is altogether arbitrary. It contains a full description of the whole world, as far as it was known to the author, who is said to have received reports from a number of learned explorers despatched expressly to collect information for his use. The world is divided into seven climates, commencing at the equinoctial line, and extending northwards to the limit at which the earth was supposed to be rendered uninhabitable by cold. Each climate is then divided by perpendicular lines into eleven equal parts, beginning with the western coast of Africa and ending with the eastern coast of Asia. The whole world is thus formed into 77 equal square compartments. The geographer begins with the first part of the first climate, including the western part of Central Africa, and proceeds eastward through the different divisions of this climate till he finds its termination in the Sea of China. He then returns to the first part of the second climate, and so proceeds till he reaches the eleventh part of the seventh climate, which terminates in the north-eastern extremity of Asia. The inconveniences of the arrangement are obvious; but the author appears to have been writing an illustrative treatise to accompany an actual representation of the world which he had engraved on a silver disk or possibly a silver globe.

Two valuable manuscripts of Edrisi exist in the Bibliothèque Nationale at Paris, and other two in the Bodleian Library. The first of the English MSS., which was brought over from Egypt

by Greaves, is written in the Arabic character peculiar to Northern Africa. It is illustrated by a map of the known world, and by 33 other maps, containing each part of a climate, so that there are maps only for the first three climates. The second manuscript, brought by Pococke from Syria, is written in the Arabic character used in that country, and bears the date of 906 A.H., or 1500 A.D. It consists of 320 leaves, and is illustrated by one general and 77 particular maps, the latter consequently including all the parts of every climate. The general map was published by Dr Vincent in his *Periplus of the Erythraean Sea*. A copy of Edrisi's work in the Escorial was destroyed by the great fire of 1671.

The geography of Edrisi, in the original Arabic, was printed at Rome in 1592, at the Medicean press, from a manuscript preserved in the grand-ducal library at Florence. Both the paper and printing are exceedingly neat, but the volume swarms with typographical errors and forms only a clumsy epitome of the original work. The description of Mecca, which is unaccountably omitted, has been supplied by Pococke from his manuscript. In most bibliographical works this impression has been characterized as one of the rarest of books; but Adler, in a visit to Florence, found in the palace there 1129 copies, which were exposed to sale at a moderate rate. In 1619, two Oriental scholars, Gabriel Sionita and Joannes Hezronita, published at Paris a Latin translation of Edrisi's work, bearing the title of *Geographia Nubiensis*; but it is far from accurate, particularly in the proper names. George Hieronymus Velschius, a German scholar, had prepared a copy of the Arabic original, with a Latin translation, which he purposed to have illustrated with notes; but death prevented the execution of his design, and his manuscript remains deposited in the university library of Jena. Casiri (*Lib. Ar. Hisp.*, ii. 13) mentions that he had determined to re-edit this work, but he appears never to have executed his intention. The part relating to Africa, pre-eminent certainly in point of importance, was very ably edited in 1796 by Hartmann, who collected together all the notices relating to each particular country, and annexed the statements of the countrymen and contemporaries of Edrisi, so that his work forms nearly a complete body of Arabian geography, as far as relates to Africa. He afterwards published *Hispania*, 3 vols., Marburg, 1801-1818.

A translation into French of the entire work, based on one of the MSS. of the Bibliothèque Nationale, was published by M. Jaubert in 1840, and forms volumes v. and vi. of the *Récueil de Voyages* issued by the Société de Géographie; but a good edition of the original text is still a desideratum. A number of Oriental scholars at Leyden determined in 1861 to undertake the task: Spain and Western Europe were assigned to Professor Dozy; Eastern Europe and Western Asia to Doctor Engelmann; Central and Eastern Asia to Deffrémery; and Africa to Professor Goetze. The first portion of the work appeared in 1866, under the title of *Description de l'Afrique et de l'Espagne par Edrisi, texte arabe publié par R. Dozy et M. J. de Goetze*; but the other collaborators have hitherto found it impossible to furnish their quota.

EDUCATION. This article is mainly concerned with the history of educational theories in the chief crises of their development. It has not been the object of the writer to give a history of the practical working of these theories, and still less to sketch the outlines of the science of teaching, which may be more conveniently dealt with under another head. The earliest education is that of the family. The child must be trained not to interfere with its parents' convenience, and to acquire those little arts which will help in maintaining the economy of the household. It was long before any attempt was made to improve generations as they succeeded each other. The earliest schools were those of the priests. As soon as an educated priesthood had taken the place of the diviners and jugglers who abused the credulity of the earliest races, schools of the prophets became a necessity. The training required for ceremonials, the common life apart from the family, the accomplishments of reading and singing, afforded a nucleus for the organization of culture and an opportunity for the efforts of a philosopher in advance of his age. Convenience and gratitude confirmed the monopoly of the clergy. The schools of Judea and Egypt were ecclesiastical. The Jews had but little effect on the progress of science, but our obligations to the priests of the Nile valley are great indeed. Much of their learning is obscure to us, but we have reason to conclude that there is no branch of science in which they did not progress at least so far as observation and careful registration of facts could carry them. They

were a source of enlightenment to surrounding nations. Not only the great lawgiver of the Jews, but those who were most active in stimulating the nascent energies of Hellas were careful to train themselves in the wisdom of the Egyptians. Greece, in giving an undying name to the literature of Alexandria, was only repaying the debt which she had incurred centuries before. Education became secular in countries where the priesthood did not exist as a separate body. At Rome, until Greece took her conqueror captive, a child was trained for the duties of life in the forum and the senate house. The Greeks were the first to develop a science of education distinct from ecclesiastical training. They divided their subjects of study into music and gymnastics, the one comprising all mental, the other all physical training. Music was at first little more than the study of the art of expression. But the range of intellectual education which had been developed by distinguished musical teachers was further widened by the Sophists, until it received a new stimulus and direction from the work of Socrates. Who can forget the picture left us by Plato of the Athenian palestra, in which Socrates was sure to find his most ready listeners and his most ardent disciples? In the intervals of running, wrestling, or the bath, the young Phædrus or Theætetus discoursed with the philosophers who had come to watch them on the good, the beautiful, and the true. The lowest efforts of their teachers were to fit them to maintain any view they might adopt with acuteness, elegance, readiness, and good taste. Their highest efforts were to stimulate a craving for the knowledge of the unknowable, to rouse a dissatisfaction with received opinions, and to excite a curiosity which grew stronger with the revelation of each successive mystery. Plato is the author of the first systematic treatise on education. He deals with the subject in his earlier dialogues, he enters into it with great fulness of detail in the *Republic*, and it occupies an important position in the *Laws*. The views thus expressed differ considerably in particulars, and it is therefore difficult to give concisely the precepts drawn up by him for our obedience. But the same spirit underlies his whole teaching. He never forgets that the beautiful is undistinguishable from the true, and that the mind is best fitted to solve difficult problems which has been trained by the enthusiastic contemplation of art. Plato proposes to intrust education to the state. He lays great stress on the influence of race and blood. Strong and worthy children are likely to spring from strong and worthy parents. Music and gymnastics are to develop the emotions of young men during their earliest years,—the one to strengthen their character for the contest of life, the other to excite in them varying feelings of resentment or tenderness. Reverence, the ornament of youth, is to be called forth by well-chosen fictions; a long and rigid training in science is to precede discussion on more important subjects. At length the goal is reached, and the ripest wisdom is ready to be applied to the most important practice.

The great work of Quintilian, although mainly a treatise on oratory, also contains incidentally a complete sketch of a theoretical education. His object is to show us how to form the man of practice. But what a high conception of practice is his. He wrote for a race of rulers. He multiplies much which has been attributed to the wisdom of a later age. He urges the importance of studying individual dispositions, and of tenderness in discipline and punishment. The Romans understood no systematic training except in oratory. In their eyes every citizen was a born commander, and they knew of no science of government and political economy. Cicero speaks slightly even of jurisprudence. Any one, he says, can make himself a jurisconsult in a week, but an orator is the production of a lifetime. No statement can be less true than that a perfect orator is a

perfect man. But wisdom and philanthropy broke even through that barrier, and the training which Quintilian expounds to us as intended only for the public speaker would, in the language of Milton, fit a man to perform justly, wisely, and magnanimously all the offices, both public and private, of peace and war.

Such are the ideas which the old world has left us. On one side man beautiful, active, clever, receptive, emotional, quick to feel, to show his feeling, to argue, to refine; greedy of the pleasures of the world, perhaps a little neglectful of its duties, fearing restraint as an unjust stinting of the bounty of nature, inquiring eagerly into every secret, strongly attached to the things of this life, but elevated by an unabated striving after the highest ideal; setting no value but upon faultless abstractions, and seeing reality only in heaven, on earth mere shadows, phantoms, and copies of the unseen. On the other side man practical, energetic, eloquent, tinged but not imbued with philosophy, trained to spare neither himself nor others, reading and thinking only with an apology; best engaged in defending a political principle, in maintaining with gravity and solemnity the conservation of ancient freedom, in leading armies through unexplored deserts, establishing roads, fortresses, settlements, the results of conquest, or in ordering and superintending the slow, certain, and utter annihilation of some enemy of Rome. Has the modern world ever surpassed their type? Can we in the present day produce anything by education except by combining, blending, and modifying the self-culture of the Greek or the self-sacrifice of the Roman?

The literary education of the earliest generation of Christians was obtained in the pagan schools, in those great imperial academies which existed even down to the 5th century, which flourished in Europe, Asia, and Africa, and attained perhaps their highest development and efficiency in Gaul. The first attempt to provide a special education for Christians was made at Alexandria, and is illustrated by the names of Clement and Origen. The later Latin fathers took a bolder stand, and rejected the suspicious aid of heathenism. Tertullian, Cyprian, and Jerome wished the antagonism between Christianity and Paganism to be recognized from the earliest years, and even Augustine condemned with harshness the culture to which he owed so much of his influence. The education of the Middle Ages was either that of the cloister or the castle. They stood in sharp contrast to each other. The object of the one was to form the young monk, of the other the young knight. We should indeed be ungrateful if we forgot the services of those illustrious monasteries, Monto Cassino, Fulda, or Tours, which kept alive the torch of learning throughout the dark ages, but it would be equally mistaken to attach an exaggerated importance to the teaching which they provided. Long hours were spent in the duties of the church, and in learning to take a part in elaborate and useless ceremonies. A most important part of the monastery was the writing room, where missals, psalters, and breviaries were copied and illuminated, and too often a masterpiece of classic literature was offered to make room for a treatise of one of the fathers or the sermon of an abbot. The discipline was hard; the rod ruled all with indiscriminating and impartial severity. How many generations have had to suffer for the floggings of those times! Hatred of learning, antagonism between the teacher and the taught, the belief that no training can be effectual which is not repulsive and distasteful, that no subject is proper for instruction which is acquired with ease and pleasure,—all these idols of false education have their root and origin in monkish cruelty. The joy of human life would have been in danger of being stamped out if it had not been for the warmth and colour of a young knight's boyhood. He was equally well

Middle Ages.

broken in to obedience and hardship, but the obedience was the willing service of a mistress whom he loved, and the hardship the permission to share the dangers of a leader whom he emulated. The seven arts of monkish training were Grammar, Dialectics, Rhetoric, Music, Arithmetic, Geometry, Astronomy, which together formed the *trivium* and *quadrivium*, the seven years' course, the divisions of which have profoundly affected our modern training. One of the earliest treatises based on this method was that of Martianus Capella, who in 470 published his *Satyra*, in nine books. The first two were devoted to the marriage between Philology and Mercury, the last seven were each devoted to the consideration of one of these liberal arts. Cassiodorus, who wrote *De Septem Disciplinis* about 500, was also largely used as a text book in the schools. Astronomy was taught by the *Cisio-Janus*, a collection of doggerel hexameters like the *Propria quæ muribus*, which contained the chief festivals in each month, with a *memoria technica* for recollecting when they occurred. The seven knightly accomplishments, as historians tell us, were to ride, to swim, to shoot with the bow, to box, to hawk, to play chess, and to make verses. The verses thus made were not in Latin, bald imitations of Ovid or Horace, whose pagan beauties were wrested into the service of religion, but sonnets, ballads, and canzonets in soft Provençal or melodious Italian. In nothing, perhaps, is the difference between these two forms of education more clearly shown than in their relations to women. A young monk was brought up to regard a woman as the worst among the many temptations of St Antony. His life knew no domestic tenderness or affection. He was surrounded and cared for by celibates, to be himself a celibate. A page was trained to receive his best reward and worst punishment from the smile or frown of the lady of the castle, and as he grew to manhood to cherish an absorbing passion as the strongest stimulus to a noble life, and the contemplation of female virtue, as embodied in an Isolde or a Beatrice, as the truest earnest of future immortality.

Both these forms of education disappeared before the Renaissance and the Reformation. But we must not suppose that no efforts were made to improve upon the narrowness of the schoolmen or the idleness of chivalry. The schools of Charles the Great have lately been investigated by Mr Mullinger, but we do not find that they materially advanced the science of education. Vincent of Beauvais has left us a very complete treatise on education, written about the year 1245. He was the friend and counsellor of St Louis, and we may discern his influence in the instructions which were left by that sainted king for the guidance of his son and daughter through life. The end of this period was marked by the rise of universities. Bologna devoted itself to law, and numbered 12,000 students at the end of the 12th century. Salerno adopted as its special province the study of medicine, and Paris was thronged with students from all parts of Europe, who were anxious to devote themselves to a theology which passed by indefinite gradations into philosophy. The 14th and 15th centuries witnessed the rise of universities and academies in almost every portion of Europe. Perhaps the most interesting among these precursors of a higher culture were the Brethren of the Common Life, who were domiciled in the rich meadows of the Yssel, in the Northern Netherlands. The metropolis of their organization was Deventer, the best known name among them that of Gerhard Groote. They devoted themselves with all humility and self-sacrifice to the education of children. Their schools were crowded. Bois-le-duc numbered 1200 pupils, Zwolle 1500. For a hundred years no part of Europe shone with a brighter lustre. As the divine comedy of Dante represents for us the learning and piety of the Middle Ages in Italy, so the

Imitation of Thomas à Kempis keeps alive for us the memory of the purity and sweetness of the Dutch community. But they had not sufficient strength to preserve their supremacy among the necessary developments of the age. They could not support the glare of the new Italian learning, they obtained, and it may be feared deserved, the title of obscurantists. The *Epistolæ Obscurorum Virorum*, the wittiest squib of the Middle Ages, which was so true and so subtle in its satire that it was hailed as a blow struck in defence of the ancient learning, consists in great part of the lamentations of the brethren of Deventer over the new age, which they could not either comprehend or withstand. The education of the Renaissance is best represented by the name of Erasmus, that of the Reformation by the names of Luther and Melancthon. We have no space to give an account of that marvellous resurrection of the mind and spirit of Europe when touched by the dead hand of an extinct civilization. The history of the revival of letters belongs rather to the general history of literature than to that of education. But there are two names whom we ought not to pass over. Vittorino da Feltre was summoned by the Gonzagas to Mantua in 1424; he was lodged in a spacious palace, with galleries, halls, and colonnades decorated with frescoes of playing children. In person he was small, quick, and lively—a born schoolmaster, whose whole time was spent in devotion to his pupils. We are told of the children of his patron, how Prince Gonzaga recited 200 verses of his own composition at the age of fourteen, and how Princess Cecilia wrote elegant Greek at the age of ten. Vittorino died in 1477. He seems to have reached the highest point of excellence as a practical schoolmaster of the Italian Renaissance. Castiglione, on the other hand, has left us in his *Cortigiano* the sketch of a cultivated nobleman in those most cultivated days. He shows by what precepts and practice the golden youths of Verona and Venice were formed, who live for us in the plays of Shakespeare as models of knightly excellence. For our instruction, it is better to have recourse to the pages of Erasmus. He has written the most minute account of his method of teaching. The child is to be formed into a good Greek and Latin scholar and a pious man. He fully grasps the truth that improvement must be natural and gradual. Letters are to be taught playing. The rules of grammar are to be few and short. Every means of arousing interest in the work is to be fully employed. Erasmus is no Ciceronian. Latin is to be taught so as to be of use—a living language adapted to modern wants. Children should learn an art—painting, sculpture, or architecture. Idleness is above all things to be avoided. The education of girls is as necessary and important as that of boys. Much depends upon home influence; obedience must be strict, but not too severe. We must take account of individual peculiarities, and not force children into cloisters against their will. We shall obtain the best result by following nature. It is easy to see what a contrast this scheme presented to the monkish training,—to the routine of useless technicalities enforced amidst the shouts of teachers and the lamentations of the taught.

Still this culture was but for the few. Luther brought the schoolmaster into the cottage, and laid the foundations of the system which is the chief honour and strength of modern Germany, a system by which the child of the humblest peasant, by slow but certain gradations, receives the best education which the country can afford. The precepts of Luther found their way into the hearts of his countrymen in short, pithy sentences, like the sayings of poor Richard. The purification and widening of education went hand in hand with the purification of religion, and these claims to affection are indissolubly united in the minds of his countrymen. Melancthon, from his editions

of school books and his practical labours in education, earned the title of *Præceptor Germaniæ*. Aristotle had been dethroned from his pre-eminence in the schools, and Melancthon attempted to supply his place. He appreciated the importance of Greek, the terror of the obscurantists, and is the author of a Greek grammar. He wrote elementary books on each department of the *trivium*—grammar, dialectic, and rhetoric. He made some way with the studies of the *quadrivium*, and wrote *Initia doctrinæ Physicæ*, a primer of physical science. He lectured at the university of Wittenberg, and for ten years, from 1519 to 1529, kept a *schola privata* in his own house. Horace was his favourite classic. His pupils were taught to learn the whole of it by heart, ten lines at a time. The tender refined lines of his well-known portraits show clearly the character of the painful, accurate scholar, and contrast with the burly powerful form of the genial Luther. He died in 1560, racked with anxiety for the church which he had helped to found. If he did not carry Protestantism into the heart of the peasant, he at least made it acceptable to the intellect of the man of letters.

We now come to the names of three theoretical and practical teachers who have exercised and are still exercising a profound effect over education. The so-called Latin school, the parent of the gymnasium and the lycée, had spread all over Europe, and was especially flourishing in Germany. The programmes and time tables in use in these establishments have come down to us, and we possess notices of the lives and labours of many of the earliest teachers. It is not difficult to trace a picture of the education which the Reformation offered to the middle classes of Europe. Ample materials exist in German histories of education. We must confine ourselves to those moments which were of vital influence in the development of the science. One school stands pre-eminently before the rest, situated in that border city on the debatable land between France and Germany, which has known how to combine and reconcile the peculiarities of French and German culture. Strasburg, besides a school of theology which unites the depth of Germany to the clearness and vivacity of France, educated the gilded youth of the 16th century under Sturm, as it trained the statesmen and diplomatists of the 18th under Koeh. John Sturm of Strasburg was the friend of Ascham, the author of the *Scholemaster*, and the tutor of Queen Elizabeth. It was Ascham who found Lady Jane Grey alone in her room at Bradgate bending her neck over the page of Plato when all the rest of her family were following the chase. Sturm was the first great head master, the progenitor of Busbys if not of Arnolds. He lived and worked till the age of eighty-two. He was a friend of all the most distinguished men of his age, the chosen representative of the Protestant cause in Europe, the ambassador to foreign powers. He was believed to be better informed than any man of his time of the complications of foreign politics. Rarely did an envoy pass from France to Germany without turning aside to profit by his experience. But the chief energies of his life were devoted to teaching. He drew his scholars from the whole of Europe; Portugal, Poland, England sent their contingent to his halls. In 1578 his school numbered several thousand students; he supplied at once the place of the cloister and the castle. What he most insisted upon was the teaching of Latin, not the conversational *lingua franca* of Erasmus, but pure, elegant Ciceronian Latinity. He may be called the introducer of scholarship into the schools, a scholarship which as yet took little account of Greek. His pupils would write elegant letters, deliver elegant Latin speeches, be familiar, if not with the thoughts, at least with the language of the ancients, would be scholars in order that they might be gentlemen. Our space will not permit us to

trace the whole course of his influence, but he is in all probability as much answerable as any one for the euphuistic refinement which overspread Europe in the 16th century, and which went far to ruin and corrupt its literatures. Nowhere perhaps had he more effect than in England. Our older public schools, on breaking with the ancient faith, looked to Sturm as their model of Protestant education. His name and example became familiar to us by the exertions of his friend Ascham. Westminster, under the long reign of Busby, received a form which was generally accepted as the type of a gentleman's education. The Public School Commission of 1862 found that the lines laid down by the great citizen of Strasburg, and copied by his admirers, had remained unchanged until within the memory of the present generation. Wolfgang Ratke or Ratichius was born in Holstein in 1571. He anticipated some of the best improvements in the method of teaching which have been made in modern times. He was like many of those who have tried to improve existing methods in advance of his age, and he was rewarded for his labours at Augsburg, Weimar, and Kothen by persecution and imprisonment. Can we wonder that education has improved so slowly when so much pains has been taken to silence and extinguish those who have devoted themselves to its improvement? His chief rules were as follows. 1. Begin everything with prayer. 2. Do everything in order, following the course of nature. 3. One thing at a time. 4. Often repeat the same thing. 5. Teach everything first in the mother tongue. 6. Proceed from the mother tongue to other languages. 7. Teach without compulsion. Do not beat children to make them learn. Pupils must love their masters, not hate them. Nothing should be learnt by heart. Sufficient time should be given to play and recreation. Learn one thing before going on to another. Do not teach for two hours consecutively. 8. Uniformity in teaching, also in school books, especially grammars, which may with advantage be made comparative. 9. Teach a thing first, and then the reason of it. Give no rules before you have given the examples. Teach no language out of the grammar, but out of authors. 10. Let everything be taught by induction and experiment. Most of these precepts are accepted by all good teachers in the present day; all of them are full of wisdom. Unfortunately their author saw the faults of the teaching of his time more clearly than the means to remove them, and he was more successful in forming precepts than in carrying them out. Notwithstanding these drawbacks, he deserves an honourable place among the forerunners of a rational education.

John Amos Comenius was the antithesis to Sturm, and a greater man than Ratke. Born a Moravian, he passed a wandering life, among the troubles of the Thirty Years' War, in poverty and obscurity. But his ideas were accepted by the most advanced thinkers of the age, notably in many respects by our own Milton, and by Oxenstiern the chancellor of Sweden. His school books were spread throughout Europe. The *Janua Linguarum Reserata* was translated into twelve European and several Asiatic languages. His works, especially the *Didascalica magna*, an encyclopedia of the science of education, are constantly reprinted at the present day; and the system which he sketched will be found to foreshadow the education of the future. He was repelled and disgusted by the long delays and pedantries of the schools. His ardent mind conceived that if teachers would but follow nature instead of forcing it against its bent, take full advantage of the innate desire for activity and growth, all men might be able to learn all things. Languages should be taught as the mother tongue is taught, by conversations on ordinary topics; pictures, object lessons, should be freely used; teaching should go hand in hand with a cheerful, elegant, and happy life. Comenius included in his course

the teaching of the mother tongue, singing, economy, and politics, the history of the world, physical geography, and a knowledge of arts and handicrafts. But the principle on which he most insisted, which forms the special point of his teaching, and in which he is followed by Milton, is that the teaching of words and things must go together hand in hand. When we consider how much time is spent over new languages, what waste of energy is lavished on mere preparation, how it takes so long to lay a foundation that there is no time to rear a building upon it, we must conclude that it is in the acceptance and development of this principle that the improvement of education will in the future consist. Any one who attempts to inculcate this great reform will find that its first principles are contained in the writings of Comenius. But this is not the whole of his claim upon our gratitude. He was one of the first advocates of the teaching of science in schools. His kindness, gentleness, and sympathy make him the forerunner of Pestalozzi. His general principles of education would not sound strange in the treatise of Herbert Spencer.

The Protestant schools were now the best in Europe, and the monkish institutions were left to decay. Catholics would have remained behind in the race if it had not been for the Jesuits. Ignatius Loyola gave this direction to the order which he founded, and the programme of studies, which dates from the end of the 16th century, is in use, with certain modifications, in English Jesuit schools at the present day. In 1550 the first Jesuit school was opened in Germany; in 1700 the order possessed 612 colleges, 157 normal schools, 59 noviciates, 340 residences, 200 missions, 29 professed homes, and 24 universities. The college of Clermont had 3000 students in 1695. Every Jesuit college was divided into two parts, the one for higher the other for lower education,—the *studia superiora*, and the *studia inferiora*. The *studia inferiora*, answering to the modern gymnasium, was divided into five classes. The first three were classes of grammar (rudiments), grammar (accidence), and syntax, the last two humanity and rhetoric. The motto of the schools was *lege, scribe, loquere*,—you must learn not only to read and write a dead language, but to talk. Purism was even more exaggerated than by Sturm. No word might be used which did not rest upon a special authority. The composition of Latin verses was strongly encouraged, and the performance of Latin plays. Greek was studied to some extent; mathematics, geography, music, and the mother tongues were neglected. The *studia superiora* began with a philosophical course of two or three years. In the first year logic was taught, in the second the books of Aristotle *de celo*, the first book *de generatione*, and the *Metæorologica*. In the third year the second book *de generatione*, the books *de anima*, and the *Metaphysics*. After the completion of the philosophical course the pupil studied theology for four years. The Jesuits used to the full the great engine of emulation. Their classes were divided into two parts, Romans and Carthaginians; swords, shields, and lances hung on the walls, and were carried off in triumph as either party claimed the victory by a fortunate answer. It would be unfair to deny the merits of the education of the Jesuits. Bacon speaks of them in more than one passage as the revivers of this most important art. *Quum talis sis utinam noster esset*. Descartes approved of their system; Chateaubriand regarded their suppression as a calamity to civilization and enlightenment. They were probably the first to bring the teacher into close connection with the taught. According to their ideal the teacher was neither inclosed in a cloister, secluded from his pupils, nor did he keep order by stamping, raving, and flogging. He was encouraged to apply his mind and soul to the mind and soul of his pupil; to study the nature, the disposition,

the parents of his scholars; to follow nature as far as possible, or rather to lie in wait for it and discover its weak points, and where it could be most easily attacked. Doubtless the Jesuits have shown a love, devotion, and self-sacrifice in education, which is worthy of the highest praise; no teacher who would compete with them can dare do less. On the other hand, they are open to grave accusation. Their watchful care degenerated into surveillance, which lay-schools have borrowed from them; their study of nature has led them to confession and direction. They have tracked out the soul to its recesses, that they might slay it there, and generate another in its place; they educated each mind according to its powers, that it might be a more subservient tool to their own purposes. They taught the accomplishments which the world loves, but their chief object was to amuse the mind and stifle inquiry; they encouraged Latin verses, because they were a convenient plaything on which powers might be exercised which could have been better employed in understanding and discussing higher subjects; they were the patrons of school plays, of public prizes, declamations, examinations, and other exhibitions, in which the parents were more considered than the boys; they regarded the claims of education, not as a desire to be encouraged, but as a demand to be played with and propitiated; they gave the best education of their time in order to acquire confidence, but they became the chief obstacle to the improvement of education; they did not care for enlightenment, but only for the influence which they could derive from a supposed regard for enlightenment. Whatever may have been the service of Jesuits in past times, we have little to hope for them in the improvement of education at present. Governments have, on the whole, acted wisely by checking and suppressing their colleges. The *ratio studiorum* is antiquated and difficult to reform. In 1831 it was brought more into accordance with modern ideas by Roothaan, the general of the order. Beckx his successor has, if anything, pursued a policy of retrogression. The Italian Government, in taking possession of Rome, found that the pupils of the Collegio Romano were far below the level of modern requirements.

It may be imagined that, by this organization both Catholics and Protestants were apt to degenerate into pedantry, both in name and purpose. The schoolmaster had a great deal too much the best of it. The Latin school was tabulated and organized until every half hour of a boy's time was occupied; the Jesuit school took possession of the pupil body and soul. It was, therefore, to be expected that a stand should be made for common sense in the direction of practice rather than theory, of wisdom instead of learning. Montaigne has left us the most delightful utterances about education. He says that the faults of the education of his day consist in over-estimating the intellect and rejecting morality, in exaggerating memory and depreciating useful knowledge. He recommends a tutor who should draw out the pupil's own power and originality, to teach how to live well and to die well, to enforce a lesson by practice, to put the mother tongue before foreign tongues, to teach all manly exercises, to educate the perfect man. Away with force and compulsion, with severity and the rod. John Locke, more than a hundred years afterwards, made a more powerful and systematic attack upon useless knowledge. His theory of the origin of ideas led him to assign great importance to education, while his knowledge of the operations of the human mind lends a special value to his advice. His treatise has received in England more attention than it deserves, partly because we have so few books written upon the subject on which he treats. Part of his advice is useless at the present day; part it would be well to follow, or at any rate to consider seriously, especially his condemna-

tion of repetition by heart as a means of strengthening the memory, and of Latin verses and themes. He sets before himself the production of the man, a sound mind in a sound body. His knowledge of medicine gives great value to his advice on the earliest education, although he probably exaggerates the benefits of enforced hardships. He recommends home education without harshness or severity of discipline. Emulation is to be the chief spring of action; knowledge is far less valuable than a well-trained mind. He prizes that knowledge most which fits a man for the duties of the world, speaking languages, accounts, history, law, logic, rhetoric, natural philosophy. He inculcates the importance of drawing, dancing, riding, fencing, and trades. The part of his advice which made most impression upon his contemporaries was the teaching of reading and arithmetic by well-considered games, the discouragement of an undue compulsion and punishment, and the teaching of language without the drudgery of grammar. In those respects he has undoubtedly anticipated modern discoveries. He is a strong advocate for home education under a private tutor, and his bitterness against public schools is as vehement as that of Cowper.

Far more important in the literature of this subject than the treatise of Locke is the *Treatise of Education* by Milton, "the few observations," as he tells us, "which flowered off, and are, as it were, the burnishings of many studious and contemplative years spent in the search for civil and religious knowledge." This essay is addressed to Samuel Hartlib, a great friend of Comenius, and probably refers to a project of establishing a university in London. "I will point you out," Milton says, "the right path of a virtuous and noble education,—laborious, indeed, at first ascent, but else so smooth and green and full of goodly prospects and melodious sounds on every side, that the harp of Orpheus is not more charming. This is to be done between twelve and one-and-twenty, in an academy containing about a hundred and thirty scholars, which shall be at once school and university,—not needing a remove to any other house of scholarship except it be some peculiar college of law and physics, where they mean to be practitioners." The important truth enunciated is quite in the spirit of Comenius that the learning of things and words is to go hand in hand. The curriculum is very large. Latin, Greek, arithmetic, geometry, agriculture, geography, physiology, physics, trigonometry, fortification, architecture, engineering, navigation, anatomy, medicine, poetry, Italian, law both Roman and English, Hebrew with Chaldee and Syriac, history, oratory, poetics. But the scholars are not to be book-worms. They are to be trained for war, both on foot and on horseback, to be practised "in all the locks and gripes of wrestling," they are to "recreate and compose their travailed spirits with the divine harmonies of music heard or learnt." "In those vernal seasons of the year when the air is calm and pleasant, it were an injury and a sullonness against nature not to go out and see her riches, and partake in her rejoicing with heaven and earth. I should not then be a persuader to them of studying much then, after two or three years that they have well laid their grounds, but to ride out in companies with prudent and staid guides to all the quarters of the land." The whole treatise is full of wisdom, and deserves to be studied again and again. Visionary as it may appear to some at first sight, if translated into the language of our own day, it will be found to abound with sound practical advice. "Only," Milton says in conclusion, "I believe that this is not a bow for every man to shoot who counts himself a teacher, but will require sinews almost equal to those which Homer gave Ulysses; yet I am persuaded that it may prove much more easy in the essay than it now seems at a distance, and much more illustrious if God have so decided and this

age have spirit and capacity enough to apprehend." Almost while Milton was writing this treatise, he might have seen an attempt to realize something of his ideal in Port Royal. What a charm does this name awaken! Yet how few of us have made a pilgrimage to that secluded valley! Here we find, for the first time in the modern world, the highest gifts of the greatest men of a country applied to the business of education. Arnauld, Lancelot, Nicole did not commence by being educational philosophers. They began with a small school, and developed their method as they proceeded. Their success has seldom been surpassed. But a more lasting memorial than their pupils are the books which they sent out, which bear the name of their cloister. The *Port Royal Logic*, *General Grammar*, *Greek*, *Latin*, *Italian*, and *Spanish Grammars*, the *Garden of Greek Roots* which taught Greek to Gibbon, the *Port Royal Geometry*, and their translations of the classics held the first place among school books for more than a century. The success of the Jansenists was too much for the jealousy of the Jesuits. Neither piety, nor wit, nor virtue could save them. A light was quenched which would have given an entirely different direction to the education of France and of Europe. No one can visit without emotion that retired nook which lies hidden among the forests of Versailles, where the old brick dove-cot, the pillars of the church, the trees of the desert alone remain to speak to us of Pascal, Racine, and the Mère Angélique. The principles of Port Royal found some supporters in a later time, in the better days of French education before monarchism and militarism had crushed the life out of the nation. Rollin is never mentioned without the epithet *bon*, a testimony to his wisdom, virtue, and simplicity. Fénelon may be reckoned as belonging to the same school, but he was more fitted to mix and grapple with mankind.

No history of education would be complete without the name of August Hermann Francke, the founder of the school of Pietists, and of a number of institutions which now form almost a suburb in the town of Halle to which his labours were devoted. The first scenes of his activity were Leipzig and Dresden; but in 1692, at the age of 29, he was made pastor of Glaucha near Halle, and professor in the newly established university. Three years later he commenced his poor school with a capital of seven guilders which he found in the poor box of his house. At his death in 1727 he left behind him the following institutions:—a pædagogium, or training college, with 82 scholars and 70 teachers receiving education, and attendants; the Latin school of the orphan asylum, with 3 inspectors, 32 teachers, 400 scholars, and 10 servants; the German town schools, with 4 inspectors, 98 teachers, 8 female teachers, and 1725 boys and girls. The establishment for orphan children contained 100 boys, 34 girls, and 10 attendants. A cheap public dining table was attended by 255 students and 360 poor scholars, and besides this there was an apothecary's and a bookseller's shop. Francke's principles of education were strictly religious. Hebrew was included in his curriculum, but the heathen classics were treated with slight respect. The *Homilies* of Macarius were read in the place of Thucydides. As might be expected, the rules laid down for discipline and moral training breathed a spirit of deep affection and sympathy. Francke's great merit, however, is to have left us a model of institutions by which children of all ranks may receive an education to fit them for any position in life. The Franckesche Stiftungen are still, next to the university, the centre of the intellectual life of Halle, and the different schools which they contain give instruction to 3500 children.

We now come to the book which has had more influence than any other on the education of later times. The *Emile* of Rousseau was published in 1762. It produced an

astounding effect throughout Europe. Those were days when the whole cultivated world vibrated to any touch of new philosophy. French had superseded Latin as the general medium of thought. French learning stood in the same relation to the rest of Europe as German learning does now; and any discovery of D'Alembert, Rousseau, or Manpertuis travelled with inconceivable speed from Versailles to Schonbrunn, from the Spree to the Neva. Kant in his distant home of Königsberg broke for one day through his habits, more regular than the town clock, and stayed at home to study the new revelation. The burthen of Rousseau's message was nature, such a nature as never did and never will exist, but still a name for an ideal worthy of our struggles. He revolted against the false civilization which he saw around him; he was penetrated with sorrow at the shams of government and society, at the misery of the poor existing side by side with the heartlessness of the rich. The child should be the pupil of nature. He lays great stress on the earliest education. The first year of life is in every respect the most important. Nature must be closely followed. The child's tears are petitions which should be granted. The naughtiness of children comes from weakness; make the child strong and he will be good. Children's destructiveness is a form of activity. Do not be too anxious to make children talk, be satisfied with a small vocabulary. Lay aside all padded caps and baby jumpers. Let children learn to walk by learning that it hurts them to fall. Do not insist too much on the duty of obedience as on the necessity of submission to natural laws. Do not argue too much with children; educate the heart to wish for right actions, before all things study nature. The chief moral principle is *do no one harm*. Émile is to be taught by the real things of life, by observation and experience. At twelve years old he is scarcely to know what a book is; to be able to read and write at fifteen is quite enough. We must first make him a man, and that chiefly by athletic exercises. Educate his sight to measure, count, and weigh accurately; teach him to draw; tune his ear to time and harmony; give him simple food, but let him eat as much as he likes. Thus at twelve years old Émile is a real child of nature. His carriage and bearing are fair and confident, his nature open and candid, his speech simple and to the point; his ideas are few but clear; he knows nothing by learning, much by experience. He has read deeply in the book of nature. His mind is not on his tongue but in his head. He speaks only one language, but knows what he is saying, and can do what he cannot describe. Routine and custom are unknown to him; authority and example affect him not; he does what he thinks right. He understands nothing of duty and obedience, but he will do what you ask him, and will expect a similar service of you in return. His strength and body are fully developed; he is first-rate at running, jumping, and judging distances. Should he die at this age he will so far have lived his life. From twelve to fifteen Émile's practical education is to continue. He is still to avoid books which teach not learning itself but to appear learned. He is to be taught and to practice some handicraft. Half the value of education is to waste time wisely, to tide over dangerous years with safety, until the character is better able to stand temptation. At fifteen a new epoch commences. The passions are awakened; the care of the teacher should now redouble; he should never leave the helm. Émile having gradually acquired the love of himself and of those immediately about him, will begin to love his kind. Now is the time to teach him history, and the machinery of society, the world as it is and as it might be. Still an encumbrance of useless and burdensome knowledge is to be avoided. Between this age and manhood Émile learns all that it is necessary for him to know. It is, per-

haps, strange that a book in many respects so wild and fantastic should have produced so great a practical effect. In pursuance of its precepts, children went about naked, were not allowed to read, and when they grew up wore the simplest clothes, and cared for little learning except the study of nature and Plutarch. The catastrophe of the French Revolution has made the importance of Émile less apparent to us. Much of the heroism of that time is doubtless due to the exaltation produced by the sweeping away of abuses, and the approach of a brighter age. But we must not forget that the first generation of Émile was just thirty years old in 1792; that many of the Girondins, the Marseillais, the soldiers and generals of Carnot and Napoleon had been bred in that hardy school. There is no more interesting chapter in the history of education than the tracing back of epochs of special activity to the obscure source from which they arose. Thus the Whigs of the Reform Bill sprang from the wits of Edinburgh, the heroes of the Rebellion from the divines who translated the Bible, the martyrs of the Revolution from the philosophers of the Encyclopædia.

The teaching of Rousseau found its practical expression in the *philanthropin* of Dessau, a school founded by Basedow, the friend of Goethe and Lavater, one of the two prophets between whom the world-child sat bodkin in that memorable post-chaise journey of which Goethe has left us an account. The principles of the teaching given in this establishment were very much those of Comenius, the combination of words and things. An amusing account of the instruction given in this school, which at this time consisted of only thirteen pupils, has come down to us, a translation of which is given in the excellent work of Mr Quick on educational reformers. The little ones have gone through the oddest performances. They play at "word of command." Eight or ten stand in a line like soldiers, and Herr Wolke is officer. He gives the word in Latin, and they must do whatever he says. For instance when he says "claudite oculos," they all shut their eyes; when he says "circumspicite," they look about them; "imitamini autorem," they draw the waxed thread like cobblers. Herr Wolke gives a thousand different commands in the drollest fashion. Another game, "the hiding game," may also be described. Some one writes a name and hides it from the children, the name of some part of the body, or of a plant or animal, or metal, and the children guess what it is. Whoever guesses right gets an apple or a piece of cake, one of the visitors wrote "intestina," and told the children it was part of the body. Then the guessing began, one guessed caput, another nasus, another os, another manus, pes, digiti, pectus, and so forth for a long time, but one of them hits it at last. Next Herr Wolke wrote the name of a beast or quadruped, then came the guesses, leo, ursus, camelus, elephas, and so on, till one guessed right it was mus. Then a town was written, and they guessed Lisbon, Madrid, Paris, London, till a child won with St Petersburg. They had another game which was this. Herr Wolke gave the command in Latin, and they imitated the noises of different animals, and made the visitors laugh till they were tired. They roared like lions, crowed like cocks, mewled like cats, just as they were bid. Yet Kant found a great deal to praise in this school, and spoke of its influence as one of the best hopes of the future, and as "the only school where the teachers had liberty to act according to their own methods and schemes, and where they were in free communication both among themselves and with all learned men throughout Germany."

A more successful labourer in the same school was Salzmann, who bought the property of Schnepfenthal near Gotha in 1784, and established a school there, which still exists as a flourishing institution. He gave full scope to

the doctrines of the philanthropists; the limits of learning were enlarged; study became a pleasure instead of a pain, scope was given for healthy exercise; the school became light, airy, and cheerful. A charge of superficiality and weakness was brought against this method of instruction; but the gratitude which our generation of teachers owes to the unbounded love and faith of these devoted men cannot be denied or refused. The end of the 18th century saw a great development given to classical studies. The names of Cellarius, Gesner, Ernesti, and Heyne are perhaps more celebrated as scholars than as schoolmasters. To them we owe the great importance attached to the study of the classics, both on the Continent and in England. They brought into the schools the philology which F. A. Wolf had organized for the universities. Pestalozzi, on the other hand, was completely and entirely devoted to education. His greatest merit is that he set an example of absolute self-abnegation, that he lived with his pupils, played, starved, and suffered with them, and clung to their minds and hearts with an affectionate sympathy which revealed to him every minute difference of character and disposition. Pestalozzi was born at Zurich in 1746. His father died when he was young, and he was brought up by his mother. His earliest years were spent in schemes for improving the condition of the people. The death of his friend Bluntschli turned him from political schemes, and induced him to devote himself to education. He married at 23, and bought a piece of waste land in Aargau, where he attempted the cultivation of madder. Pestalozzi knew nothing of business, and the plan failed. Before this he had opened his farm-house as a school; but in 1780 he had to give this up also. His first book published at this time was *The Evening Hours of a Hermit*, a series of aphorisms and reflections. This was followed by his masterpiece, *Leonard and Gertrude*, an account of the gradual reformation, first of a household, and then of a whole village, by the efforts of a good and devoted woman. It was read with avidity in Germany, and the name of Pestalozzi was rescued from obscurity. His attempts to follow up this first literary success were failures. The French invasion of Switzerland in 1798 brought into relief his truly heroic character. A number of children were left in Canton Unterwalden on the shores of the Lake of Lucerne, without parents, home, food, or shelter. Pestalozzi collected a number of them into a deserted convent, and spent his energies in reclaiming them. "I was," he says, "from morning till evening, almost alone in their midst. Everything which was done for their body or soul proceeded from my hand. Every assistance, every help in time of need, every teaching which they received came immediately from me. My hand lay in their hand, my eye rested on their eye, my tears flowed with theirs, and my laughter accompanied theirs. They were out of the world, they were out of Stanz; they were with me, and I was with them. Their soup was mine, their drink was mine. I had nothing, I had no housekeeping, no friend, no servants around me; I had them alone. Were they well I stood in their midst; were they ill, I was at their side. I slept in the middle of them. I was the last who went to bed at night, the first who rose in the morning. Even in bed I prayed and taught with them until they were asleep,—they wished it to be so." Thus he passed the winter, but in June 1799 the building was required by the French for a hospital, and the children were dispersed. We have dwelt especially on this episode of Pestalozzi's life, because in this devotion lay his strength. In 1801 he gave an exposition of his ideas on education in the book *How Gertrude teaches her Children*. His method is to proceed from the easier to the more difficult. To begin with observation, to pass from observation to consciousness, from consciousness to speech. Then come measuring, drawing, writing, numbers, and so

reckoning. In 1799 he had been enabled to establish a school at Burgdorf, where he remained till 1804. In 1802, he went as deputy to Paris, and did his best to interest Napoleon in a scheme of national education; but the great conqueror said that he could not trouble himself about the alphabet. In 1805 he removed to Yverdon on the Lake of Neuchâtel, and for twenty years worked steadily at his task. He was visited by all who took interest in education,—Talleyrand, Capo d'Istria, and Madame de Staël. He was praised by Wilhelm von Humboldt and by Fichte. His pupils included Ramsauer, Delbrück, Blochmann, Carl Ritter, Frobel, and Zeller. About 1815 dissensions broke out among the teachers of the school, and Pestalozzi's last ten years were chequered by weariness and sorrow. In 1825 he retired to Neuhof, the home of his youth; and after writing the adventures of his life, and his last work, the *Swan's Song*, he died in 1827. As he said himself, the real work of his life did not lie in Burgdorf or in Yverdon, the products rather of his weakness than of his strength. It lay in the principles of education which he practised, the development of his observation, the training of the whole man, the sympathetic application of the teacher to the taught, of which he left an example in his six months' labours at Stanz. He showed what truth there was in the principles of Comenius and Rousseau, in the union of training with information, and the submissive following of nature; he has had the deepest effect on all branches of education since his time, and his influence is far from being exhausted.

The *Émile* of Rousseau was the point of departure for an awakened interest in educational theories which has continued unto the present day. Few thinkers of eminence during the last hundred years have failed to offer their contributions more or less directly on this subject. Poets like Richter, Herder, and Goethe, philosophers such as Kant, Fichte, Hegel, Schleiermacher, and Schopenhauer, psychologists such as Herbart and Benke, have left directions for our guidance. Indeed, during this time the science of education or pedagogy, as the Germans call it, may have been said to have come into existence. It has attracted but little attention in England; but it is an important subject of study at all German universities, and we may hope that the example given by the establishment of chairs of education in the Scotch universities may soon be followed by the other great centres of instruction in Great Britain. Jean Paul called his book *Levana*, after the Roman goddess to whom the father dedicated his new-born child, in token that he intended to rear it to manhood. He lays great stress on the preservation of individuality of character, a merit which he possessed himself in so high a degree. The second part of *Wilhelm Meister* is in the main a treatise upon education. The Goethe essays of Carlyle have made us familiar with the mysteries of the pedagogy province, the solemn gestures of the three reverences, the long cloisters which contain the history of God's dealings with the human race. The most characteristic passage is that which describes the father's return to the country of education after a year's absence. As he is riding alone, wondering in what guise he will meet his son, a multitude of horses rush by at full gallop. "The monstrous hurly-burly whirls past the wanderer; a fair boy among the keepers looks at him with surprise, pulls in, leaps down, and embraces his father." He then learns that an agricultural life had not suited his son, that the superiors had discovered that he was fond of animals, and had set him to that occupation for which nature had destined him.

The system of Jacotot has aroused great interest in this country. Its author was born at Dijon in 1770. In 1815 he retired to Louvain and became professor there, and director of the Belgian military school. He died in 1840. His method of teaching is based on three principles:—

1. All men have an equal intelligence;
2. Every man has received from God the faculty of being able to instruct himself;
3. Every thing is in every thing.

The first of these principles is certainly wrong, although Jacotot tried to explain it by asserting that, although men had the same intelligence, they differed widely in the will to make use of it. Still it is important to assert that nearly all men are capable of receiving some intellectual education, provided the studies to which they are directed are wide enough to engage their faculties, and the means taken to interest them are sufficiently ingenious. The second principle lays down that it is more necessary to stimulate the pupil to learn for himself than to teach him didactically. The third principle explains the process which Jacotot adopted. To one learning a language for the first time he would give a short passage of a few lines, and encourage the pupil to study first the words, then the letters, then the grammar, then the full meaning of the expressions, until by iteration and coercion a single paragraph took the place of an entire literature. Much may be effected by this method in the hands of a skillful teacher, but a charlatan might make it an excuse for ignorance and neglect.

Among those who have improved the methods of teaching, we must mention Bell and Lancaster, the joint-discoverers of the method of mutual instruction, which, if it has not effected everything which its founders expected of it, has produced the system of pupil-teachers which is common in our schools. Froebel also deserves an honourable place as the founder of the Kindergarten, a means of teaching young children by playing and amusement. His plans, which have a far wider significance than this limited development of them, are likely to be fruitful of results to future workers.

The last English writers on education are Mr Herbert Spencer and Mr Alexander Bain, the study of whose writings will lead us in those regions of pedagogics which have been most recently explored. We need not follow Mr Spencer into his defence of science as the worthiest object of study, or in his rules for moral and physical training, except to say that they are sound and practical. In writing of intellectual education, he insists that we shall attain the best results by closely studying the development of the mind, and availing ourselves of the whole amount of force which nature puts at our disposal. The mind of every being is naturally active and vigorous, indeed it is never at rest. But for its healthy growth it must have something to work upon, and, therefore, the teacher must watch its movements with the most sympathetic care, in order to supply exactly that food which it requires at any particular time. In this way a much larger cycle of attainments can be compassed than by the adoption of any programme or curriculum, however carefully drawn up. It is no good to teach what is not remembered: the strength of memory depends on attention, and attention depends upon interest. To teach without interest is to work like Sisyphus and the Danaides. Arouse interest if you can, rather by high means than by low means. But it is a saving of power to make use of interest which you have already existing, and which, unless dried up or distorted by injudicious violence, will naturally lead the mind into all the knowledge which it is capable of receiving. Therefore never from the first force a child's attention; leave off a study the moment it becomes wearisome, never let a child do what it does not like, only take care that when its liking is in activity a choice of good as well as evil shall be given to it.

Mr Bain's writings on education, which are contained in some articles in the *Fortnightly Review*, and in two articles in *Mind* (Nov. 7, and vii.) are extremely valuable. Perhaps

the most interesting part of them consists in his showing how what may be called the "correlation of forces in man" helps us to a right education. From this we learn that emotion may be transformed into intellect, that sensation may exhaust the brain as much as thought, and we may infer that the chief duty of a schoolmaster is to stimulate the powers of each brain under his charge to the fullest activity, and to apportion them in that ratio which will best conduce to the most complete and harmonious development of the individual.

It seems to follow from this sketch of the history of education that, in spite of the great advances which have been made of late years, the science of education is still far in advance of the art. Schoolmasters are still spending their best energies in teaching subjects which have been universally condemned by educational reformers for the last two hundred years. The education of every public school is a farrago of rules, principles, and customs derived from every age of teaching, from the most modern to the most remote. It is plain that the science and art of teaching will never be established on a firm basis until it is organized on the model of the sister art of medicine. We must pursue the patient methods of induction by which other sciences have reached the stature of maturity; we must discover some means of registering and tabulating results: we must invent a phraseology and nomenclature which will enable results to be accurately recorded; we must place education in its proper position among the sciences of observation. A philosopher who should succeed in doing this would be venerated by future ages as the creator of the art of teaching.

It only remains now to give some account of the very large literature of the subject.

The history of education was not investigated till the beginning of the present century, and since then little original research has been made except by Germans. Whilst acknowledging our great obligations to the German historians, we cannot but regret that all the investigations have belonged to the same nation. For instance, one of the best treatises on education written in the 16th century is Mulcaster's *Position*, which has never been reprinted, and is now a literary curiosity.

Mangelsdorf and Ruhkopf attempted histories of education at the end of the last century, but the first work of note was F. H. Cn. Schwarz's *Geschichte d. Erziehung* (1813). A. H. Niemeyer, a very influential writer, was one of the first to insist on the importance of making use of all that has been handed down to us, and with this practical object in view he has given us an *Ueberblick der allgemeinen Geschichte der Erziehung*. Other writers followed: but from the time of its appearance till within the last few years, by far the most readable and the most read work on the history of education was that of Karl von Ranmer. Ranmer, however, is too chatty and too religious to pass for "wissenschaftlich," and the standard history is now that of Karl Schmidt. The Roman Catholics have not been content to adopt the works of Protestants, but have histories of their own. These are the very pleasing sketches of L. Kellner and the somewhat larger history by Stoeckl. When we come to writers who have produced sketches or shorter histories, we find the list in Germany a very long one. Among the best books of this kind are Fried. Dittes's *Geschichte* and Dröse's *Pädagogische Charakterbilder*. An account of this literature will be found in J. Chr. G. Schumann's paper among the *Pädagogische Studien*, edited by Dr Reiss. For biographies the pedagogic cyclopedias may be consulted, of which the first is the *Encyclopädie des gesammten Erziehungswesens* of K. A. Schmid, a great work in 11 or 12 vols. not yet completed, although the second edition of the early vols.

is already announced. The Roman Catholics have also begun a large encyclopædia edited by Rolfs and Pfister. No similar work has been published in France, but a *Cyclopædia of Education* in one volume has lately been issued at New York (Steiger,—the editors are Kiddo and Scherr), and in this there are articles by English as well as American writers. In French the *Esquisse d'un système complet d'Education*, by Th. Fritz (Strasbourg, 1841), has a sketch of the history, which as a sketch is worth notice. Jules Paroz has written a useful little *Histoire* which would have been more valuable if it had been longer.

In English, though we have no investigators of the history of education we have a fairly large literature on the subject, but it belongs almost exclusively to the United States. The great work of Henry Barnard, the *American Journal of Education*, in 25 vols., has valuable papers on almost every part of our subject, many of them translated from the German, but there are also original papers on our old English educational writers and extracts from their works. This is by far the most valuable work in our language on the history of education. The small volumes published in America with the title of "History of Education" do not deserve notice. In England may be mentioned the article on education by Mr James Mill, published in the early editions of the *Encyclopædia Britannica*, and Mr R. H. Quick's most excellent *Essays on Educational Reformers*, published in 1868. Since then Mr Leitch of Glasgow has issued a volume called *Practical Educationists*, which deals with English and Scotch reformers, as well as with Comenius and Pestalozzi. Now that professorships of education have been established we may hope for some original research. The first professor appointed was the late Joseph Payne, a name well known to those among us who have studied the theory of education. The professorship was started by the College of Preceptors. At Edinburgh and at St Andrews professors have since been elected by the Bell Trustees.

Valuable reports as to the state of education in the various countries that possess a national system were presented to the English Schools Inquiry Commission in 1867 and 1868, by inspectors specially appointed to investigate the subject. The reports on the Common School System of the United States and Canada by the Rev. James Fraser, on the Burgh Schools in Scotland by D. R. Fearon, and on Secondary Education in France, Germany, Switzerland and Italy, by Matthew Arnold, are included in Parliamentary Papers [3857]. 1867, and [3966 &c.], 1868.

The following is a list of some useful books on education generally.—Herbart, *Allgemeine Pädagogik*, Göttingen, 1806; Schwarz, *Erziehungslehre*, 2. Aufl. 1829; Diesterweg, *Wegweise für Deutsche Lehrer*, 1873; Niemeyer, *Grundsätze der Erziehung und des Unterrichts*, Halle, 1836; Beneke, *Erziehungs- und Unterrichtslehre*, 1832; Graefe, *Allgemeine Pädagogik*, 1845; Waitz, *Allgem. Pädagogik*, 1852; Herbert Spencer, *Education—Intellectual, Moral, and Physical*. On special points on the history of education:—Gruberger, *Erziehung und Unterricht in Classischer Alterthum*; A. Kapp, *Plato's Erziehungslehre*, Minden and Leipzig, 1838; *Die Bruderschaft des gemeinsamen Lebens*, by Delprat, translated into German, Leipzig, 1840; Hoppe, *Die Schulklassen des Mittelalters*, Marburg, 1860; *The Schools of Charles the Great*, by Mullinger, 1877; Rosmini, *Vite e scuola da Felice*, 1801; Weicker, *Die Schulklassen der Jesuiten*, Halle, 1863. The works of Comenius and other educationists are most easily accessible in the *Pädagogische Bibliothek*, edited by Karl Richter, Leipzig (now in course of publication); J. Ramsauer, *Kurze Skizze meines Pädagogischen Lebens*, Oldenburg, 1838; H. Blochmann, *Heinrich Pestalozzi*, Leipzig, 1846; Krieger, *Johann's Lebens-Geschichte*, Zweibrücken, 1830.

To these may be added:—M. Bréal, *Quelques révisions sur l'Instruction publique*, 1874; Dr James Donaldson's *Lectures on Education*, 1874; A. Droc's *Charakteristiken*, 4th ed., 1872; Dittus, *Gesch. de l'Éducation*, 3d ed., 1873; M. and R. L. Edgeworth's *Practical Education*, 1st ed., 1778; Manthol-Bulow's *Erziehungsroman*, F. Frödel, translated by Mrs Horace Mann, Boston, U.S.; R. de Guimp's *Histoire de Pestalozzi*, 1874; Isaac Taylor *Home Education*; F. H. Kohl's

Grundzüge der evangelischen Volksschulerziehung, Breslau, 1873. L. Kellner's *Erziehungsgeschichte*; H. Lantome, *Histoire de l'Enseignement secondaire en France*, 1874; J. S. Mill, *Inaugural Address at St Andrews*; Pullans's *Contributions to Education*; J. Paroz, *Histoire universelle de la pédagogie*; Rollin, *Traité des Études*; Krusi, *Life of Pestalozzi*; Dr Arnold, *Miscellaneous Works*, Dr Stow, *Training System*, 11th ed., 1859, A. Stockl's *Lehrbuch der Geschichte der Pädagogik*, Mainz, 1876, T. Tate, *Philosophy of Education*, Abbot's *Teacher*; F. A. Wolf, *Ueber Erziehung*, edited by Korte, 1835. L. Wiese, *German Letters on English Education*, 1877; Bohn, *Kurzgefasste Geschichte der Pädagogik*. (O B)

Law Relating to Education.

To the foregoing historical statement may be added some account of the different systems of education administered by statute in the United Kingdom:—

England.—Until quite recently there was no public provision for education in England, and even now it is only the elementary education of the people that can be said to be regulated by the law. Parliament has indeed taken cognizance of the institutions founded for the higher education. The universities and the endowed schools have been enabled by various statutes to adapt themselves more completely to the wants of the times; but they still retain their character of local, and one might almost say private, corporations. Their administration is subject to the control of no state authority, and in districts where such institutions do not exist there is no public provision for supplementing the deficiency. Elementary education, until the Act of 1870, was in the same way dependent on voluntary enterprise or casual endowment.

The first approach to a public system of education was by means of grants in aid of private schools, administered by a committee of the Privy Council. This system is not superseded by the Education Act of 1870, but means are taken to ensure the existence in every school district of a "sufficient amount of accommodation in public elementary schools." The school district is the borough or parish, except in the case of London and Oxford. When the amount of school accommodation in a district is insufficient, and the deficiency is not supplied as required by the Act, a school board shall be formed and shall supply such deficiency. Every elementary school is a public school in the sense of the Act if it is conducted according to the regulations in section 7, which in substance are:—

1. It shall not be required, as a condition of any child being admitted into, or continuing in the school, that he shall attend or abstain from attending any Sunday school, or any place of religious worship, or that he shall attend any religious observance or any instruction in religious subjects, in the school or elsewhere, from which observance or instruction he may be withdrawn by his parents, or that he shall, if withdrawn by his parents, attend the school on any day set apart for religious observance by the religious body to which his parent belongs.

2. Time for religious observance or instruction in the school must be at the beginning or end of school meeting, and must be shown in a time table conspicuously posted in the school.

3. School must be open to inspection, except that the inspector is not to inquire into religious knowledge.

4. School must be conducted in accordance with the conditions required to obtain a parliamentary grant.

When the Education Department are satisfied after inquiry that the supply of public elementary schools as thus defined is in any district insufficient, they may cause a school board to be formed, as they may also (1) when application is made to them to that effect by the persons who would be the electors if there were a school board (in a borough by council), and (2) when they are satisfied that the managers of an elementary school are unwilling or unable to maintain it, and by its discontinuance the supply for the district will become insufficient. The body of the Act describes the constitution, powers, duties, and revenues of school boards, as in the following brief summary:—

1. *Constitution*.—The school board is a corporation with perpetual succession and common seal, and power to hold land with out licence in mortmain. It is elected by the burgesses in a borough, and by

Parliamentary grants are to be made (1) to school boards, (2) to the managers of any school which is efficiently contributing to secular education. No grant shall be made in respect of (1) religious instruction, (2) new schools, not being public schools, unless it appears that they are required, regard being had to the religious belief of the parents of the children for whom they are intended, or other special circumstances of the locality. Section 68 is the conscience clause, and it may be mentioned that the preamble of the Act states that it is expedient that managers of public schools should be at liberty to continue the custom of giving "instruction in religion to children whose parents did not object, with liberty to parents, without forfeiting any of the other advantages of the schools, to elect that their children should not receive such instruction." Section 69 imposes on parents the duty of providing elementary instruction for children between five and thirteen, and the parochial board shall pay the fee for poor parents. Defaulters may be prosecuted; and persons receiving children into their houses or workshops shall be deemed to have undertaken the duties of parents with reference to the education of children. A certificate of the child's proficiency by an inspector protects the parent or employer from proceedings under the Act. Other clauses relate to the non-educational duties imposed by various Acts on schoolmasters (now transferred to registrars), and to the "Schoolmasters' Widows' Fund," to which now masters are not required to contribute.

The Education Board, continued by Order in Council to 6th August 1877, has been further continued by statute to 6th August 1878.

Ireland.—The public elementary school system depends on grants made to the lord-lieutenant, to be expended under the direction of commissioners nominated by the Crown, and named "The Commissioners of National Education." The commissioners were incorporated by this name in 1845, with power to hold land to the yearly value of £40,000. The following statement, taken from the rules and regulations of the commissioners appended to their report for 1873, exhibits the leading points of the system as contrasted with that now established in England and Scotland.

"The object of the system of national education is to afford combined literary and moral and separate religious instruction to children of all persuasions, as far as possible in the same school, upon the fundamental principle that no attempt shall be made to interfere with the peculiar religious tenets of any description of Christian pupils. It is an earnest wish of Her Majesty's Government and of the commissioners that the clergy and laity of the different religious denominations should co-operate in conducting national schools."

The commissioners grant aid either to vested schools (i.e., schools vested in themselves, or in local trustees to be maintained by them as national schools) or to non-vested (i.e., private schools), and the grant may be towards payment of salary or supply of books, or, in the case of vested schools, towards providing buildings.

The local government of the national schools is vested in the local patrons or managers thereof, and the local patron is the person who applies in the first instance to place the school in connection with the board, unless otherwise specified. The patron may manage the school by himself or by a deputy. If the school is controlled by a committee or vested in trustees, they are the patrons. A patron may nominate his successor, and in case of death, his legal representative if he was a layman, and his successor in office if he was a clerical patron, will be recognized by the commissioners. The local patrons have the power of appointing and removing teachers, subject to a rule requiring three months' notice to the teacher. Every national school must be visited three times a year by inspectors.

In non-vested schools, the commissioners do not in general make any conditions as to the use of the building after school hours; but no national school house shall be employed at any time, even temporarily, as the stated place of divine worship of any religious community, and no grant will be made to a school held in a place of worship. In all national schools there must be secular instruction four hours a day upon five days in the week. Religious instruction must be so arranged that each school shall be open to

the children of all communions, that due regard be had to parental right and authority, and that accordingly no child shall receive or be present at any religious instruction of which his parents or guardians disapprove. In non-vested schools it is for the patrons and local managers to determine whether any and what religious instruction shall be given. In all national schools, the patrons have the right to permit the Scriptures to be read; and in all vested schools they must afford opportunities for the same, if the parents or guardians require it. (E. R.)

EDWARD, or EADWARD I., king of the Anglo-Saxons, was the eldest son of Alfred the Great, and succeeded his father, by the voice of the Witan, 26th October 901. He was then about thirty years of age, and had already in 893 distinguished himself by inflicting a disastrous defeat on the Danes at Farnham. His election to the throne was disputed by his cousin Ethelwold, who, leaguely himself with the Danes of Northumbria, waged with varying success a civil war of four years' duration. It was brought to a close in 906 by Ethelwold's death in battle, when Edward concluded a peace with the East Anglians and Northumbrians. The pacification was not, however, of a very satisfactory nature, and was not of long continuance, for in 910 Edward "sent out a force of West Saxons and Mercians, who greatly spoiled the army of the north," and in 911 the Danes, receiving large reinforcements from France, made repeated attacks on Wessex and Mercia. Against this common enemy Edward and his sister Ethelfleda, who became "lady of Mercia" in 912, formed conjoint measures. Ethelfleda drove the Danes from Mercia, and to secure her conquests erected the fortresses of Bridgenorth, Stafford, Tamworth, and Warwick; while Edward, by adopting the same methods in East Anglia and Essex, gradually accomplished the complete subjugation of the Danes. On the death of Ethelfleda in 922 he annexed Mercia to his own crown, and became king of all England south of the Humber. But this was not the whole result of his victories, for the Danes of Northumbria, the Welsh, the Scots, and the Britons of Strathclyde, either from dread of his power or from desire for his protection, voluntarily chose him to be their "father and lord." He died in 925. Inferior to his father in the higher moral and intellectual qualities, Edward manifested gifts superior to his as a legislator and warrior, and under him the Anglo-Saxon rule attained a fame and influence to which it had never before made a near approximation.

EDWARD, or EADWARD II., surnamed the Martyr, an Anglo-Saxon king, succeeded his father Edgar in 975, at the age of about thirteen years. He was the elder son of Edgar, and is said to have been recommended by him as his successor; but the party in the state opposed to the monks supported nevertheless the claims of his younger brother Ethelred, son of Elfrida, and only seven years of age. The influence of Dunstan was, however, sufficiently great to overbear all opposition, and in a somewhat summary fashion he presented Edward to the Witan at Winchester, and consecrated him king. During his short reign the only circumstances worthy of notice are the quarrels between the two parties in the state, and the rapid decline of the authority of Dunstan and the monks. The death of Edward, which occurred in 978, was the result of a base act of treachery on the part of Elfrida. He was returning exhausted from the chase at Wareham when he was lured to her residence, and was stabbed in the back while partaking of hospitality before her palace gate.

EDWARD, or EADWARD III., king of the Anglo-Saxons, surnamed, on account of his reputation for superior sanctity, the Confessor, was the son of Ethelred II. and Emma, daughter of Richard I. of Normandy, and was born at Islip, Oxfordshire, probably in 1004. On the election of Swend to the throne of England in 1013, Emma with

her husband and family took refuge in Normandy; and Edward, notwithstanding the marriage of Emma to Canute in 1017, continued to reside at the Norman court, until he was recalled to England by Hardicanute in 1041. Hardicanute died in 1042, and "before the king was buried, all folk chose Edward to be king at London;" but partly from his own unwillingness to accept the crown, and partly from the opposition of the Danes who came into England with Canute, his coronation did not take place till April 1043. The chief agent in overcoming his scruples, and in quelling all murmurs of opposition against his election, was Godwin the West Saxon earl, whose influence was at that time paramount in England. The exact nature of the relations between Godwin and Edward has been the subject of considerable discussion, but the most probable view of the matter is that, until after the marriage of Edward to Edgitha, daughter of Godwin, in 1045, these were on the whole cordial and friendly, but that gradually the king's preference of Normans to Anglo-Saxons, his necessary friendship with Leofric of Mercia and Siward of Northumbria, and his growing dread of Godwin's ambitious character, led to misunderstanding and distrust. It was, probably, at the instigation of Godwin that Edward, on his accession to the throne, deprived his mother Emma of her possessions, and caused her to live in retirement at Winchester, and that he banished from the kingdom the chief Danish partisans who opposed his election. For the first eight years his reign was comparatively tranquil, the only circumstances worthy of mention being a threatened invasion by Norway, the ravages committed by pirates in Kent and Essex, and the outlawry of Sweyn, son of Godwin, for the seduction of the abbess of Leominster. In 1051, Eustace, count of Boulogne, in endeavouring to quarter his followers on the town of Dover, was resisted by the burghers, and a quarrel ensuing, several Normans were slain. The king, on hearing Eustace's account of the affair, without further inquiry, commanded Godwin to chastise the town by military execution. Godwin demanded a trial; but the king, incited it is said by Robert, archbishop of Canterbury, summoned a meeting of the Witan at Gloucester, not for the purpose of inquiring into the affair at Dover, but to pass judgment on Godwin for his contumacy. Ultimately, Godwin thought it prudent to leave the country and take refuge in Flanders. It was during his absence that William, duke of Normandy, visited England, and if this prince did not then receive the promise of the crown from Edward, his ambition to possess it and his hopes of success were doubtless confirmed by his visit. There seems to have been general regret at Godwin's absence; and encouraged by the assurances he received from England, he gathered a fleet, and uniting with Harold, appeared before London. The king endeavoured to oppose him, but was obliged to yield to the wishes of his subjects, and Godwin and his sons were reinstated in their possessions. When her father left England, Edgitha had been deprived of her property and sent to the royal abbey of Wherwell, but on his return she was restored to her former position. Godwin died in 1053, and after his death Harold attained to great influence, and virtually ruled the kingdom in the name of Edward. Towards the end of 1065 Edward's health began rapidly to fail. He had rebuilt the ancient abbey of Westminster, and his only wish was to be present at its consecration, which was to take place on the 28th December, but over-exertion on some previous festival days was too much for his remaining strength. His share in the ceremony had to be performed by deputy, and he died 5th January 1066. It was his last wish that Harold should succeed him on the throne. The virtues of Edward, it has been said, were monastic rather than kingly. His aims were just and righteous, and he showed his interest in his subjects by the

preparation of a digest of the laws of the kingdom, and by the repeal of the Danegeld, or war tax; but his weak character and his feeble interest in worldly matters caused the real government of the kingdom during his reign to be placed almost entirely in the hands of favourites.

See Palgrave's *History of the Anglo-Saxons*, Green's *History of the English People*, and especially Freeman's *Norman Conquest*, vol. II.

EDWARD I. (1239-1307), king of England, was the son of Henry III. of England, and of Eleanor, daughter of the count of Provence, and was born at Westminster, June 16, 1239. In 1252 he was named governor of Gascony in room of Simon de Montfort, with whom Henry was dissatisfied; and in 1254, by his marriage with Eleanor, daughter of Alphonso X. of Castile, he secured to the English for a time undisputed possession of that province. At the battle of Lewes, 13th May 1264, Edward, by the impetuosity of his attack, at first defeated the barons with great slaughter, but by his too great rashness in pursuit failed to give the king proper support in another part of the field, and was thus the cause ultimately of the utter rout of the royal forces. He was taken prisoner, but escaping by a clever stratagem, he joined with the earl of Gloucester, and inflicted a disastrous defeat on De Montfort and his sons at Evesham, August 3, 1265. In 1269, at the request of the Pope, he undertook a crusade to the Holy Land. He reached it in 1270, and in 1271 he captured Nazareth and massacred all the Turks found within its walls. In revenge, perhaps, for this act, an assassin, on June 12, 1272, stabbed him in three places with a poisoned arrow; but his vigorous constitution triumphed over his injuries and he completely recovered. In the same year his father died, and he was proclaimed king. He had arrived at Sicily when the news reached him, but instead of going direct to England, he crossed over to Italy, and thence into France, where in a tournament his followers quarrelled with those of the count of Chalons, and he slew the count in single combat. He landed in England August 2, 1274, and was crowned on the 19th. In October of the same year he issued writs to inquire into the state of the realm, and the next year there were passed the laws called the Statutes of Westminster, which reformed many of the abuses of the feudal system, secured freedom from undue influence in the election of sheriffs and other justices, and threatened with penalties certain oppressive acts on the part of the barons. In 1277 he conquered Wales and caused Llewelyn to sue for peace; but in 1280, a Welsh war again broke out, which continued till the death of Llewelyn in 1282. Edward's plan to obtain money for the expenses of this war, by summoning for consultation in 1283 representatives of the shires, the boroughs, and the church, was the germ of the English House of Commons, although the first properly constituted Parliament did not meet till 1295. A less creditable method of raising money was the banishment, in 1280, of the Jews from England, on condition that the clergy and laity submitted to a tax of a fifteenth. Two other important decisions were the consequence of his money difficulties:—in 1297 he refused submission to the bull of Boniface VIII. forbidding the clergy to be taxed on their ecclesiastical revenue, and in 1299 he was obliged to confirm the charters conferring on the people the right to fix their own taxation. In 1290 Queen Eleanor died, and in 1293 Edward entered into negotiations for a marriage with Margaret, sister of Philip IV. of France; but on account of an act of treachery on the part of the French, these negotiations were broken off for a time, and the marriage did not take place till 1299. From 1295 the affairs of Scotland occupied his chief attention. In 1292 he had decided the claims of the candidates for the Scottish crown

in favour of Baliol, on condition that the latter acknowledged him as lord paramount, and on the breaking out of war with France he demanded his assistance. On Baliol's refusal, and on learning that he had entered into a treaty with France, Edward in 1296 captured Berwick, defeated the Scots at Dunbar, took the castles of Roxburgh, Jedburgh, Edinburgh, Dumbarton, and Stirling, and, receiving at Perth Baliol's unconditional surrender, sent him prisoner to the Tower. In 1297 Wallace headed a rebellion of the Scots, and defeated the English with great slaughter at the battle of Stirling bridge; but next year the Scots suffered an overwhelming defeat at Falkirk, and only prevented the further success of the English by laying waste their own country. In 1299 and 1300 Edward's attempts at invasion met with little success on account of opposition from his barons. In 1301 he invaded Scotland for the fifth time, but at the request of the king of France granted it a truce. In 1304 he compelled its submission, and excepted from the amnesty granted to the Scotch nobles Sir William Wallace, who was captured and executed in 1305. In 1307, to avenge Bruce's murder of Comyn and his attacks on the English, Edward resolved on a seventh invasion, and, though in great bodily weakness, determined to lead his army in person; but his almost unexampled labours had already undermined his vigorous health, and he died 7th July 1307, at the village of Burgh-on-the-Sands, on the fifth day of his march northwards from Carlisle. He had given orders that his dead body should be carried before the army until his enemies were conquered; but his son Edward made no endeavour to fulfil his wish. The body was escorted to Waltham, and was buried at Westminster on the 27th October. In Edward were united in a rare degree both the physical and mental qualities of a great general; and he is one of the few English kings, and perhaps the first, who can lay claim to the higher qualities of statesmanship. The measures which he passed for the government of his own kingdom, and the concessions he made to the demands of his subjects, almost entitle him to be called the founder of England's constitutional freedom; while the far-seeing wisdom of his foreign policy was shown by his sacrificing his influence in France in order to quell the opposition to his authority in Scotland. That his claims on Scotland were altogether just can scarcely be affirmed; but that he clearly saw the necessity of a union of Scotland and England, and devoted his whole efforts to the attainment of this end, is perhaps his highest title to honourable remembrance. His harsh manner of attaining his end, and the cruel punishments he exercised on those who sought to thwart his efforts, may be excused partly on account of the times in which he lived, and partly as arising from the just vexation of a stern and eager nature; and they are somewhat counter-balanced by the righteousness and clemency with which he governed Scotland at the periods when it was under his rule.

See Hallam's *Middle Ages*; Pearson's *History of England during the Early and Middle Ages*, vol. II.; Longman's *Lectures on the History of England*, vol. I.; Stubbs's *Early Plantagenet Kings*; Hill Burton's *History of Scotland*, vol. II.; and Green's *Short History of the English People*.

EDWARD II. (1284-1327), king of England, fourth son of Edward I. and of Eleanor, was born at Carnarvon, April 25, 1284, and became heir-apparent in 1285. His first title was earl of Carnarvon, but in 1301 he was created earl of Chester and prince of Wales. His personal character, and the whole tenor and tendency of his reign, may perhaps be best described as the opposite of those of his father. Though not the slave of any of the worst vices, and not without natural abilities, he was weak, indolent, and faithless; and his utter incompetence for the position in which fortune had placed him requires no other proof than the fate which

finally overtook him. His first acts after the death of his father foreshadowed his future career. He at once recalled Piers Gaveston, a favourite whom his father had banished from the court, and created him earl of Cornwall, caused his father's body to be buried at Westminster, and, after rejoining the army for a few days, returned again to London, and for six years made no serious effort to prosecute the war with Scotland. Previous to his coronation he went to France to be married to Isabella, daughter of Philip II.; and by appointing Gaveston guardian of the kingdom during his absence, and leading him with honours and presents on his return, he roused the animosity of the nobles to such a height that it was only on his promising to agree to certain demands that might be submitted to him at a future Parliament, that they consented to his coronation. It took place 25th February 1308. Until the nobles rose in rebellion in 1312, and executed Gaveston at Warwick castle, the favourite formed a perpetual subject of dispute between the nobles and the king, and was alternately banished and recalled according to the king's exigencies. In 1311 Parliament confirmed the report of the "Committee of Ordinances" appointed to reform the abuses of the administration. The king nominally agreed to act in accordance with the report, but by a saving clause secured to himself full liberty to evade the principal enactments, the result of which was a series of quarrels with the nobles, becoming more serious each successive time, followed by reconciliations increasing gradually in hollowness till the end of his reign. Robert Bruce took full advantage of the internal difficulties of England, and in 1314 had reconquered the principal strongholds of Scotland with the exception of Stirling castle. For its relief Edward raised an army of 100,000 men, but suffered a ruinous defeat at the battle of Bannockburn, 24th June 1314. Edward made no further effort of importance against the Scots till 1319, when he besieged Berwick, which Bruce had taken, but was compelled to raise the siege, and concluded a two years' truce with Scotland. After the death of Piers Gaveston, the place of favourite with the king was occupied by Hugh Despenser. He was banished by Parliament in 1321, but soon returned; and, provoked at this, the barons under Lancaster declared war, but were defeated and Lancaster executed in March 1322. In 1323 a fourteen years' truce was concluded with Scotland. In 1324 Edward was persuaded to send the queen to France in order to settle some disputes with the French king. She succeeded in her mission, but refused to return home, on account, she affirmed, of previous ill-treatment by her husband, although doubtless intrigues with Roger Mortimer had something to do with her refusal. From France she went to Flanders, and, raising a small army against the king, landed at Orwell in Suffolk, 22d September 1326. The whole nation flocked to her standard, Despenser was executed, and young Edward was appointed guardian of the kingdom. In 1327, the king was formally deposed by Parliament, and his son elected in his stead. A plot was formed against the deposed monarch in the same year, and he was murdered with great cruelty at Berkeley Castle on the 27th September. (See the same writers for this reign as for the last.)

EDWARD III. (1312-1377), king of England, the eldest son of Edward II. and of Isabella, was born at Windsor, November 13, 1312. He was appointed guardian of the kingdom October 26, 1326, and received the crown February 1, 1327. On the 24th January 1328 he was married to Philippa, daughter of the count of Hainault. During his minority the government of the kingdom was intrusted to a body of guardians with Henry of Lancaster at their head, but was virtually usurped by Roger Mortimer, until the king, irritated by his arrogance, caused him to be

seized at Nottingham on the 15th October 1330, and conveyed to the Tower. He was executed at Tyburn on the 29th November. It is said to have been chiefly through Mortimer's influence that, on the 24th April 1328, a peace was concluded between England and Scotland, the chief provisions of which were that the Scots agreed to pay England the sum of £20,000, and that Edward agreed definitely to recognize the independence of the Scotch crown. The treaty was very unpopular in England, and it is not surprising, therefore, that, when Edward Baliol in 1332 made his attempt to mount the Scotch throne, Edward III. gave him indirect assistance, and that after Baliol's dethronement in 1333 an invasion of Scotland was resolved on. On July 19 Edward defeated the Scots at the battle of Halidon Hill, and receiving as the result of his victory the submission of the principal Scotch nobles, he annexed the whole of Scotland south of the Forth to his own crown, and allowed Baliol to reign over the remainder as titular king. Soon after, Baliol was again a fugitive, but was again aided by Edward to mount a nominal throne. After a short period of peace Edward in July 1336 ravaged and burned Scotland as far as Aberdeen, but growing complications with France compelled him in the same year to return to England. Though he professed to have a claim, through his mother, on the French throne against Philip of Valois, that claim was left in abeyance until several acts of aggression on the part of Philip brought about a rupture between the two kings. The count of Flanders, at Philip's instigation, had broken off commercial relations with England, French privateers were daily committing ravages on English commerce, Aquitaine was continually threatened by desultory attacks; and Philip, though he hesitated to accept the responsibility of being the first to declare war, scarcely attempted to conceal his endeavours to throw that responsibility on Edward. Edward sailed for Flanders July 16, 1338, and at Coblentz held a conference with the emperor Louis V., at which the latter appointed him his vicar-general, and gave orders for all the princes of the Low Countries to follow him in war for the space of seven years. In 1339 Edward laid siege to Cambrai, but soon afterwards raised the siege and invaded France. Philip advanced to meet him, but declined battle, and Edward concluded his first campaign without achieving anything to compensate him for its cost. In 1340 he defeated the French fleet before Sluys, and after landing in France laid siege to Tonnai, but before he succeeded in capturing it he was induced through money difficulties to conclude a truce of nine months with France. In 1342 a truce for two years was concluded between England and Scotland, and at the end of the same year Edward again set out on an expedition against France, but at the intercession of the Pope he agreed to a truce. Shortly after his return to England a great tournament was held by him at Windsor in memory of King Arthur. In 1346 he set sail on the expedition which resulted in the great victory of Crécy and the capture of Calais; and in 1348 he again concluded a truce with France. This year and the following are darkly memorable in English annals from the outbreak of the "black death," which spread terror and desolation throughout the whole country, but on account of the reduction it made in the population, was the ultimate cause of the abolition of serfdom and villanage in England. From this time Edward as a warrior retires somewhat into the background, his place being taken by the prince of Wales (See EDWARD THE BLACK PRINCE), who in 1356 won the battle of Poitiers, and took King John prisoner. In 1359 Edward again invaded France, and in 1360 he signed the peace of Bretigny, according to which the French agreed to pay for King John a ransom of three million crowns, and Edward renounced his title to

the throne of France, but retained his full sovereignty over the whole of the ancient duchy of Aquitaine, the counties of Ponthieu and Guignes, and the town of Calais. Peace was again broken in 1369 by Charles of France, and when he concluded a truce with England in 1375 all of France that remained in Edward's hands was Bayonne and Bordeaux in the south, and Calais in the north. The last years of Edward's reign form a sad and gloomy close to a career which had had a vigorous and energetic commencement, and had afterwards been rendered illustrious by great achievements. His empire in France was virtually overthrown; the vast expenditure which had had such a fruitless result was sorely burdening his subjects, and awakening increasing discontent; and he himself, through the gradual decay of his mental faculties, had become a mere tool in the hands of Alice Perrers and of ministers whose only aim was their own aggrandizement. In 1367 the "Good Parliament" virtually seized the helm of the state from the hands of the king and his ministers. It compelled Alice Perrers to swear never to return to the king's presence, suspended the ministers Latimer and Lyons, protested against the means then adopted for raising taxes, and demanded a vigorous prosecution of the war. The Black Prince was the chief agent in urging these reforms, but his death, in the midst of the Parliament's deliberations, for a time rendered almost abortive the good work he had begun. Edward died 21st June 1377. The splendour of his reign belongs properly rather to the people than to the monarch. Both in his home and foreign relations he showed considerable prudence and sagacity, and he may be allowed the merit of having endeavoured as much as possible to keep on good terms with his subjects; but under him the progress of constitutional reform was due either to his money difficulties or to events entirely beyond his control. Although endowed with high courage and daring, there is no proof that he possessed more than average ability as a general. His expeditions were planned on a scale of great magnificence, but he entered on his campaigns without any definite aim, and his splendid victories were mere isolated achievements, won partly by good fortune, but chiefly by the valour of Welsh and Irish yeomen and the skill of English archers.

See *History of Edward the Third*, by W. Longman (1869); *Edward III.*, by Rev. W. Warburton, M.A. (1876); *Pearson's England in the Fourteenth Century* (1876), and essay on Edward III., by E. A. Freeman (*Essays*, first series).

EDWARD IV (1441-1483), king of England, was the second son of Richard duke of York, and was born at Rouen, April 29, 1441. His father was appointed protector of the kingdom during the incapacity of Henry VI., and having in 1460 laid claim to the throne as a descendant of Edward III., was named by Parliament successor of Henry VI. on condition that he allowed Henry to retain his throne. As an heir had been born to the king, it was only natural that Queen Margaret should seek to resist this proposal. She accordingly raised an army against the duke of York, and he was defeated and slain at the battle of Wakefield, December 30, 1460. Edward, who was at that time in Wales, on hearing of his father's death resolved to avenge it, and gathering a mixed army of Welsh and English, defeated the earls of Pembroke and Ormond at Mortimer's Cross in Hereford, February 7, 1461. On February 17, Queen Margaret defeated the Yorkists at St Albans; but Edward, notwithstanding her victory, having united his forces with those under Warwick entered London, and, being received by the citizens with loud shouts of welcome, was proclaimed king 4th March 1461. But he could not permit himself to enjoy his dignities in idle security. King Henry had escaped and joined the army of the queen, which, having withdrawn to the north,

was to the number of about 60,000 encamped at Towton, about eight miles from York. Here Edward and Warwick met the queen's forces, and a battle of great obstinacy ensued, which, notwithstanding the arrival of a reinforcement to Margaret in the middle of the battle, ended in her utter defeat. Henry and Margaret fled to Scotland, and on the 28 June Edward was crowned at London. Margaret afterwards escaped to France, from which country in 1462 she made two separate attempts to retrieve the fallen fortunes of her house, but these, as well as one made by Henry in 1464, proved utterly abortive. In May 1461 Edward was secretly married to Elizabeth, daughter of Richard Woodville, Lord Rivers, and widow of Sir John Gray; and having in the September following publicly acknowledged her as his queen, he grievously disappointed and displeased his chief supporter, the earl of Warwick, who had been negotiating for the marriage of Edward with the sister of Louis XI. of France. Though from this time secretly bonding all his energies to accomplish Edward's overthrow, Warwick skilfully concealed not only his intentions but even his share in overt acts; and it was not till 1469 that, receiving intelligence of the success of an insurrection secretly fomented by him in Yorkshire, he showed his hand by taking the king prisoner near Coventry. Shortly after, Edward either escaped or was allowed his freedom; and in 1470 he defeated the rebels near Stamford, and compelled Warwick to make his escape to France. Here the earl, through the good offices of Louis, was reconciled with Queen Margaret, and agreed to invade England in behalf of her husband. Landing at Dartmouth, he soon had an army of 60,000 men. Edward, taken by surprise and unable to raise a force sufficient to oppose him, fled to Holland; and Warwick, having released Henry, again got him acknowledged king. Edward in his turn adopted the tactics that had been successful against him. In 1471 he landed at Ravenspur, and professing at first to resign all claims to the throne, and to have no further aim than merely to recover his inheritance as duke of York, he soon collected sympathizers, and then, throwing off all disguise, issued proclamations against Henry and Warwick. He marched without opposition direct to London, and after entering it and taking Henry prisoner, advanced against the army which had been collected to oppose him. The encounter took place at New Barnet, April 14, when the party of Warwick were defeated and Warwick himself was slain. On the same day Margaret with her son Edward, now eighteen years of age, had landed at Weymouth, but on May 4 she was defeated at Tewkesbury and taken prisoner. Her son either perished in battle, or was slain shortly afterwards by the order of the king; and her husband Henry died in the Tower on May 21, the evening of the day on which Edward re-entered London. Secure at home, Edward now turned his thoughts on foreign conquest. In 1475 he formed an alliance with Charles of Burgundy against Louis, but on landing on the Continent with a large army he learned that the duke and Louis had come to an understanding, and prudence compelled him to enter into a seven years' treaty with the power he had hoped to conquer. Shortly after this, the duke of Burgundy having died, Clarence, the brother of Edward, wished to marry Mary, the duke's daughter and heiress; but Edward, perhaps on account of chagrin at the former deceit of her father, refused his consent to the suit. Exasperated at his brother's conduct, Clarence took no pains to conceal his anger, and Edward thought it necessary to impeach him of treason before the House of Lords. He was condemned to death, February 7, 1478, and on February 17 was executed in the Tower, but with so great secrecy that the manner of his death is unknown. Edward died April 9, 1483. The beauty of his person and the freedom of his

manners rendered Edward a great favourite with the lower and middle classes, but there appears to have been little in his character to awaken real esteem. He had certainly an ability for subtle scheming and intrigue, but his memory is connected with no act conferring any benefit of importance on his country, and it is tarnished by several deeds of ruthless cruelty, and by the helpless self-indulgence into which he sank during his later years. On account of the unsettled nature of the country during his reign, the influence of Parliament on the affairs of the kingdom became virtually suspended; while the antipathy and contentions between the two parties of the nobles made it almost a necessity that that party which supported the king should be unable to present any strong resistance against undue exercise of authority on his part. The result was the inauguration of that form of despotism known as the New Monarchy.

EDWARD V. (1470-1483), king of England, was the son of Edward IV. and of Elizabeth, and was born in the sanctuary of Westminster Abbey, November 4, 1470. As soon as Edward IV. was dead his brother Richard, duke of Gloucester (see RICHARD III.), acting so far in accordance with the late king's wishes, secured possession of the person of the young king, and was appointed by Parliament protector of the realm. He had previously arrested Earl Rivers, the young king's uncle, and Lord Richard Gray his half-brother, and his next step was to accuse Lord Hastings, president of the royal council, of designs on his life, and to have him executed almost immediately afterwards on Tower Green. The way being now cleared for a full declaration of his designs, he caused it to be decided at a meeting of the Lords and Commons that the marriage of Edward IV. had been invalid on account of the existence of a precontract; and, receiving a petition to act in accordance with this decision and assume the crown, he after a very slight reluctance consented to do so. Edward V. and his brother were confined in the Tower. Shortly after it was known that they were dead, but though it was the general conviction that they had been murdered, it was not till twenty years afterwards that the manner of their death was discovered. Braekenbury, the constable of the Tower, had refused to obey the command of Richard to put the young princes to death, but complied with a warrant ordering him to give up the keys of the Tower for one night to Sir James Tyrrel, who had agreed to provide for the accomplishment of the infamous act. He gave admittance to two assassins hired by himself, who smothered the two youths under pillows while they were asleep.

For Edwards IV. and V. see Green's *Short History of the English People*, the *Houses of Lancaster and York*, by James Gairdner, and "König Richard III." in Paul's *Aufsätze zur Englischen Geschichte*.

EDWARD VI. (1537-1553), king of England, was the son of Henry VIII. and of Jane Seymour, and was born at Hampton Court, 12th October 1537. "Till he came to six years old," he says in his journal, "he was brought up among the women." He was then transferred to the direction of several masters, who instructed him in Latin, Greek, French, philosophy, and divinity. In his tenth year he was created prince of Wales and duke of Cornwall, and very shortly afterwards he succeeded to the throne on the death of his father, 28th January 1547. The will of Henry, for the protection of the young king, had named merely a council of regency, but that council immediately chose Edward, earl of Hertford, as protector, and on the 16th February ordered that he should be created duke of Somerset. The leanings of the protector were strongly Protestant, and he inaugurated his protectorate by the repeal of various Acts whose tendency was to support the waning influence of the Church of Rome, and by additional

legislation in favour of Reformation principles. Though England was in a somewhat unsettled state, this did not prevent him from planning an expedition against Scotland, on account of that power refusing to fulfil a former treaty by which a marriage had been agreed upon between Mary Queen of Scots and Edward. He defeated the Scots at the battle of Pinkie Cleugh, September 10, 1547, and next year captured Haddington; but, on account of growing dissensions at home, he was compelled to give up all further attempts against Scottish independence. His brother, who had been created Lord Seymour of Sudeley and made lord admiral of England, was suspected of being at the head of a plot to overturn his authority, and with something of bravado admitted as much as was sufficient to criminate himself, although he refused to answer in regard to the more serious charges. In the House of Lords a bill was framed against him which passed the House of Commons almost unanimously, and, it being assented to by the king shortly afterwards, he was executed on Tower Hill, March 20, 1549. In the following summer the distress consequent on the depreciation of the currency and the wasteful expenditure of the court awakened a general discontent, which in different parts of the kingdom broke out into open insurrection. The protector, instead of repressing the rebellion by vigorous measures, gave considerable concessions to the demands of the populace, his sympathy with whom he openly admitted. By such an avowal he necessarily alienated the nobility, and they speedily planned his overthrow. The council, headed by Dudley, earl of Warwick, declared against him, deposed him, and imprisoned him in the Tower, October 14, 1549. He regained his freedom shortly afterwards, but a plot which he was concocting for the overthrow of Warwick having prematurely come to light, he was again arrested in 1551, and being convicted of high treason, he was executed on Tower Hill, January 22, 1552. The king, who, except where his religious convictions were concerned, was a mere puppet in the hands of the faction which at any time was paramount, yielded his assent to the execution, apparently without any feelings of compunction. Warwick, some time before this created duke of Northumberland, now exercised absolute sway over the affairs of the kingdom, but he was hated by the populace, and distrusted even by the friends who had raised him to power. He found it necessary, therefore, to take further steps to guarantee the stability of his authority. The king was dying rapidly of consumption, and his sister Mary being heir to the throne, Northumberland could not hide from himself the probability that his own overthrow would follow her accession. He therefore took advantage of the king's strong religious prejudices to persuade him to make a will, excluding Mary and Elizabeth from the succession to the throne on the ground of their illegitimacy, and nominating as his successor Lady Jane Grey, who was married to the duke's eldest son. The arbitrary urgency of Northumberland and the religious obstinacy of Edward prevailed over the strong objections of the judges, and letters patent being drawn out in accordance with the king's wishes, passed under the Great Seal, and were signed by the chief nobles, including, although only after repeated endeavours to alter Edward's determination, Cranmer, archbishop of Canterbury. Edward died July 4, 1553. There were some suspicions that his death had been hastened by Northumberland, but although his malady showed at last some symptoms of poisoning, it is now believed that these were caused by accidental administrations of over-doses of mineral medicine. The early age at which Edward VI. died makes it impossible to form a confident estimate of his character and abilities. The exceptional talent which he manifested in certain respects may have been due largely to the

precocity caused by disease. He was undoubtedly highly accomplished, but there is some reason for suspecting that he was defective in force of character, and that he was too much of a recluse to have become a successful ruler. His own writings show that he was fully aware of the abuses which had crept into the administration of affairs, and that he was conscientiously desirous that they should be remedied; but they leave it uncertain whether he had the practical sagacity to discern the true causes of these evils, and whether he had sufficient energy to remedy them even had he known the proper remedies.

The Writings of Edward VI. (including his Journal), edited with Historical Notes and a Biographical Memoir by John Gough Nichols, have been printed in two vols. by the Roxburgh Club (London, 1857). See also Hayward's Life of Edward VI. and Froude's History of England, vols. iv. and v.

EDWARD THE BLACK PRINCE (1330-1376), son of Edward III. of England, and of Philippa, was born at Woodstock, June 15, 1330. In 1337 he was created duke of Cornwall. He was appointed guardian of the kingdom during the king's absences in France in 1338, 1340, and 1342, and on his return in 1343 was created prince of Wales. In 1346 he accompanied his father's fourth expedition against France, when the division led by him bore the chief brunt in the battle of Crécy. In 1350 he shared with his father the glory of defeating the Spanish fleet at the battle of "L'Espagnols-sur-Mer." In 1355 he commanded the principal of the three armies raised by the English for the invasion of France, and landing at Bordeaux captured and plundered the chief of its southern towns and fortresses. In the year following he gained the great victory of Poitiers, and took King John prisoner; and returning to England in 1357, he entered London in triumphant procession, accompanied by his illustrious captive. During the pause of arms which followed the treaty of Breigny he was married to his cousin Joan, commonly called the Fair Maid of Kent, of whom he was the third husband. This event took place in 1361. Shortly after, he was created duke of Aquitaine, and he set sail for his new dominions in February 1363. Here his life was spent in comparative quietude until Pedro, the deposed monarch of Castile, sought his assistance to remount the Spanish throne. Trusting to Pedro's promises to defray the cost of the expedition, the Black Prince agreed to his request. He marched across the Pyrenees, defeated Don Henry with great slaughter at the battle of Navarrete, and two days afterwards, along with Don Pedro, entered Bourges in triumph. Don Pedro, however, speedily forgot the promise of payment which his distresses had induced him to make, and after the Black Prince had waited some months in vain for its fulfilment, he was compelled to return to his duchy, having lost four-fifths of his army by sickness alone. To defray his expenses he found it necessary to impose on Aquitaine a hearth tax, and the Gascon lords having complained to the king of France, he was summoned in 1369 to Paris to answer the complaint. He replied that he was willing and ready to come, but it would be with "helm on head, and with 60,000 men." War was consequently again declared between England and France. Two simultaneous invasions of English territory were planned by the French—the one under the duke of Anjou, the other under the duke of Berri. The latter laid siege to Limoges, which by the treachery of its bishop basely surrendered. Enraged almost to madness, the prince swore by the "soul of his father" that he would recover the city, and after a month's siege fulfilled his oath. Surprising the garrison by the springing of a mine, he carried the city by assault, and massacred without mercy every man, woman, and child found within its walls. This terrible act of cruelty, attributable, it is

only charitable to suppose, partly to the irritation of ill health, and possibly to chagrin arising from the presentiment that the English power in France was now on the wane, is the one blot on his fair fame. It closed also his military career, for he was compelled in 1371, by the advice of his physicians, to return to England. From this time his constitution was utterly broken, but he lingered on to witness the loss of his duchy to England, and also to originate the measures of the "Good Parliament," although his death prevented their completion. He died at Westminster, 8th June 1376. He was buried at Canterbury Cathedral, where his mailed effigy may still be seen.

EDWARDES, SIR HERBERT BENJAMIN (1819-1868), major-general in the East Indian army, one of the noblest names on the roll of the soldier statesmen of the British Indian empire, was born at Frodesley, in Shropshire, November 12, 1819. The family was of high standing. Sir Herbert's father was Benjamin Edwardes, rector of Frodesley, and his grandfather Sir John Edwardes, baronet, eighth holder of the title, which was conferred on one of his ancestors by Charles I. in 1644. After receiving his early education at a private school, he was sent to King's College, London, to complete his studies. Through the influence of his uncle, Sir Henry Edwardes, he was nominated in 1840 to a cadetship in the East India Company; and on his arrival in India, at the beginning of 1841, he was posted as ensign in the First Bengal Fusiliers. He remained with this regiment about five years, and during this period gave proof of that "great capacity for taking pains" which is the characteristic of genius. He mastered the lessons of his profession, obtained a good knowledge of Hindustani, Hindi, and Persian, and attracted attention by the political and literary ability displayed in a series of letters which appeared in the *Delhi Gazette*. In November 1845, on the breaking out of the first Sikh war, Edwardes was appointed aide-de-camp to Sir Hugh (afterwards Viscount) Gough, then commander-in-chief in India. On the 18th of the following month he served at the battle of Moodkee, and was severely wounded. He soon recovered sufficiently to resume his duties, and fought by the side of his chief at the decisive battle of Sohraon (February 10, 1846), which closed the war. He was soon afterwards appointed third assistant to the commissioners of the Trans-Sutlej Territory; and in January 1847 was named first assistant to Sir Henry Lawrence, the resident at Lahore. Lawrence became the great exemplar of the young hero, who looked up to him with the affectionate reverence of a disciple and a son, and in later years was accustomed to attribute to the influence of this "father of his public life" whatever of great or good he had himself achieved. He took part with Lawrence in the suppression of a religious disturbance at Lahore in the spring of 1846, and soon afterwards assisted him in reducing, by a rapid movement to Junnood, the conspirator Imaum-nd-din. In the following year a more difficult task was assigned him,—the conduct of an expedition to Bannoo, a tributary Afghan district, in which the people would not tolerate the presence of a collector, and the revenue had consequently fallen into arrear. By his rare tact and fertility of resource, Edwardes succeeding in completely conquering the wild tribes of the valley without firing a shot, a victory which he afterwards looked back upon with more satisfaction than upon other victories which brought him more renown. His fiscal arrangements were such as to obviate all difficulty of collection for the future. In the

spring of 1848, in consequence of the murder of Mr Vans Agnew and Lieutenant Anderson at Mooltan, by order of the Dewan Moolraj, and of the raising of the standard of revolt by the latter, Lieutenant Edwardes was authorized to march against him. He set out immediately with a small force, occupied Lena on the left bank of the Indus, was joined by Colonel Cortlandt, and, although he could not attack Mooltan, held the enemy at bay and gave a check at the critical moment to their projects. He won a great victory over a greatly superior Sikh force at Kineyrec (June 18), and received in acknowledgment of his services the local rank of major. In the course of the operations which followed near Mooltan, Edwardes lost his right hand, by the explosion of a pistol in his belt. On the arrival of a large force under General Whish the siege of Mooltan was formed, but was suspended for several months in consequence of the desertion of Shere Singh with his army and artillery. Edwardes distinguished himself by the part he took in the final operations, begun in December, which ended with the capture of the city, January 4, 1849. For his services he received the thanks of both houses of parliament, was promoted major by brevet, and created C.B. by special statute of the order. The directors of the East India Company conferred on him a gold medal and a good service pension of £100 per annum. After the conclusion of peace Major Edwardes came to England for the benefit of his health, married during his stay there, and wrote and published his fascinating account of the scenes in which he had been engaged, under the title of *A Year on the Punjab Frontier in 1848-1849*. His countrymen gave him a fitting welcome, and the university of Oxford conferred on him the degree of D.C.L. In 1851 he returned to India and resumed his civil duties in the Punjab under Sir Henry Lawrence. In November 1853, he was entrusted with the responsible post of commissioner of the Peshawar frontier, and this he held when the Mutiny or Sepoy War of 1857 broke out. It was a position of enormous difficulty, and momentous consequences were involved in the way the crisis might be met. Edwardes rose to the height of the occasion. He saw as if by inspiration the facts and the need, and by the prompt measures which he adopted he rendered a service of incalculable importance, by effecting a reconciliation with Afghanistan, and securing the neutrality of the Amir and the tribes during the war. So effective was his procedure for the safety of the frontier that he was able to raise a large force in the Punjab and send it to co-operate in the siege and capture of Delhi. In 1859 Edwardes once more came to England, his health so greatly impaired by the continual strain of arduous work that it was doubtful whether he could ever return to India. During his stay he was created K.C.B., with the rank of brevet colonel; and the degree of LL.D. was conferred upon him by the university of Cambridge. Early in 1862 he again sailed for India, and was appointed commissioner of Ambala and agent for the Cis-Sutlej states. He had been offered the governorship of the Punjab, but on the ground of failing health had declined it. In February 1865, he was compelled finally to resign his post and return to England. A second good service pension was at once conferred on him; in May 1866, he was created K.C. of the Star of India, and early in 1868 was promoted major-general in the East Indian army. It was known that he had been for some time engaged on a life of Sir Henry Lawrence, and high expectations were formed of the work, but he did not live to complete it. He died in London, December 23, 1868. Sir Herbert Edwardes, great in council and great in war, was singularly beloved by personal friends, and was generous and unselfish to a high degree. He was also a man of deep religious convictions.

and naturally desired and hoped for the evangelization of India. But his zeal was under the restraint of knowledge, and he knew how to reconcile private aspiration with public duty. Like Sir John Lawrence, he advocated toleration for the native religious systems, and at the same time deprecated Government support of them in any way. "India," says a writer in the *Pall Mall Gazette*, "has produced many great men, some of whom have done more for their country, but there were few upon whom the stamp of genius was more visibly impressed than upon Herbert Edwards." The life of Sir Henry Lawrence was completed by Mr Herman Merivale, and was published in 1873.

EDWARDS, BRYAN (1743–1800), the well-known historian of the West Indies, was born at Westbury, in Wiltshire, on the 21st of May 1743. His father died in 1756, and his education and maintenance were undertaken by his maternal uncle, Zachary Bayly, a wealthy West Indian merchant. He had been placed by his father at the school of a dissenting clergyman in Bath, where he received a careful training in English composition, his uncle's agent, however, removed him to a French boarding school, on discovering that he had received no instruction in classics. Edwards went out to Jamaica to join his uncle, in whom he seems to have found everything he could desire,—the most enlightened mind, the sweetest temper, and the most generous disposition. To this was added a truly paternal regard for himself, which was returned with all the warmth of filial affection. His uncle, finding him possessed of literary talents, but deficient in classical acquirements, engaged a Mr Teale, a clergyman and formerly master of a free grammar-school, as resident tutor for him. The relationship proved a very agreeable one to both teacher and pupil, though the training imparted was somewhat fragmentary. A large proportion of their time was spent in tasting the beauties of Dryden and Pope, and in laughing at the comic sallies of Molière. Edwards, upon the whole, acquired during this period small Latin and less Greek; but he continued to practise composition both in prose and verse, and the two companions sent occasional pieces to the colonial newspapers. On the death of his uncle Edwards succeeded to his property, and, in 1773, he became heir to the much larger estate of Mr Hume, also of Jamaica. In 1784 he published *Thoughts on the Proceedings of Government respecting the Trade of the West Indian Islands with the United States of America*. This was followed by a speech delivered at a free conference between the Council and Assembly at Jamaica, held November 25, 1789, on the subject of Wilberforce's propositions concerning the slave trade. It was in 1793, however, that he published his great work, on which he had been many years engaged, entitled *History, Civil and Commercial, of the British Colonies in the West Indies*, 2 vols 4to. On the question of slavery and the slave trade he naturally took the planter's view, but he expressed himself with moderation and candour. In 1796 he published, in one volume quarto, a *History of St Domingo*, which had then excited a deep interest, on account of the insurrection of the slaves, and the consequent establishment of an independent negro government. In 1801 a new edition of both these works was published, in three vols. 8vo, under the general title of *History of the West Indies*. A fifth edition issued from the press in the year 1819. When Mungo Park returned from his celebrated journey in Africa, Edwards, from his oral information, drew up a report of it, which was submitted to the African Society, and published in their *Transactions*. Park afterwards incorporated the greater part of this into the general narrative of his *Travels*, in preparing which he availed himself much of the assistance and suggestions of Edwards. After a lengthened residence in Jamaica Edwards returned to England, and in 1796

became M.P. for the borough of Grampound, which he continued to represent till his death, July 15, 1800. He left a short narrative of his life, which was prefixed to the edition of his history published in 1801.

EDWARDS, GEORGE (1693–1773), a celebrated antiquarian and ornithologist, was born at Stratford, in Essex, on the 3d April 1693. He was originally apprenticed to a tradesman in Fenchurch Street, London; but obtaining by accident access to a number of books on natural history, painting, astronomy, and antiquities, he lost his inclination for mercantile pursuits, and acquired a desire for foreign travel. In 1716 he visited the principal towns in Holland, and two years afterwards travelled in Norway and Sweden. In 1719 he went to Paris for the purpose of studying its natural history collections, and during his stay in France he made two journeys of a hundred miles each, the first to Châlons in Champagne, and the second on foot to Orleans and Blois. On his arrival in England he closely pursued his favourite study of natural history, applying himself to drawing and colouring such animals as fell under his notice. Birds first engaged his particular attention, and having purchased some of the best pictures of them, he made a few drawings of his own, which were admired by the curious, who encouraged the young naturalist by paying a good price for his early labours. In 1731 he made an excursion to Holland and Brabant, where he collected several scarce books and prints, and had an opportunity of examining the original pictures of several great masters, at Antwerp, Brussels, Utrecht, and other cities. In December 1733, by the recommendation of Sir Hans Sloane, the president of the college of physicians, he was chosen librarian to that body, and had apartments assigned him in the college. Here he had the opportunity of a constant recourse to a valuable library filled with scarce and curious books on the subject of natural history, which he so assiduously studied. By degrees he became one of the most eminent ornithologists in his own or any other country. He published the first volume of the *History of Birds* in 1743, a second volume in 1747, a third in 1750, and a fourth in 1751. In 1758 he continued his labours under a new title, that of *Gleanings of Natural History*. A second volume of the gleanings was published in 1760, and a third in 1764. The two works contain engravings and descriptions of more than six hundred subjects in natural history not before described or delineated. He likewise added a general index in French and English, which was afterwards perfected with the Linnæan names by Linnæus himself, who frequently honoured him with his friendship and correspondence. In 1750 he received the gold medal of the Royal Society, given annually on St Andrew's day to the author of any new discovery in art or nature. He was, a few years afterwards, elected fellow of the Royal Society, and of the Society of Antiquaries, London, and also a member of many of the academies of sciences and learning in different parts of Europe. After the publication of his last work, having arrived at his seventieth year, and finding his sight beginning to fail, and his hand losing its wonted steadiness, he retired from public employment to a little house which he had purchased at Plaistow. The conversation of a few select friends, and the perusal of a few select books, were the amusement of the evening of his life; and now and then he made an excursion to some of the principal cities in England, particularly to Bristol, Bath, Exeter, and Norwich. His general health began to fail some years before his death, which took place on the July 23, 1773.

EDWARDS, JONATHAN (1703–1758), the most distinguished metaphysician and divine of America, was the son of the Rev. Timothy Edwards, and of Esther, daughter of the Rev. Solomon Stoddard, of Northampton, and was born at

East Windsor, Connecticut, October 5, 1703. He was the only son in a family of eleven children, of whom four were older than himself. Even in his very early years the religious instruction communicated to him by his parents seems to have engaged a large share of his interest, and to have exercised a strong influence on his character. In a statement of his religious views in youth, he says, "I had a variety of concerns and exercises about my soul from my childhood," and also, "from my childhood up my mind had been full of objections against the doctrine of God's sovereignty." In his eighth or ninth year he experienced, he tells us, "two remarkable seasons of awakening;" but these objections against the doctrine of God's sovereignty continued to trouble him more or less until about his 17th year, "when," he says, "I seemed to be convinced and fully satisfied as to this sovereignty of God, and his justice in thus eternally disposing of men, according to his sovereign pleasure, but never could give an account how or by what means I was convinced, nor in the least imagined at the time, nor a long time after, that there was any extraordinary influence of God's Spirit in it." Until he entered college his education was conducted by his father, with the occasional assistance of his elder sisters. At the age of six he began the study of Latin, and in that language, as well as in Greek and Hebrew, he attained to considerable proficiency. In September 1716 he entered Yale College. He took his B.A. degree in 1720, but with a view to preparation for the ministry he continued his residence at college for two additional years. In 1718 he read Locke on the *Human Understanding*, and it was from its perusal that his intense passion for abstract thought was first kindled. He declared that it had afforded him "far higher pleasure than the most greedy miser finds when gathering up handfuls of silver and gold from some newly discovered treasure." He received licence to preach in 1722, and in August of that year, on the invitation of a number of ministers in New England, he went to preach to the Presbyterians in New York, where he continued eight months. He was invited by the congregation to continue with them permanently, but on account of doubts as to his future usefulness in that particular sphere, he declined their invitation, and returned to his father's house at East Windsor. Here he prosecuted his studies in theology and metaphysics till June 1724, when he was appointed tutor in Yale College. About this time he completed the series of seventy resolutions begun during his preparation for the ministry, and designed to "regulate his own heart and life." No. 11 of these may be mentioned as specially characteristic:—"Resolved, when I think of any theorem in divinity to be solved, immediately to do what I can towards solving it, if circumstances do not hinder." He resigned his tutorship in September 1726, on receiving an invitation from Northampton to become colleague and successor to his grandfather, the Rev. Samuel Stoddard, and in February 1727 he was ordained to that office. In the following July he was married to Sarah, daughter of the Rev. James Pierrepont, of New Haven. He continued at Northampton till June 22, 1750, when, on account of a dispute that had arisen from an attempt on his part to prohibit some of the younger members of his congregation from perusing certain books, which in his opinion were obscene, he found himself compelled to resign his charge. On learning of his resignation some of his friends in Scotland advised him to settle in that country, and he was also invited to a church in Virginia, but he accepted in preference to either invitation the proposals made to him by the "Society in London for Propagating the Gospel in New England," that he should become missionary to the Housatonnuck Indians, who were settled at Stockbridge, Berkshire Co., Massachusetts. The nature of his work now left him in possession of considerable

leisure, of which he made use to such advantage that, within the six years of his residence at Stockbridge, he completed four of his principal treatises, including that on the *Freedom of the Will*, which was published in 1754. On account of the fame which this work acquired for him he was in 1757 called to succeed President Burr of Princeton College, New Jersey. He was installed February 16, 1758, but was scarcely spared to enter upon the performance of his duties. On account of the prevalence of small-pox in the neighbourhood, he submitted to inoculation and the disease taking an unfavourable turn, he died on the 28th March. Edwards says of himself that he possessed "a constitution in many respects peculiarly unhappy, attended with flaccid solids, rapid, sizy, and scarce fluids, and a low tide of spirits, often occasioning a kind of childish weakness and contemptibleness of speech, presence, and demeanour." Notwithstanding this unhappy constitution, he was throughout life a laborious student, often prosecuting, pen in hand, his arduous metaphysical researches for thirteen hours daily. As an orator he sometimes held not only the feelings but the intellects of his hearers completely under his sway. The extraordinary influence which he thus exercised was not due to any personal advantages, for even when his oratory was most effective the "contemptibleness of his speech and demeanour" still remained, although it was no longer felt by his hearers, nor to any special excellences of style, for though his language conveyed his meaning without ambiguity, it did so not only without any of that peculiar felicity of arrangement which is usually one of the chief elements of successful oratory, but in a bald, even in a lumbering and awkward, manner. His eloquence was simply intense moral earnestness, expressed in the form of what, in more senses than one, might be called "merciless logic."

His writings present a very remarkable conjunction of apparently contradictory qualities, a conjunction attributable partly to a peculiar combination of natural mental characteristics, and partly to a habit of solitariness which rendered him almost completely ignorant of the dominant tendencies of contemporary thought, and placed him almost beyond the reach of any external influences fitted to aid him in freeing himself from the shackles of past systems. The outstanding features of his character were undoubtedly his sense of reverence and his passion for ratiocination. In one respect these two opposite characteristics combined to produce a harmonious result, namely, to impress him with an almost overwhelming conviction of the claims of duty. His awe of the Supreme Power was in one aspect of such a nature as to seem consistent only with the grossest superstition, but from the very fact that it was the awe of an intellect, within the sphere of logic, so keen and penetrating, it was necessarily a moral awe, an awe which intensified that sense of duty whose requirements his logical faculty revealed with a distinctness which admitted of no fallacy or evasion. It was his overwhelming conviction of duty which gave to his system, theological, moral, and metaphysical, what unity it possesses. That unity is, however, nothing more than seeming; the positive and negative elements are held apart in different spheres; if they were brought into contact the necessary result would be an utterly destructive explosion. The basis of his whole system is the "sovereignty of God;" and of his conviction of God's "sovereignty" he tells us that of how or by what means he arrived at it he could give no account. This mysterious and unaccountable conviction he, however, endeavours to justify by a protracted logical process, without being at all conscious of any incongruity between means and end. This unconsciousness is due to the fact that the strength of his original conviction prevented him from discerning the real difficulties he had to surmount. We have

thus presented to us the spectacle of a mystic endeavouring to expound his belief by a mere process of reasoning, almost mathematical in its cold and definite precision and in its rigour. It is quite possible that his strong prepossessions would in any case have prevented him from estimating at their proper importance the new problems that were beginning to appear on the horizon of contemporary thought, but, so far from having given these problems the attention necessary in order to understand them, he was scarcely aware of their existence. The impulse he received from Locke's *Essay on the Human Understanding* did not lead him to seek full acquaintance with the whole circle of the philosophical speculation of his time,—partly no doubt because his circumstances prevented him from doing so, but partly also because he had a strong bias towards the pursuit of solitary trains of thought. In his essay on the *Freedom of the Will* he confesses having never read Hobbes; and although he mentions in a letter having read one of Hume's works, this would appear to have been subsequent to the publication of the essay on the *Freedom of the Will*, and its perusal does not seem to have impressed him with any idea of its author's exceptional metaphysical ability, for he merely says of it and of some other books, "I am glad of an opportunity to read such corrupt books, especially when written by men of considerable genius, that I may have an idea of the notions which prevail in our country." He was scarcely conscious of the presence of the new influence which was then stirring the stagnant waters of speculation; but it certainly influenced him unconsciously, and compelled him to check his vague unrest by more steadfastly clinging to his old convictions. He succeeded in doing so, but not without the exercise of constant watchfulness, for, apart from any immediate external influence, his strong and eager logical faculty seems often as if bent on carrying him beyond the bounds of traditional opinion, and requires frequently to be pulled up with a certain measure of abruptness.

The theological system of Edwards emphasized all the sterner features of Calvinism and revealed them in strong relief. Calvinism in its original form was founded on extreme statements regarding "God's sovereignty" and "man's depravity by nature," but the inferences implied in these statements are set forth by Edwards in their terrible and repulsive aspects with a thoroughness and a logical completeness not previously attempted. The argument he employs to establish his propositions is unanswerable as against the Libertarians of his time, for he shows conclusively that their plight is, if anything, rather worse than his own, but when he seeks to go beyond this very circumscribed sphere he involves himself in a labyrinth of scholastic quibbling, where all that seems to present itself is only a choice of two evils,—either to remain for ever utterly bewildered by the contradictory paths which open up before him, or by selecting one of them to wander irrevocably beyond the bounds of what he recognized as orthodox. We have an example of this when he endeavours to prove that though men are born utterly depraved, God is not the author of their depravity. His theory is that Adam was originally possessed of two principles,—one which may be called *natural*, being the mere principles of human nature, or as it is called in Scripture the *flesh*, and another called the *supernatural* principle, or as in Scripture the *divine nature*. When Adam ate of the tree of forbidden fruit the divine nature was withdrawn from him, and thus his nature became corrupt without God infusing any evil thing into it. "So," says Edwards, "does the nature of his posterity; they come into the world mere flesh, and entirely under the government of natural and inferior principles." Here it will be seen, not only that Edwards appears to very little advantage as a reasoner, but that he is in imminent peril of overthrowing the central position of his own system, for, first, if to represent sin as a merely negative quality in any degree solves the difficulty of God being its author, it does so at the expense of denying to it a real existence, and secondly, to represent men as born into the world "mere flesh" entirely destroys the distinction, so essential to Edwards's system, between "moral and natural inability." He soon, however, escapes back to his old position although not by the way he set out. "If any," he says, "should object to this that, if the want of original righteousness be thus according to an established course of nature, then why are not principles of holiness, when restored by divine grace, also com-

municated to posterity, I answer, the divine law and establishments of the Author of nature are precisely settled by Him as He pleaseth, and limited by His wisdom.

The moral theory of Edwards is but a corollary from his theological system. Virtue he places in love or benevolence towards being in general, or more accurately in a "disposition to benevolence towards being in general," for he does not mean to affirm that "every virtuous act must have universal existence for its direct and immediate object," but merely that "no affections towards particular persons or beings are of the nature of true virtue, but such as arise from a generally benevolent temper." He shows that this love cannot be primarily a "love of complacency," that is, a love having any regard to excellence in the object, for that "would be going in a circle, and the same as saying that virtue consists in love to virtue," and that it cannot consist in "gratitude, or one being benevolent to another for his benevolence to him," because "this implies the same inconsistency;" consequently that "the first object of a virtuous benevolence is being simply considered, and, if being simply considered, then being in general." There is, however, "a second object of a virtuous propensity of heart, namely, benevolent being, for one that loves being in general will necessarily value good-will to being in general." True virtue must, therefore, chiefly consist in love to God, for "he that has true virtue, consisting in benevolence to being in general, and in benevolence to virtuous being, must necessarily have a supreme love to God both of benevolence and complacency." This theory he applies to support the theological dogma that no one whose virtuous acts are not the result of real conscious love to a personal God can possess any true righteousness, or be in any other moral condition than that of utter depravity. As to the merits of the theory in itself, these are not helped by the form in which it is stated. Being in general, being without any qualities, is too abstract a thing to be the primary cause of love. The feeling which Edwards refers to is not love, but awe or reverence, and, moreover, necessarily a blind awe. Properly stated therefore, true virtue, according to him, would consist in a blind awe of being in general, and a love of complacency to those who possess a blind awe of being in general—only this would be inconsistent with his definition of virtue as existing in God. In reality, as he makes virtue merely the second object of love, his theory becomes identical with that utilitarian theory with which the names of Hume, Bentham, and Mill are chiefly associated; but it is utilitarianism necessarily expressed in very awkward terms, because these are hampered by its derivation from certain theological principles, and its necessary connection with a theological belief. Unlike Hume and Mill, he deduces his theory primarily from certain scholastic propositions regarding God's purpose in the creation of the world. He accepts the Scripture statement that God makes himself his own chief end, and he endeavours by scholastic reasoning to show the "reasonableness" of his doing so. He is, however, unable to proceed a step in his argument without committing himself to such pantheistic statements as that "God's existence, being infinite, must be equivalent to universal existence," and that "the eternal and infinite Being is in effect being in general, and comprehends universal existence." He is, therefore, obliged to confess that "there is a degree of indistinctness and obscurity in the close consideration of such subjects," and to fall back "on revelation as the surest guide in these matters;" although affirming at the same time that, in his endeavours "to discover what the voice of reason is so far as it can go," he has been successful in "obviating cavils insisted on by many."

The fame of Edwards is associated chiefly with his treatise on *The Freedom of the Human Will*. The will is defined by him as that by which the "mind chooses anything." By "determining the will" he means "causing that the act of the will or choice should be thus and not otherwise." And, "with respect to the inquiry, What determines the will?" he answers, "It is that motive which as it stands in the view of the mind is the strongest." Liberty, according to him, belongs not to the will itself, but to the person, and the liberty which any one possesses is merely liberty to act as he wills. Any other kind of liberty, he affirms, implies three suppositions—(1) "A self-determining power in the will," (2) "Indifference,—that previous to the act of volition the mind is in a state of equilibrium;" and (3) "Contingence,—that events are not necessarily connected with their causes." These suppositions, as involving in different forms denials of the law of causality, are severally shown to be absurd. That Edwards demonstrates the position of his opponents to be utterly untenable must without the least qualification be admitted; but he is unconsciously equally successful in overthrowing his own theological position. Accordingly Edwards's theory of the will, like his ethical theory, is now held only by those who, in regard to the supreme power, are agnostics. His theory differs in no respect from that of John Stuart Mill, except that his statement of the law of causality is a little confused, and that he gives a different account of the origin of our knowledge of causality. He so far anticipated Hume as to recognize that by cause is often meant "any antecedent with which a consequent event is so connected that it truly belongs to the reason why the

proposition which affirms that event is true, whether it has and positive influence in producing it or not." There is, of course, some confusion here, as the word "reason" is, in the position in which it stands, ambiguous, showing that Edwards never properly grasped the distinction between causality and mere sequence, and further differing from Hume in recognizing that there are causes which have a positive influence in producing their effects, his statements are rendered additionally perplexing by his unconsciously making use of either signification of the word cause, according to the exigencies of his argument. Thus he makes our knowledge not only of the law of positive causality but of mere sequence to depend not on experience but on a primary intuition "implanted by God in the minds of all mankind," which is virtually a contradiction in terms. There is also the further difficulty as to how, consistently with his theory in regard to the will, he can hold any other doctrine regarding causality than that it is that mere sequence which experience enables us to believe in; for it seems impossible that we can have a primary intuition of causality unless from the consciousness of our own casual energy.

That part of Edwards's argument in which he most decidedly fails is his endeavour to reconcile his theory of the will with his own views in regard to moral agency, and more particularly in regard to the nature of reward and punishment. John Stuart Mill admits that, on his own theory, the only ends that can justify punishment are the benefit of the offender himself and the protection of others, and the only "feeling of accountability" he contends for is that "caused by the experience of punishment." It has been disputed whether even the kind of punishment contended for by Mill is on his theory justifiable, but he has endeavoured to obviate objections to it by distinguishing between what he calls "modified fatalism" and what he calls the "true doctrine of causation." The distinction is similar to that drawn by Edwards between "moral" and "natural" necessity. It may be questioned whether Mill's doctrine of causality leaves room for this distinction, but undoubtedly Edwards's doctrine does not, for by tracing our knowledge of causality not to experience but to a primitive intuition, he becomes not merely a "determinist," but a "necessitarian." Whether the doctrine of the will held by Edwards, Hume, and Mill be the correct one, or whether the true solution of the problem or its true statement is to be found in some form of the transcendental philosophy which received its great impulse from Kant, it is not our province to inquire; but there need be no hesitation in affirming both that Edwards is successful in showing that the doctrine of the freedom of the will must be stated in different terms and justified by different methods than those employed up to his time, and that, on account of his attempting to build on principles so widely removed from each other as to be utterly irreconcilable, his own well-planned structure, notwithstanding extraordinary applications of architectural skill, inevitably collapses.

The collected works of Jonathan Edwards, including a large number of sermons, were first published at Worcester, Mass., 1809, in 8 vols. 8vo. Among various other editions afterwards published may be mentioned that by his relative Sereno E. Dwight, 1850, in 10 vols., containing a memoir by Dr Dwight. This edition, with an introductory essay by Henry Rogers, was published at London in 1840, in two vols. Edwards's principal treatises are — *Religious Affections* (1746); *Life of Brainerd* (1749); *Freedom of the Will* (1754); *God's Last End in the Creation of the World* (1755); *Original Sin* (1758); the uncompleted *History of Redemption* (1777); and *Nature of Virtue* (1789). There is an interesting sketch of Edwards's life, character, and opinions in Leslie Stephen's *Hours in a Library* (2d series, 1876). (T F H)

EDWARDS, RICHARD (1523 ?–1566 ?), a musician and writer of interludes, was born in Somersetshire, studied at Corpus Christi College, Oxford, took his master of arts degree in 1547, entered at Lincoln's Inn, and was appointed in 1561 a gentleman of the royal chapel and master of the singing boys. He probably died about the end of 1565, as his epitaph was written by Turberville in the following year. A "tragedy" from his pen—possibly, in spite of the designation, the comedy of *Damon and Pythias*—was acted before Queen Elizabeth at Christmas 1564; and on September 3, 1566, the same honour was accorded to his *Palamon and Arcite*. The latter play was never printed, and like most of the author's productions is now lost, but the former, entered at Stationers' Hall in 1567–8, appeared in 1571 with the title of "The excellent Comedie of two the moste faithfullst freendes, Damon and Pythias," was reprinted in 1582, and may be found in Dodsley's *Old Plays*, vol. i., and *Ancient British Drama*, vol. i. It is written in rhymed lines of rude construction, varying in length and neglecting the *cæsura*, and, according to A. W. Ward, it is "one of the clumsiest of our early plays, both in action and in language." Its principal subject is tragic, but it is interlarded with scenes of vulgar and witless farce. A

number of the author's shorter pieces are preserved in the *Paradise of Dainty Devices*, first published in 1575, and reprinted in the *British Bibliographer*, vol. iii.; the best known are the lines on May, the *Amantum Irae*, and the *Commendation of Music*, which has the honour of furnishing a stanza to *Romeo and Juliet*. The *Historie of Damocles and Dionise* is assigned to him in the 1578 edition of the *Paradise*. In his own day Edwards was held in the highest estimation. "He united," says Warton, "all those arts and accomplishments which minister to popular pleasantry; he was the first fiddler, the most fashionable sonneteer, the readiest rhymers, and the most facetious mimic of the court."

EDWIN, or EADWINE, king of Northumbria, was the son of Ælla, king of Deira, and was born about 586. At the death of Ælla, in 588, Ethelfrid, king of Bernicia, Ælla's brother-in-law, usurped the throne of Deira, and united the two kingdoms Deira and Bernicia, under the name of Northumbria. Edwin ultimately found shelter with Rædwald of East Anglia, who, in 617, defeated and slew Ethelfrid near the river Idle, and enabled Edwin to mount the Northumbrian throne. In 625 Edwin married Ethelburgha, daughter of Edbert, king of Kent. She had been converted to Christianity, and, at her desire, Paulinus, a Christian missionary, was allowed to enter Northumbria. Not long after Paulinus's arrival, Eumer, an envoy of the king of Wessex, made an attempt to assassinate Edwin, who was only saved by Lilla, one of his thanes, throwing himself between him and the assassin's weapon. The thane was killed, and the sword passing through his body inflicted also a dangerous wound on the king. The queen about the same time was seized by the pangs of childbirth, and was so alarmed on account of what had happened that she and her infant were for a time in imminent danger. Paulinus offered up prayers for their recovery, and Edwin was so much impressed by the seeming answer to the petition, that, though he did not at once adopt the Christian faith, he permitted the infant and twelve of his household to be baptized. He also declared to Paulinus that if he should succeed in overthrowing the West Saxons, against whom he had determined to make war, he would himself become a Christian, and receive the rite of baptism. After his victorious return he renounced his heathen gods, but it required all Paulinus's powers of persuasion to get him finally to adopt Christianity, and to give it his sanction as the religion of Northumbria. Ultimately, however, he convened a council of his nobles to ask their advice, and when they unanimously declared for the new religion, Coifi, the high priest, at once offered to destroy all the heathen places of worship throughout the land. This was done, and in 628 the Northumbrians flocked in crowds to be baptized by Paulinus. While the introduction of Christianity into Northumbria is the circumstance most worthy of mention in Edwin's reign, it was also remarkable in other respects. So strict was his administration of justice, that it was said that "a woman with her babe might walk scatheless from sea to sea in Edwin's day." He was also the first real Bretwalda, although Ælla, his father, first laid claim to the title. He compelled the submission of the West Saxons, conquered Angles and Man by his fleet, and received tribute from all the kingdoms south of the Humber, with the exception of Kent. To guard his northern dominion he erected the fortress of Edinburg or Edwin's burgh. In 633 Penda, king of Mercia, taking advantage of a reaction that was setting in in favour of the old paganism, determined to resist Edwin's authority, and combining with Cadwallader, king of the

Western Britons, defeated and slew him at the battle of Heathfield.

EDWY, EADWIG, or EDWIN, surnamed the Fair, an Anglo-Saxon king, was the son of Edmund I., and succeeded his uncle, Edred, on the throne in 955, being then from 16 to 18 years of age. His immediate rule was limited to Wessex, his younger brother Edgar reigning over Mercia with the title of sub-king. On account of the relation in which Edwy stood to Dunstan, abbot of Glastonbury, it is impossible, from the narratives that have been transmitted to us, to arrive at any certainty as to the interpretation to be given to his character, and to the main facts of his reign. It is said that on the day of his coronation he retired early from the banquet to the apartment of Elgiva, whom he undoubtedly recognized as his wife, but who, according to the monks, was related to him within the prohibited degrees; and that Dunstan, abbot of Glastonbury, enraged at the affront thus put upon the church, followed him, and not without violence dragged him back to the banqueting hall. Either for this particular manifestation of authority, or because the king was opposed to his policy of substituting monks for secular canons and was unable to restrain his domineering spirit, Dunstan was deprived of his offices and banished from the kingdom. The Mercians, however, revolted, and, proclaiming Edgar sole king, recalled Dunstan to their dominions. It is said also that Odo, archbishop of Canterbury, instigated a plot for separating Elgiva from Edwin, that she was sent to Ireland where her face was disfigured with hot searing irons, and that on her escape to England she was again seized and put to death by torture at Gloucester; but the monks affirm that the lady who was subjected to this treatment was not Elgiva, but her mother Ethelgiva, who was also the mistress of the king. Edwy died in 958.

ECKHOUT, GERBRAND VAN DEN (1621–1674), a painter, born at Amsterdam on the 19th of August 1621, entered early into the studio of Rembrandt. Though a companion pupil to F. Bol and Govaert Flinck, he was inferior to both in skill and in the extent of his practice; yet at an early period he assumed Rembrandt's manner with such success that his pictures were confounded with those of his master; and, even in our day, the Resurrection of the Daughter of Jairus, in the Berlin Museum, and the Presentation in the Temple, in the Gallery of Dresden, have been held to represent worthily the style of Rembrandt. As evidence of the fidelity of Eeckhout's imitation we may cite his Presentation in the Temple, at Berlin, which is executed after Rembrandt's print of 1630, and his Tobit with the Angel, at Brunswick, which is composed on the same background as Rembrandt's "Philosopher in Thought." Eeckhout not merely copies the subjects; he also takes the shapes, the figures, the Jewish dress, and the pictorial effects of his master. It is difficult to form an exact judgment of Eeckhout's qualities at the outset of his career. His earliest pieces are probably those in which he more faithfully reproduced Rembrandt's peculiarities. Exclusively his is a tinge of green in shadows marring the harmony of the work, a certain gaudiness of jarring tints, uniform surface, and a touch more quick than subtle. Besides the pictures already mentioned we should class amongst early productions on this account, the Woman taken in Adultery, in the Museum of Amsterdam; Anna presenting her Son to the High Priest, at the Louvre; the Epiphany, at Turin; and the Circumcision, at Cassel. Eeckhout matriculated early in the Guild of Amsterdam. A likeness of a lady at a dressing table with a string of beads, in possession of Mr Von Stummer, at Vienna, bears the date of 1643, and proves

that the master at this time possessed more imitative skill than genuine mastery over nature. As he grew older he succeeded best in portraits, a very fair example of which is the historian Dappers (1669), in the Städel collection. Eeckhout occasionally varied his style so as to recall in later years the "small masters" of the Dutch school. Waagen justly draws attention to his following of Terburg in Gambling Soldiers, at Stafford House, and a Soldiers' Merry-making, in the collection of the Marquis of Bute. A Sportsman with Hounds, probably executed in 1670, now in the Vander Hoo gallery, and a Group of Children with Goats (1671), in the Hermitage at St Petersburg, hardly exhibit a trace of the artist's first education. Amongst the best of Eeckhout's works Christ in the Temple (1662), at Munich, and the Haman and Mordecai of 1665, at Luton House, occupy a good place. Eeckhout died at Amsterdam on the 22nd of October, 1674.

EECLOO, the head town of a district in the province of East Flanders, Belgium, is situated near the Lieve, 11 miles N. W. of Ghent. It is a neat, clean, and well-built town, and possesses a variety of industries, among which are woollen and linen mills, manufactories of tobacco, chocolate, soap, and starch, breweries, and distilleries. It has also a considerable timber, grain, and cattle trade. Population in 1874, 10,200.

EEL, a name applied more or less generally to all the species of *Muraenidae*, a family of soft-finned apodal fishes, but more specially applicable to the species belonging to the sub-family *Anguillina*. The body throughout the family of eels is greatly elongated and of snake-like form. The ventral fins are wanting in all the species, while in certain forms, as the *Muraena*, the pectoral fins are also absent. The skin is thick and soft, and is covered over with a glutinous secretion which gives the eel its proverbial slipperiness. It is also sufficiently tough to enable it to be stripped entire from the body, and in some countries the skin is thus used as a bag or purse. Scales, disposed in groups, are present in the eels belonging to the genus *Anguilla*, but they are so buried beneath the outer layer or scarf skin as not to be apparent, while in such forms as the conger they are altogether wanting. The bronchial openings are small, and lead into a sac, from which another sac is given off. The gills are thus exposed but slightly to the drying influence of the atmosphere, and it is owing to this, and to the slimy condition of the skin, that eels can exist for a considerable time out of water. According to Dr Günther, the *Muraenidae* comprise 26 genera and 230 species, inhabiting the seas and fresh waters of temperate and tropical regions. Of these only the true eels, *Anguilla*, inhabit fresh water, although most of the latter are likewise marine.

Although abounding in almost every river, lake, and estuary in Europe, little was known until recently of the life-history of the fresh-water eels. With regard to their origin Aristotle believed that they sprang from the mud, Pliny that they took their rise from portions of the skin scraped off the parent body, while horse hairs and May-dew have both been regarded as fertile sources of eels. Until quite recently, they were regarded by naturalists as viviparous, a mistake which probably arose from the frequent presence of parasitic worms, supposed to be the young, in their bodies, and the absence of anything exactly resembling milt and roe as usually found. Like all other Teleostean fishes they are oviparous, the milt and roe occurring in the same position, but differing considerably in appearance from those elements in other fishes. The spawn of the eel is generally deposited in sand and mud at the mouths of rivers, and in harbours where the water is brackish. To reach these spawning grounds, eels migrate in autumn down the river channels, and at those times they

are taken in large numbers by various devices, such as the "eel-buck" of the Thames, a wooden framework supporting wicker baskets, the mouths of which are opposed to the stream, and which are so constructed that the fish when once inside is unable to extricate itself. When there are obstacles in the way of their getting to the sea, eels are known to deposit their spawn in the beds of fresh-water streams, but it is still doubtful whether this may not also occur in cases where the sea is quite accessible. Eels are peculiarly averse to cold, and the fact that the temperature of the brackish waters of estuaries is always higher than that of unmixed salt or fresh water is an additional reason for their seaward migration on the approach of winter. In performing this journey the darkest nights are chosen, the moonlight being sufficient to stay their progress. During the cold of winter they lose their appetite and become torpid, large numbers of them congregating together for the sake of the additional warmth thus obtained, and burying themselves to a depth of 12 to 16 inches in places where the receding tide leaves them dry. In such places they are taken in large numbers by means of eel-spears. In Somersetshire, according to Yarrell, "the people know how to find the holes in the banks of the rivers in which eels are laid up, by the hoar frost not lying over them as it does elsewhere, and dig them out in heaps." In spring, the migration of the young eels up the rivers takes place, the parents, according to some observers, performing a similar journey. This migration takes place from February to May, according to the temperature, and some idea of the vast numbers of young eels which annually pass up our rivers may be formed from the fact that 1800 of them, each about 3 inches long, have been observed to pass a given point on the Thames in a single minute. This monster procession of *elvers*, as these young eels are called, is known on the Thames as *el-fare*, and usually takes place about the beginning of May; and at these times, unfortunately, they are often caught in countless numbers in sieves, especially on the Severn, cartloads of them being sometimes seen for sale in the Exeter market. This upward migration, unlike that of autumn, is performed entirely by day, and it is carried through in spite of obstacles apparently insuperable to a fish. Eels have been known to climb up steep ascents, 20 feet above the water, showing great skill and ingenuity in availing themselves of whatever natural aids the locality might afford. Couch tells of a remarkable case in the neighbourhood of Bristol, where the elvers passed from one stream to another by means of a tree which stood between, and the branches of which dipped into the water of the lower. Ascending by these, the eels dropped from the branches on the opposite side into the upper stream. In some parts of Ireland the fishermen place haybunds on the rocky parts of the river-courses, in order to facilitate the upward progress of the eels. The most effectual obstacle, however, to their advance in either direction is found in a muddy or polluted state of the water; and old eels, to get rid of such nauseous conditions, have been known to leave the water and travel for considerable distances in search of purer surroundings. When confined also in ponds they often show their migratory instinct by leaving these in the night time, and attempting to make their way to the nearest river or to the sea.

Like most animals that pass the winter in a torpid condition, eels are exceedingly voracious during the summer months, occasionally eating vegetables, but generally preferring such animal food as young fishes, worms, and the larvæ of insects; they have also been known to devour much larger creatures, as water-hens, rats, and snakes. Although their food is thus very various, it is essential that it be fresh, eels at once rejecting whatever their keen sense of smell detects as tainted. Eels were held in great esteem

by the Greeks and Romans, and enormous prices were sometimes paid for them; by the Egyptians, on the other hand, they were held in abhorrence. Their snake-like appearance has had much to do with the prejudice entertained by many people against eels, and to this may be attributed the fact that in Scotland this valuable fish is almost wholly rejected as an article of food. Their value in this respect has, however, been recognized in England from very early times, the taste for eels having probably been acquired during the Roman occupation. The Venerable Bede states that England in his time was famous for its salmon and eel fisheries, and Ely is said to have got its name from the abundance of the eels in that fenny neighbourhood. Eels are very largely consumed in London, the greater proportion of these, numbering about 10 millions, being brought alive annually from Holland in walled boats. The greatest eel-breeding establishment in the world is that at Comacchio on the Adriatic, where an immense swamp, bounded and fed by two of the mouths of the river Po, 140 miles in circumference, has been utilized for this purpose. The industry is very ancient, having yielded in the 16th century an annual revenue to the Roman Pontiffs, in whose territory it was, of £12,000. The eels are cooked at Comacchio, and forwarded to the principal towns of Italy.

The best known and most widely distributed fresh-water species is the Sharp-nosed Eel (*Anguilla vulgaris*). It occurs, according to Dr Günther, in Europe to 64° 30' N. lat., in the Mediterranean region, and in North America, but neither in the Danube, nor in the Black and Caspian Seas. Like all other eels it is of comparatively slow growth, but often attains a large size, measuring sometimes 5 feet in length, and weighing in such cases from 20 to 30 lb. Few eels, however, weigh more than 6 lb. They are believed to be long-lived, one authentic instance being known of an eel which was at least 31 years old. The colour of the species is generally dark olive-green on the upper surface, becoming lighter on the sides, and white beneath; but the colour depends somewhat on the nature of the stream it inhabits, those obtained in pure water being known as silver eels from the lightness of their colour, while those found in muddy rivers are darker.

The Conger (*Conger vulgaris*) is the only British species of sea-eel. It differs from the true eels in having the upper jaw projecting beyond the lower, and in the entire absence of scales. It is abundant in all parts of the British coasts, especially on rocky ground, and attains a length of 10 feet, weighing in large examples over 100 lb. The conger is exceedingly voracious, feeding on other fishes, and not sparing even its own kind. Its jaws are strong and well-armed, and the capture of a large specimen is not unattended with danger to the fisherman. Its tail is exceedingly sensitive and prehensile, the conger being able with this organ to grasp the gunwale of the boat, and by a sudden contraction of the muscles to throw itself overboard, a smart blow on the tail, however, is sufficient to prevent the possibility of this occurrence. The conger is peculiarly sensitive to cold, and during severe frosts it is often taken floating helplessly on the surface of the sea. Mr F. Buckland states that in 1855 thousands of congers were found floating upon the water; they could progress readily in any direction on the surface, but could not descend, and consequently fell an easy prey to the boatmen. In this way, no less than 80 tons were captured. "The action of the frost," he says, "caused the air in their swimming bladders to expand so much that the ordinary muscles could not expel it at will." The chief conger fisheries are on the south and west coasts of England, but these are not nearly so productive now as they formerly were. The flesh is not held in much esteem.

The Electric Eel (*Gymnotus electricus*) belongs to a different family of apodal fishes (*Gymnotidae*). In it both caudal and dorsal fins are entirely wanting, and the anal fin is very long, forming a fringe from the throat to the extremity of the tail. It attains a length of 5 or 6 feet, and frequents the marshes of Brazil and the Guianas, where it is regarded with terror, owing to the formidable electrical apparatus with which it is provided, and which extends along each side of the lower portion of the tail. When this natural battery is discharged in a favourable position, it is sufficiently powerful to kill the largest animal; and, according to Humboldt, it has been found necessary to change the line of certain roads, owing to the number of horses that were annually killed in passing through the pools frequented by the gymnoti. These eels are eaten by the Indians, who, before attempting to capture them, seek to exhaust their electrical power by driving horses into the ponds. By repeated discharges upon these, they gradually expend this marvellous force; after which, being defenceless, they become timid, and approach the edge for shelter, when they fall an easy prey to the harpoon of the Indian. It is only after long rest and abundance of food, that this fish is able to resume the use of its subtle weapon. (J. G.)

EFFIGIES, MONUMENTAL.—In the course of the twelfth century the idea appears, for the first time, to have been carried into effect that the figure of a deceased personage should be represented by effigy upon his monumental memorial. These earliest attempts at commemorative portraiture were executed in low relief upon coffin-lids of stone or purbeck marble, some portions of the designs for the most part being executed by means of incised lines, cut upon the raised figure. Gradually, with the increased size and the greater architectural dignity of monumental structures, effigies attained to a high rank as works of art, so that before the close of the 13th century, very noble examples of figures of this order are found to have been executed in full relief; and, about the same period, similar figures also began to be engraved, either upon monumental slabs of stone or marble, or upon plates of metal, which were affixed to the surfaces of slabs that were laid in the pavements of churches. Engraven plates of this class, known as "Brasses," continued in favour until the era of the Reformation, and in our own times their use has been revived. It seems probable that the introduction and the prevalence of flat engraven memorials, in place of commemorative effigies in relief, were due, in the first instance, to the inconvenience and obstruction resulting from increasing numbers of raised stones on the pavement of churches; while the comparatively small cost of engraven plates, their high artistic capabilities, and their durability combined to secure for them the popularity they unquestionably enjoyed. It will be kept in remembrance that, if considerably less numerous than contemporary incised slabs and engraven brasses, effigies sculptured in relief, and with some exceptions in full relief, continued for centuries to constitute the most important features in more than a few mediæval monuments. In the 13th century, it must be added, their origin being apparently derived from the endeavour to combine a monumental effigy with a monumental cross upon the same sepulchral stone, parts only of the human figure sometimes were represented, whether in sculpture or by incised lines, as the head or bust, and occasionally also the feet; in some of the early examples of this curious class the cross symbol is not introduced, and after a while half-length figures became common.

Except in very rare instances, that most important element which may be distinguished as genuine face-portraiture is not to be looked for, in even the finest sculptured effigies, earlier than about the middle of the 15th century. In works of the highest order of art, indeed, the memorials

of personages of the most exalted rank, from an early period in their existence effigies may be considered occasionally to have been portraits properly so called; and yet even in such works as these an approximately correct general resemblance but too frequently appears to have been all that was contemplated or desired. At the same time, from the first, in these monumental effigies we possess contemporary examples of vestments, costume,¹ armour, weapons, royal and knightly insignia, and other personal appointments and accessories, in all of which accurate fidelity has been certainly observed with scrupulous care and minute exactness. Thus, since the monumental effigies of England are second to none in artistic merit, while they have been preserved in far greater numbers, and generally in better condition than in other countries, we may claim to possess in unbroken continuity an unrivalled series of original personal representations of the successive generations of our predecessors, very many of them being, in the most significant acceptance of that term, veritable contemporaneous portraits.

Till recently esteemed to be simply objects of antiquarian curiosity, and at no distant period either altogether disregarded or too often subjected to injurious indignity, the monumental effigies of England still await the formation of a just estimate of their true character and their consequent worth in their capacity as authorities for face-portraiture. In the original contract for the construction of the monument at Warwick to Richard Beauchamp, the fifth earl, who died in the year 1432, it is provided that an effigy of the deceased noble should be executed in gilt bronze, with all possible care, by the most skilful and experienced artists of the time; and the details of the armour and the ornaments of the figure are specified with minute particularity and precision. It is remarkable, however, that the effigy itself is described only in the general and decidedly indefinite terms—"an image of a man armed." There is no provision that the effigy should even be "an image" of the earl; and much less is there a single word said as to its being such a "counterfeit presentment" of the features and person of the living man, as the contemporaries of Shakespeare had learned to expect in what they would accept as true portraiture. The effigy, almost as perfect as when it left the sculptor's hands, still bears witness, as well to the conscientious care with which the conditions of the contract were fulfilled, as to the eminent ability of the artists employed. So complete is the representation of the armour, that this effigy might be considered actually to have been equipped in the earl's own favourite suit of the finest Milan steel. The cast of the figure also evidently was studied from what the earl had been when in life, and the countenance is sufficiently marked and endowed with the unmistakable attributes of personal character. Possibly such a resemblance may have been the highest aim in the image-making of the period, somewhat before the middle of the 15th century. Three-quarters of a century later, a decided step further in advance towards the requirement of fidelity in true portraiture is shown to have been taken, when, in his will (1510 A.D.), Henry VII. spoke of the effigies of himself and of his late queen, Elizabeth of York, to be executed for their monument, as "an image of our figure and another of hers." The existing effigies in the Beauchamp chapel and in Henry VII.'s chapel, with the passages just quoted

¹ It is well-known that the costume of effigies, almost as a rule, represented what was actually worn by the remains of the person commemorated, when prepared for interment and when lying in state; and, in like manner, the aspect of the lifeless countenance, even if not designally reproduced by mediæval "image" makers, may long have exercised a powerful influence upon their ideas of consistent monumental portraiture.

from the will of the Tudor king and from the contract made by the executors of the Lancastrian earl, with remarkable significance illustrate the gradual development of the idea of true personal portraiture in monumental effigies, during the course of the 15th and at the commencement of the 16th century in England. A glance upwards naturally first rests on the royal effigies still preserved in this country, which commence in Worcester Cathedral with King John. This earliest example of a series of effigies of which the historical value has never yet been duly appreciated is rude as a work of art, and yet there is on it the impress of such individuality as demonstrates that the sculptor did his best to represent the king. Singularly fine as achievements of the art of the sculptor are the effigies of Henry III., Queen Alianore of Castile, and her ill-fated son Edward II., the two former in Westminster Abbey, the last in Gloucester Cathedral; and of their fidelity also as portraits no doubt can be entertained. In like manner, the effigies of Edward III. and his queen Philippa, and those of their grandson Richard II. and his first consort, Anne of Bohemia (all in Westminster), and of their other grandson, the Lancastrian Henry, whose greater might made his better right to Richard's throne, with his second consort, Joan of Navarre, at Canterbury—these all speak for themselves that they are true portraits. Next follow the effigies of Henry VII. and Elizabeth of York,—to be succeeded, and the royal series to be completed, by the effigies of Queen Elizabeth and the hapless Mary Stuart, all of them in Westminster Abbey. Very instructive would be a close comparison between the two last-named works and the painted portraits of the rival queens, especially in the case of Mary, whose pictures differ so remarkably from one another.

As the 15th century advanced, the rank of the personage represented and the character of the art that distinguishes any effigy will go far to determine its portrait qualities. Still later, when more exact face-portraiture had become a recognized element, sculptors must be supposed to have aimed at the production of such similitude as their art would enable them to give to their works; and accordingly, when we compare effigies with painted portraits of the same personages, we find that they corroborate one another. The prevalence of portraiture in the effigies of the 16th and 17th centuries, when their art generally underwent a palpable decline, by no means raises all works of this class, or indeed the majority of them, to the dignity of true portraits; on the contrary, in these effigies, as in those of earlier periods, it is the character of the art in each particular example that will go far to determine its merit, value, and authority as a portrait. In judging of these latter effigies, however, they must be estimated by the standard of art of their own era; and, as a general rule, the effigies that are the best as works of art in their own class are the best also and the most faithful in their portraiture. The earlier effigies, evidently produced in the great majority of instances without any express aim at exact portraiture, as we now employ that expression, have nevertheless strong claims upon our veneration. Often their sculpture is very noble; and even when they are rudest as works of art, there rarely fails to be a rough grandeur about them, as exhibited in the fine bold figure of Fair Rosamund's son, Earl William of the Long Sword, which reposes in such dignified serenity in his own cathedral at Salisbury. These effigies may not bring us closely face to face with the more remote generations of our ancestors, but they do place before us true images of what the men and women of those generations were.

Observant students of monumental effigies assuredly will not fail to appreciate the singular felicity with which the mediæval sculptors adjusted their compositions to the

recumbent position in which their "images" necessarily had to be placed. Equally worthy of regard is the manner in which not a few monumental effigies, and particularly those of comparatively early date, are found to have assumed an aspect neither living nor lifeless, and yet impressively life-like. The sound judgment also, and the good taste of these early sculptors, were signally exemplified in their excluding, almost without an exception, the more extravagant fashions in the costume of their era from their monumental sculpture, and introducing only the simpler but not less characteristic styles of dress and appointments. In all representations of monumental effigies, it must be kept in remembrance that they represent recumbent figures, and that the necessities of the effigies themselves have been adjusted to that position. With rare exceptions, when they appear resting on one side, these effigies lie on their backs, and as a general rule (except in the case of episcopal figures represented in the act of benediction, or of princes and warriors who sometimes hold a sceptre or a sword) their hands are uplifted and conjoined as in supplication. The crossed-legged attitude of numerous armed effigies of the era of mail-armour has been supposed to imply the personages so represented to have been crusaders or Knights of the Temple, but in either case the supposition is unfounded, and inconsistent with unquestionable facts. Much beautiful feeling is conveyed by figures of ministering angels being introduced as in the act of supporting and smoothing the pillows or cushions that are placed, in very many instances to give support to the heads of the recumbent effigies. The animals at the feet of these effigies, which frequently have an heraldic significance, enabled the sculptors, with equal propriety and effectiveness, to overcome one of the special difficulties inseparable from the recumbent position. In conclusion, it remains only to remark upon the masterly treatment of outline composition which so honourably distinguishes the earlier examples of the engraven effigies in monumental brasses. (C. B.)

EGBERT, or EGGBERT, king of the West Saxons, was born about 775, and laid claim to the throne in 786, but Brihtic was elected, and he was compelled to take refuge with Offa, king of Mercia. Although Offa refused to surrender him when requested by Brihtic, he declined to give him further protection. Egbert thereupon fled to France, and took up his residence at the court of Charlemagne; and it is doubtless to the training he received from that great general and statesman that the success of his reign in Wessex is in a large measure to be traced. When Brihtic was poisoned by his queen Edbrugha in 800, Egbert was recalled and ascended the West Saxon throne. From his reign may be dated the supremacy of the West Saxon kings in England. In 823 he defeated Beornwulf, king of Mercia, at Ellandun (near Wilton); and in the same year he united Kent, Essex, and Sussex to his crown, and compelled East Anglia to acknowledge him as its over-lord. In 827 he compelled the submission of Mercia, and leading an army into Northumbria received its submission without trial of battle. In 828 he conquered Wales, and thus the isle of Britain, with the exception of the Picts, the Scots, and the Strathclyde Welsh, acknowledged a West Saxon king as its over-lord. During the last period of his reign his kingdom was subjected to repeated attacks by the Danes. In 832 they ravaged Sheppey, and in 833 defeated Egbert at Carrum (thought by some to be Charmenth, in Devon), but in 835 he gained a great victory over a united force of Danes and Welsh at Hengestesdun, in Cornwall. He died in 836.

EGEDE, HANS (1686-1758), the first missionary of Greenland, was born in the vogtship of Senjen, in Norway, on the 31st January 1686. In his 22d year he became pastor at Waagen, in the bishopric of Drontheim, but the

study of the chronicles of the northmen having awakened in him the desire to visit the colony of northmen in Greenland, and to convert them to Christianity, he resigned his charge in 1717; and having, after great difficulty, obtained the sanction and help of the Danish Government in his enterprise, he set sail with three ships from Bergen on the 3d May 1721, accompanied by his wife and children. He landed on the west coast of Greenland on the 3d July, but found to his dismay that the northmen were entirely snperseded by the Esquimaux, in whom he had no particular interest, and whose language he would be able to master, if at all, only after years of study. But, though compelled to endure for some years great privations, and at one time to see the result of his labours almost annihilated by the ravages of small-pox, he remained resolutely at his post. He soon gained the affections of the people, and succeeded gradually in converting many of them to Christianity, and in establishing a considerable commerce with Denmark. Ill-health compelling him to return home in 1734, he was made principal of the seminary at Copenhagen, in which workers were trained for the Greenland mission; and from 1740 to 1747 he was superintendent of the mission. He died in 1758. He is the author of a book on the natural history of Greenland.

EGEDE, PAUL (1708-1789), son of the preceding, accompanied his father to Greenland, assisted him in his labours there, and acted as his successor from 1734 to 1740. On his return to Denmark he became professor of the theology in the mission seminary, and afterwards was superintendent of the Greenland mission. He published a Greenland-Danish-Latin Dictionary (1750), Greenland Grammar (1760), and Greenland Catechism (1756). In 1766 he completed the translation, begun by his father, of the New Testament into the Greenland tongue; and in 1787 he translated Thomas à Kempis. In 1789 he published a journal of his life in Greenland.

EGER, the chief town of a circle in the kingdom of Bohemia, is situated on the river Eger, and lies at the foot of one of the spurs of the Fichtelgebirge. It possesses an upper gymnasium and a real-school. In the townhouse, which at that time was the burgomaster's house, Wallenstein was murdered, 25th February 1634. His sword and writing table are exhibited in the town. Among the industries of Eger are the manufacture of cloth of various sorts, hats, and shoes. Population in 1869, 13,390.

Previous to the middle of the 12th century Eger and the Egergau formed an allodial possession of the counts of Vohburg; but they were added to the imperial domains on the marriage of Adelheid of Vohburg with Frederick I. After being repeatedly transferred from the one power to the other, according to the preponderance of Bohemia or the empire, the town and territory were finally incorporated with Bohemia in 1350, after the Bohemian king became the emperor Charles IV. Several imperial privileges, however, continued to be enjoyed by the town till 1849. It suffered severely during the Hussite war, during the Swedish invasion in 1631 and 1647, and in the War of the Austrian Succession in 1742. (See Gruber, *Die Kaysersburg zu Eger*, 1865, *Dravok, Aeltere Geschichte der Deutschen Reichstadt Eger und des Reichsgebietes Egerland*, 1874.)

EGG, the name given to the body formed in the female reproductive organs, which, when impregnated by the male element, gives origin to the young of animals. Although differing widely among themselves in form and structure, the eggs of all animals are found to consist of the same essential parts, viz., the germ cell, the yolk, and the yolk membrane, one chief difference between them consisting in the relative quantity of the yolk element present, thus apparently depending on the degree of development which the young attain before leaving the egg. Thus birds, which leave the shell in a highly developed state, have in their eggs a large quantity of yolk, besides the albumen or "white," which is added to the egg before it receives the outer calcareous covering and which, along with the yolk,

serves as a storehouse of food for the young chick during the process of incubation. In insects, on the other hand, which leave the egg in the immature condition of larvæ, the yolk is comparatively small, as it is also in mammals, whose eggs or ova are exceedingly minute, and which owe the high development they attain before birth to nourishment drawn directly from the parent. The majority of animals are *oviparous*,—that is, the eggs leave the body of the female and are hatched outside; a few are *ovo-viviparous*, the eggs being retained in the oviduct until the young are ready to leave; while mammals are *viviparous*, the young, after leaving the egg, attaining considerable development before birth, in the womb of the female. In oviparous animals the egg, within certain limits, is proportional in size to that of the adult form to which it gives origin; the larger the bird, for example, the larger, as a rule, is the egg. Thus, however, is not without exceptions; thus the egg of the guillemot is as large as that of the eagle, and ten times larger than that of the raven, although guillemot and raven are of nearly equal size.

Owing to the fluid nature of the contents of eggs, they are generally roundish in form, although in this respect they also offer considerable variety; thus the eggs of owls and of turtles are nearly spherical, those of ducks, crocodiles, and snakes oval, and those of most sea-fowl pear-shaped. The external covering is generally more or less smooth, as in the eggs of birds, but in the case of insects they exhibit the most varied markings, being covered with spines, tubercles, and pits, often symmetrically arranged. Considerable diversity also exists in the composition of the outer covering of the egg in oviparous animals; in snakes and lizards it consists of a parchment-like membrane not unlike the inner coating of a hen's egg, in birds, turtles, and crocodiles, there is a hard calcareous shell; in cartilaginous fishes, as sharks and rays, the egg in passing through the oviduct is imbedded in a four-sided horny case, from the corners of which tendrils are given off, by which the egg-capsule is moored to floating sea-weed. These, after the escape of the young fish, are often cast upon the shore, where they are familiarly known as "mermaids' purses." The external covering of the eggs of osseous fishes, as salmon and trout, is exceedingly tough and elastic, "rebounding," says Mr Frank Buckland, "from the floor like an india-rubber ball;" and this no doubt prevents them from being crushed in the gravelly beds of the running streams in which they are deposited. The eggs of frogs and toads are surrounded with a tough layer of albuminous substance, which expands in water into a transparent jelly. The eggs of the frog occur in great masses, piled together like miniature cannon balls, while those of the toad are connected together so as to resemble strings of beads. Among many molluscous animals the eggs are provided with an additional covering or *nidus*, consisting of a leathery pouch or cup, containing a large number of eggs. These capsules are either attached singly, by little stalks, to the rocks as in the common purpura (*Purpura lapillus*), or are extruded in a compound mass as in the whelk (*Buccinum undatum*). Those of the latter were named by Ellis "sea wash balls," from being used by the sailors instead of soap to wash their hands, and are common objects on the sea-shore. The greatest variety exists in the number of eggs produced by different animals, and even among forms allied to each other. Thus the common snail produces only from thirty to fifty eggs at a time, while other mollusks, as the whelk, deposit their spawn in tens of thousands. Among insects, the white ant is pre-eminently prolific, the queen being said to lay about sixty eggs in a minute, or upwards of 80,000 in a day, and as this probably continues for two years, it is estimated that the total number of her eggs amounts to fifty millions. Among mollusks the spawn or

spat, as it is called, in a single mature oyster, numbers 1,800,000. Among vertebrate animals, fish are the most prolific; the eggs or roe, as they are called, however, often fail to get fertilized by the *milt* of the male, and great quantities are also eaten by fishes and crustaceans, so that they do not increase so rapidly as might be supposed from the enormous number of their eggs. Thus in trout and salmon there are over a thousand eggs to every pound of their weight. According to Buckland (*Fish Culture*) a roach weighing $\frac{3}{4}$ lb was found to contain 480,480 eggs; a herring weighing $\frac{1}{2}$ lb, 19,840; a turbot of 8 lb weight, 385,200; and a cod of 20 lb, 4,872,000. Large quantities of the roe of the cod are used in France as food, and also as bait in the sardine fishery. The sturgeon is also exceedingly prolific, the eggs usually forming one-third of the entire weight of the creature; and in Russia these, in a prepared form known as *caviare*, are much esteemed as a table delicacy. The number of eggs in reptiles and birds is comparatively small, the common English snake depositing 16 to 20 of these in such situations as dung-hills, where they are left to be hatched by the heat generated in the decomposing mass. The crocodile buries about 25 eggs on the muddy banks of the rivers it frequents, and the turtle leaves the ocean to deposit from 150 to 200 on the shores of such oceanic islands as Ascension. The eggs of the crocodile are considered a luxury by the natives along the banks of the Nile, while those of the turtle are regarded as special delicacies by people of more refined tastes. Of birds, the most prolific in eggs are those domesticated forms which have been carefully selected by man for centuries, with a view to the improvement of their egg-laying capacity. The chief of these are the duck, which lays an egg daily during the season extending from March to July, and the barn-door fowl, which produces annually about 120 eggs. The rearing of the latter for egg-producing purposes has now become an important industry in France and Belgium, and in a customs' return just issued (July 1877) it is stated that eggs were imported into Britain last year to the extent of 753 millions, valued at £2,620,000. The number has increased 41 per cent. since 1872, and it is now nearly seven times what it was in 1856. Besides these, the eggs of the turkey, the guinea fowl, the partridge, and other gallinaceous birds are in great request as articles of food. The eggs of the guillemot are also occasionally offered for sale in our markets, while these and the eggs of other species of sea-fowl form an important article of food among the western islands and along the north-western sea-coast of Scotland. The largest eggs are those produced by the emu and the ostrich, a single ostrich egg weighing as much as three dozen eggs of the barn-door fowl. These are eaten in Africa both by the natives and by Europeans. From two to five female ostriches are said to deposit their eggs (10 in number) in one nest, and the natives by removing, during the absence of the female, a few of these at a time, taking care not to touch them with their fingers, but using sticks to prevent any taint of their presence being left behind, get them to continue depositing eggs for a considerable time to supply the place of those removed. The shells are used throughout Africa as drinking-cups. The egg of the moa, some specimens of which have been found buried in New Zealand, is much larger than that of the ostrich, measuring in one specimen 10 inches in length and 7 inches broad. A still larger egg has been found fossil in Madagascar, the produce of the extinct *aviornis*, and having a capacity equal to that of 148 eggs of the common fowl.

(J. GL.)

EGG, AUGUSTUS LROPOLD (1816–1863), a painter, was born on 2d May 1816, in Piccadilly, London, where his father carried on business as a gun-maker. He had some schooling at Bexley, and was not at first intended for the artistic profession; but, developing a faculty in this line, he entered in 1834 the drawing class of Mr Sass, and in 1835 the school of the Royal Academy. His first exhibited picture appeared in 1837 at the Suffolk Street Gallery. In 1838 he began exhibiting in the Academy, his subject being a Spanish Girl; altogether he sent twenty-seven works to this institution. In 1848 he became an associate, and in 1860 a full member, of the Academy. In 1857 he took a leading part in selecting and arranging the modern paintings in the Art-Treasures Exhibition in Manchester. His constitution being naturally frail, he went in 1853, with Dickens and Wilkie Collins, to Italy for a short trip, and in 1863 he visited Algeria. Here he benefited so far as his chronic lung-disease was concerned; but, riding out one day exposed to a cold wind, he caught an attack of asthma, which cut him off on 26th March 1863, at Algiers, near which city his remains were buried.

Egg was a gifted and well-trained painter of *genre*, chiefly in the way of historical anecdote, or of compositions from the poets and novelists. As years progressed, he developed in seriousness of subject-matter and of artistic treatment; and at the time of his death he might be ranked among our best painters in his particular class—clever, skilled, and observant—although he had not any marked originality of point of view or of style. Among his principal pictures may be named:—1843, the Introduction of Sir Pierce Shafton and Halbert Glendinning (from Scott's *Monastery*); 1846, Buckingham Robuffed; 1848, Queen Elizabeth discovers she is no longer young; 1850, Peter the Great sees Catharine for the first time; 1854, Charles I. raising the Standard at Nottingham (a study); 1855, the Life and Death of Buckingham; 1857 and 1858, two subjects from Thackeray's *Esmond*; 1858, Past and Present, a triple picture of a faithless wife; 1859, the Night before Nasoby; 1860, his last exhibited work, the Dinner Scene from *The Taming of the Shrew*. The National Gallery contains one of his earlier pictures, Patriotic entertaining two Ladies, from the *Diable Boiteux*; it was painted in 1844.

Egg was rather below the middle height, with dark hair and a handsome well-formed face; the head of Peter the Great (in the picture of Peter and Catharine, which may be regarded as his best work, along with the Life and Death of Buckingham) was studied, but of course considerably modified, from his own countenance. He was manly, kind-hearted, pleasant, and very genial and serviceable among brother-artists; social and companionable, but holding mainly aloof from fashionable circles. As an actor he had uncommon talent. He appeared among Dickens's company of amateurs, in 1852 in Lord Lytton's comedy *Not so Bad as we Seem*, and afterwards in Wilkie Collins's *Frozen Deep*, playing the humorous part of Job Want.

EGINHARD is best known as the biographer of Charlemagne. His name is variously spelled in manuscripts. Einhardus, Einhartus, Ainhardus, Heinhardus, are the earliest forms. In the 10th century it was altered into Agenardus, and out of this form arose Eginardus and Eginhardus. The French and English languages have adopted this later form; but it is unquestionably wrong, and the weight of authority is for Einhardus or Einhartus. The circumstances of his life are involved in considerable obscurity, owing partly to the want of information and partly to the doubtfulness or indefiniteness of our authorities. According to the statement of Walafidus Strabo, a contemporary, he was born in the district which is watered by the river Maine in the modern duchy of Hesse-

Darmstadt. Teulet has disputed the genuineness of the document in which the statement is contained, because "it exists only in one manuscript of the 15th century, and it contains an evident anachronism." The anachronism, however, is a mistake on the part of Teulet, for he understands by "pedagogium Sancti Bonifacii" a school taught by St Boniface, whereas it plainly means a school in the monastery of St Boniface, as Jaffé takes it. The date of his birth can only be conjectured, but it must be somewhere about the year 770 A.D. His parents were noble, and probably their names were Einhart and Engilfrit. He was educated at the monastery of Fulda. There is documentary evidence that he was resident in that place in the years 788 and 791. Owing to his intelligence and ability he was transferred from the monastery by its abbot Baugolfus to the palace, where he became intimate with the emperor and his family, and received commissions of great trust and importance. His removal to the palace took place not later than 796.

He was entrusted by the emperor with the charge of public buildings. He thus became one of the imperial ministers, and resided with the emperor at Aix-la-Chapelle. In reference to his artistic skill he received the Scripture name of *Beseleel* (Exod. xxxi. 2ff, and xxxv. 30ff), according to a fashion then prevalent of giving ancient names to contemporaries. Some suppose that he constructed the basilica at Aix-la-Chapelle and the other buildings mentioned in chapter xvii. of his *Life of Charlemagne*, but there is no express statement to that effect. The emperor employed him in 806 as legate to Rome to obtain the Pope's signature to a will which he had made in regard to the division of his empire. Hence the inference has been drawn that he was the emperor's secretary; but no contemporary ascribes this office to him.

It was owing to Eginhard's influence that in 813 Charlemagne made his son Louis partner in the empire. Louis, on becoming sole emperor, proved grateful to Eginhard, retained him in the office of head of public works, made him tutor to his son Lothaire in 817, and showed him every mark of respect.

Eginhard married Imma, a noble lady, a sister of Bernharius, who was bishop of Worms and abbot of the monastery of Wizenburg. Later tradition converted Imma into the daughter of Charlemagne, and invented a romantic story in regard to the marriage of Eginhard and Imma.¹ It is doubtful whether he had any offspring. Eginhard addresses a letter to a person called Vussin, whom he styles "filii," "mi nate." These expressions and the tenderness of the language almost compel the belief that Vussin was his son, but as Vussin is never mentioned in several deeds in which his interests would have been concerned, and in which the names of Eginhard and Imma appear, some have supposed that Vussin was merely a spiritual son.

On January 11, 815, Louis bestowed on Eginhard and his wife the domains of Michelstadt and Mulinheim in the

Odenwald on the Maine. In the document conveying this property to him he is simply called Einhardus, but in a document of June 2, 815, he is called abbot. In becoming abbot he did not dismiss his wife. After this period we find him at the head of several monasteries, Blandigny of Ghent, Fontenelle in the diocese of Ronen, St Bavon of Ghent, St Servais of Maestricht, and St Cloud (but not the St Cloud near Paris), and he had also charge of the church of St John the Baptist at Pavia.

Eginhard began to grow tired of the intrigues and troubles of court life, and in 830 finally withdrew to Mulinheim, which he named Seligenstadt, where he had erected a church to which he had transported the relics of St Marcellinus and St Peter. His wife helped him in all his efforts, and her death in 836 caused him bitter grief. The emperor Louis visited him in his retreat the same year, probably to console him, but Eginhard did not long survive his wife, for he died March 14, 840.

Eginhard was a man of culture. He had reaped the benefits of the revival of education brought about by Charlemagne, and was on intimate terms with Alcuin. He was well versed in Latin literature, and knew Greek. He was very small in body, a feature on which Alcuin wrote an epigram. His most famous work is his *Vita Caroli Magni*, written in imitation of the *Lives* of Suetonius. It is the most reliable account of Charlemagne that we have, and a work of some artistic merit. It was written soon after the death of the great emperor. It was very popular in the Middle Ages. Pertz collated upwards of sixty MSS. for his edition.

The other works of Eginhard are—(1) *Annales Francorum*, extending from 741 A.D. to 829 A.D.; some doubt their authenticity, without good reason; (2) *Epistolæ*, handed down only in one MS, now at Laon and of considerable importance for the history of the times; (3) *Historia Translationis Beatorum Christi Martyrum Marcellini et Petri*, written in 830, and giving a curious narrative of how the bones of the martyrs were stolen and conveyed to Seligenstadt, and what miracles they wrought. To this is added a poem on the same subject. A treatise written by him, *De Adoranda Cruce*, has not come down to us.

The literature on Eginhard is very extensive, almost all who deal with Charlemagne, early German literature, and early French literature treating of him. The fullest and best accounts are given by Teulet and Jaffé in their editions.

The modern editions of Eginhard's works are by Pertz in vols. i and ii of his *Monumenta Germaniæ Historica*, Hanover, 1826–1829; Teulet, *Einhardi omnia quæ extant Opera*, Paris, 1840; Migne, *Patrologia Latina*, tom. 104, Paris, 1866 (the *Life of Charlemagne* is in vol. 97), and Philip Jaffé in vol. iv. of his *Bibliotheca Rerum Germanicarum*, Berlin, 1867. Teulet's is the handiest and most complete edition, and he deserves special praise in connection with the letters. Pertz and Jaffé published the *Life of Charlemagne* separately for the use of schools. Teulet gives a full account of all previous editions, of the MSS, and of translations. Some of the other editions contain bibliographical references. A translation of the *Life of Charlemagne* has appeared in English by W. Glaister, London, 1877 (J. D.)

EGLANTINE (E. Frisian, *egeltiere*; French, *aiglantier*), a name for the sweet-brier, *Rosa rubiginosa*, and for *R. lutea*, another species of Lindley's tribe of *Rosæ Rubiginosæ*, and apparently the *R. Eglanteria* of Linnæus. The signification of the word seems to be thorn-tree or thorn-bush, the first two syllables probably representing the Anglo-Saxon *egla*, *egle*, a prick or thorn, while the termination is the Dutch *tere*, *taere*, a tree (see Wedgwood, *Dict. Eng. Etymology*). Eglantine is frequently alluded to in the writings of English poets, from Chaucer downwards. Milton, in *L'Allegro*, l. 48, is thought by the term "twisted eglantine" to denote the honeysuckle.

¹ The story of his courtship, although apocryphal, deserves to be noticed, as it frequently appears in literature. He is said to have made a practice of visiting the emperor's daughter secretly by night. On one of these occasions a fall of snow occurred which made it impossible for him to walk away without leaving footprints that would have led to his detection. The risk was obviated by an expedient of Emma, who carried her lover across the court-yard of the palace on her back. The scene was witnessed from a window by Charlemagne, who related it next morning to his counsellors and asked their advice. The severest punishments were suggested for the clandestine lover, but Charlemagne rewarded the devotion of the pair by consenting to their marriage. The story is inherently improbable, and it is further discredited by the facts that Eginhard himself does not mention Emma among the number of Charlemagne's children, and that a story similar in its details has been told of a daughter of the emperor Henry III.

EGLINTON, ARCHIBALD WILLIAM MONTGOMERIE, THIRTEENTH EARL OF (1812–1861), lord lieutenant of Ireland, was born at Palermo, September 29, 1812. He was the grandson of Hugh, the twelfth earl, and only son of Archibald, Lord Montgomerie, who at the time of his son's birth held a diplomatic post in Sicily. He was only in his eighth year when he succeeded to the title and estates on the death of his grandfather, in December 1819. The young earl was educated at Eton College; and for some time his chief object of interest was the turf. He had a large racing stud, and won success and a reputation in the sporting world. In 1839 his name became more widely known in connection with a tournament which he projected, and which was held at his seat in August of that year. At this attempted revival of mediæval pageantry, one of the knights was Prince Louis Napoleon, afterwards emperor of the French. The earl of Eglinton was a staunch adherent of the Conservative party, and, on the formation of the first Derby administration in February 1852, he was called from his comparative retirement to fill the office of lord lieutenant of Ireland. He retired with the ministry in the following December, having by the manliness of his character, his affability, and his princely hospitality made himself one of the most popular of Irish viceroys. On the return of the earl of Derby to office in February 1858, the earl of Eglinton was again appointed lord lieutenant, and discharged the duties of this post till June 1859. Before his second retirement he was created earl of Winton in the peerage of the United Kingdom. He had been elected in 1852 lord rector of Glasgow University. The earl was twice married; first, in 1841, to Theresa, widow of Captain R. H. Cockerell, R.N., by whom he had four children. The countess died in December 1853; and in 1858 the earl married the Lady Adela Capel, only daughter of the earl of Essex. He lost his second wife in December 1860, and died suddenly himself at St Andrews, October 1, 1861. He was succeeded in the earldom by his eldest son, Archibald William, Lord Montgomerie.

EGMONT (EGMOND), LAMORAL, COUNT OR, Prince of Gavre (1522–1568), was born in Hainault in 1522. He was the younger of the two sons of John IV., count of Egmont, by his wife Francisca, princess of Gavre, and succeeded to the title and estates on the death of his older brother Karl, about 1541. In this year he served his apprenticeship as a soldier in the expedition of the emperor Charles V. to Algiers, distinguishing himself in command of a body of cavalry. In 1545 he married Sabina of Bavaria, sister of the Elector Palatine, and the wedding was celebrated with great pomp at Spiers in the presence of the emperor. Soon afterwards Egmont was invested with the order of the Golden Fleece. He accompanied the emperor in the various campaigns and progresses of the following years, was with him at the unsuccessful siege of Metz (1553), and in 1554 was sent to England as head of an embassy to seek the hand of Queen Mary for Philip (II.) of Spain. He was present at their marriage solemnized shortly after at Winchester. In the summer of 1557 Count Egmont was appointed commander of the Spanish cavalry in the war with France; and it was by his vehement persuasion that the battle of St Quentin was fought. The victory was determined by the brilliant charge which he led against the French. The reputation which he won at St Quentin was raised still higher in 1558, when he encountered the French army under De Thermes at Gravelines, on its march homewards after the invasion of Flanders, totally defeated it, and took Marshal de Thermes and many officers of high rank prisoners. The battle was fought against the advice of the duke of Alva, and the victory made Alva Egmont's enemy. But the count now became the idol of his countrymen, who looked upon him

as the saviour of Flanders from devastation by the French. He was nominated by Philip stadtholder of the provinces of Flanders and Artois. At the conclusion of the war by the treaty of Cateau Cambresis, Egmont was one of the four hostages selected by the king of France as pledges for its execution. As stadtholder he now showed some sympathy with the popular discontent excited by the Spanish Government, and particularly by Cardinal Granvella, minister to the regent Margaret. As a member of the council of state he joined the prince of Orange in a vigorous protest addressed to Philip (1561) against the proceedings of the minister; and two years later he again protested in conjunction with the prince of Orange and Count Horn. He was invited by Philip to go to Spain to confer with him on the subject of the remonstrance, but he declined. Egmont, however, who was a strict Catholic, afterwards spoke in less hostile terms of the minister; and, at the same time that he was courting the favour of the middle classes, he was becoming more a favourite at the court of the regent. In January 1565 he accepted a special mission to Spain to make known to Philip to some extent the state of affairs in the Netherlands and the demands of the people. At Madrid the king gave him an ostentatiously cordial reception, and all the courtiers vied with each other in lavishing professions of respect upon him. But earnest discussion of the real object of the mission was evaded by the king, and Egmont had to return to the Netherlands loaded only with fine words of flattery and promise. At the very same time instructions were sent to the regent to abate nothing of the severity of persecution, and the Inquisition was re-established. Egmont was indignant, and the people were in a state of frenzied excitement. In 1566 a confederation of the nobles (*Les Gueux*) was formed, the document constituting it being known as the Compromise. Egmont then withdrew to his government of Flanders, and showed himself, after some vacillation, an unscrupulous supporter of the Spaniards and fierce persecutor of heretics. In the summer of 1567 the duke of Alva with an army of veterans arrived in the Netherlands, to supersede the regent Margaret, and to crush with the strong hand the popular opposition. One of his first acts was the treacherous seizure of Counts Egmont and Horn, who were imprisoned at Ghent. A sham process was begun against them, and after some months they were removed to Brussels, where sentence was pronounced by Alva himself on the 4th June 1568. Egmont was declared guilty of high treason and condemned to death. It was in vain that the most earnest intercessions had been made in his behalf by the emperor Maximilian, the order of the Golden Fleece, the states of Brabant, the electors of the empire, and the regent herself. Vain, too, was the pathetic pleading of Egmont's wife, who with her eleven children was reduced to want, and had taken refuge in a convent. Egmont was beheaded at Brussels the day after the sentence was pronounced, June 5. He met his end with calm resignation; and in the storm of terror and exasperation to which this tragedy gave rise Egmont's failings were forgotten, and he and his fellow victim to Spanish tyranny were glorified in the popular imagination as martyrs of Flemish freedom. This memorable episode proved to be the prelude to the famous revolt of the Netherlands, the issue of which was independence. Goethe made it the theme of a tragedy. In 1865 a monument to Counts Egmont and Horn, by Fraiken, was erected at Brussels.

Full details may be found in Bercht's *Geschichte des Grafen Egmont* (1810); Clouet's *Eloge historique du Comte d'Egmont* (1825); Prescott's *History of Philip II.* (1835–59); Motley's *Rise of the Dutch Republic* (1856); and Juste's *Le Comte d'Egmont et le Comte de Hornes* (1862).

EGRET. See HERON.

1844, the extent of cultivated land has increased. This has been chiefly due to works of irrigation in Lower Egypt, the increased cultivation of cotton, and the greater facility of transport. The increase cannot, however, be very large.

Divisions.—The ancient like the modern Egyptians followed the natural division of the country into two tracts, the valley of Upper Egypt and the plain of Lower Egypt. The names in hieroglyphics are to-res, the "south land" (compared, with the article prefixed, p-to-res, to Pathros by M. de Rougé), and to-mohut, the "north land." The two were divided by the southern boundaries of the highest nomes of Lower Egypt, the Memphite and Heliopolite, and thus the political boundary was somewhat south of the position where the valley extends into the plain. The most southern nome of Upper Egypt was called that of Nubia, and began at Siſsilis. The Greek and Roman division excludes the Memphite Nome from Lower Egypt.

It is not known at what date Egypt was first divided into the provinces called Nomes. They are noticed in inscriptions of Dynasty IV. (Brugsch, *Geogr. Inschr.*, i. 93), and their symbol occurs in the name of Hesp-ti, "the two nomes," fifth king of Dynasty I., Manetho's Usaphaidos.¹ The hieroglyphic name is hesp. In late inscriptions the term (p-)tesh occurs, which is also the demotic form, and the origin of the Coptic (*Id.* i. 94, 95). The number of nomes is somewhat different in the various ancient Egyptian lists, all of which, except fragments, are of the Greco-Roman age. Probably the number varied at different times. Dr Brugsch conjectures the true number to be forty-two, considering the forty-two judges of the dead (*Ritual*, ch. 125) as called from the chief towns of the kingdom to a great tribunal (*Geogr. Inschr.*, i. 99), which he thinks represents the earthly court described by Diodorus Siculus (i. 75).—(*Geogr. Inschr.*, i. 124.)

There was a double system of names for the nomes,—the sacred, usual in hieroglyphics, and the vulgar, taken from the capitals, and preserved in Greek in transcriptions or translations. In consequence of this double system the identification of the hieroglyphic names with those of the Greeks and Romans is not always certain. This is the case in Lower Egypt, where the form of the country makes it hard to determine the exact geographical relation intended by any order. On account of this difficulty, and because the hieroglyphic names are of inferior importance in the geography of Egypt, they are not here given. (See Brugsch, *Geogr. Inschr.*, i. 93, seqq.)

By the Greeks and Romans Egypt was divided into the Delta or lower country, and the Thebais or upper country. The third division, the so-called Middle Egypt, first occurs in Ptolemy as the Seven Nomes, Ἑπτὰ νομοί, or Hepta-

nomis, Ἑπτανομίς. This new division, and the transfer of the Memphite Nome from Lower Egypt to the Heptanomis, are the chief innovations, for the fanciful divisions of Lower Egypt in Ptolemy are no doubt theoretical.

The following list of the nomes is taken from Parthey's *Vocabularium Coptico-Latinum*, compared with the same author's *Erdkunde des alten Aegyptens*, Berl. Akad., 1858. The authorities are Herodotus, Agatharchides, Strabo, Pliny, Ptolemy, the coins of the nomes struck under Trajan, Hadrian, and Antoninus Pius, the last indicated by the abbreviation Nu., and other sources. The letters L., H., and T. indicate Lower Egypt, the Heptanomis, and the Thebais, as the divisions to which nomes thus designated are known to belong.

Sacy's Abd-Allatif It was made in the year of the Flight 777 (A.D. 1375-6), [recording the census of 715, A.D. 1315-6], and may be rather underrated than the reverse. The estimate of M. Mengin (*Histoire de l'Égypte*, ii. 342-344) shows that in 1821 the extent of the cultivated land was much less; but since that period considerable tracts of waste land had been rendered fertile" (*Englishman in Egypt*, i. 85, note). In the *Description de l'Égypte* there is an excellent memoir on the superficies of that country by Col Jacotin, who computes the space which the Nile does or can water or fertilize, including its bed, north of the first cataract, at 9582 39 square geographical miles, of which but 5626 59 were in a state of cultivation or fit for cultivation. The space actually under cultivation was found by M. Estébe to be 5469 86 square miles, but it is stated that 2735 07 more may have been anciently cultivable, of which much might be reclaimed. *Description de l'Égypte*, xviii. ii. 101, seqq. The close agreement of Mr Lane's estimate with Col. Jacotin's shows that the bases of both were accurate, and the difference from M. Mengin's may be explained by the disasters which preceded the establishment of Mehemet Ali as pasha.

¹ M. de Rougé has already noticed the possibly commemorative character of two other not much later royal names, Bakau and Bi-n-uter (*Six Prem Dyn*, 243, 244), and this may therefore perhaps have been of the same kind

It is very remarkable that the Arsinoite Nome of the Hoptanomis does not appear in the hieroglyphic lists, because Sebek, the crocodile-headed divinity there worshipped was, at least in later times, disliked in most parts of Egypt (Brugsch, *Hist.*, 2 ed., 109, 107).

The *Notitia Dignitatum*, composed under Theodosius II., A.D. 408-450, gives a new a division of Egypt into four provinces—Ægyptus, Augustamnica, Arcadia, and Thebais. Roughly the first comprised all Lower Egypt except the part east of the Delta, which was assigned to the second, and Arcadia appears to have succeeded the Heptanomis (Parthey, *Erdkunde*, 518, taf. vii.).

About the time of Justinian I. this division is found to be further developed, according to the statements of Hierocles. Egypt contained six eparchies:—1. Egypt Proper, *Αἴγυπτιακή*, the west of Lower Egypt to the Sebennytic branch of the Nile; 2. The First Augusta, *Αἴγυπτος α'*, the north-eastern part of Lower Egypt to the Syrian border; 3. The Second Augusta, *Αἴγυπτος β'*, the territory southward of the First Augusta; 4. Arcadia, *Ἀρκαδία*, the earlier Heptanomis; 5. The Nearer Thebais, *Θηβαίς ἡ ἔγγιστα*, extending to Panos, or Panopolis, and including the Great Oasis; 6. The Upper Thebais, *Θηβαίς ἡ ἄνω*, as far as Philæ. The division into nomes had evidently been almost effaced at this time (*Id.* 520, taf. ix.).

The Copts preserved the oldest division of the country, and called Lower Egypt, the Northern Region, *ⲙⲉⲛⲓⲩⲧ* (Mem.), *ⲙⲉⲛⲓⲩⲧ*, &c. (Sah.), Upper Egypt, the Southern Region, *ⲣⲏⲥ* (Mem.), *ⲙⲁⲣⲏⲥ* (Sah.) The names of the nomes were also known to them, and are given by Champollion in *L'Égypte sous les Pharaons*.

Like the Copts, the Arabs generally know of but two divisions, the names of which are such as the people of the desert would naturally give to the country watered by the Nile. Lower Egypt is called Er-Reef, the cultivated, or fertile, and Upper Egypt, Es-Sa'eed, the happy, or fortunate.

Under the Memlook sultans of the Bähree dynasty, as we learn from the list appended to De Sacy's *Abd-Allatif*, referring to A.H. 715 (A.D. 1315-6), the provinces of Egypt were less numerous than the ancient nomes. They are for Lower Egypt—the territory of Cairo and the provinces of Kalyoob, the Sharkeeyeh, the Dakahleeyeh, Ed-Dimyât, the Gharbeeyeh, Menoof, Abyar and Benec-Nasr, the Boheyreh, Fooweh, Nesterawiyeh, Alexandria, and El-Geezeh; and for Upper Egypt—the provinces of Atfeeh, the Feiyoom, Behnesè, Ashmooneyn, Manfaloot, Asyoot, Akhmeem, and Koos. At the time of the French occupation the provinces had been reduced in number to sixteen, and the division of the Middle Provinces introduced, thus reviving the Heptanomis. The Northern Provinces, El-

Akaleem el-Bahreeyeh, were the Gharbeeyeh, that of Er-Rasheed, the Boheyreh, that of El-Mansoorah, the Manoo-feeyeh, that of Ed-Dimyât, the Sharkeeyeh, the Kalyoobeeeyeh, and that of El-Geezeh. The Middle Provinces, El-Akaleem el-Wustaneeyeh, were that of Atfeeh, the Feiyoom, and those of Benec-Suweyf or Behnesè, and of El-Minyeh or Ashmooneyn.¹ The Southern Provinces, El-Akaleem el-Kibleeyeh, were those of Asyoot, Gîrgà, and Kinè. There is no doubt that these provinces sometimes correspond to the ancient nomes, though generally composed of the territories of more than one. (Cf. Jomard in *Descr. de l'Égypte*, 2d ed. ix. 594, 595.) By Mehemet Ali a new division was formed into districts governed by a mudeer, of which Lower Egypt, including a small portion of the Middle Provinces, contained four, and the rest of Egypt three. At the present time Egypt is divided into fifteen provinces, each governed by a mudeer.

I. LOWER EGYPT—

- | | |
|---------------------|------------------------|
| 1. Bohoyreh | chief town, Demenhoor. |
| 2. El-Geezeh .. | El-Geezeh. |
| 3. Kalyoobeeeyeh .. | Kalyoob |
| 4. Sharkeeyeh .. | Zagazzeg. |
| 5. Menoofceeyeh .. | Sheybeen |
| 6. Gharbeeyeh .. | Tantah |
| 7. Dakahleeyeh .. | Mansoorah. |

II. MIDDLE EGYPT—

- | | |
|---|---------------|
| 1. Benec-Suweyf and Feiyoom .. | Benec-Suweyf. |
| 2. El-Minyeh and Benec-Mazar (double province) .. | El-Minyeh. |

III. UPPER EGYPT—

- | | |
|------------------------|---------|
| 1. Asyoot | Asyoot. |
| 2. Gîrgà | Sooahg. |
| 3. Kinè and Kuseyr. .. | Kinè. |
| (double province) | |
| 4. Isnè .. | Isnè. |

—Edmord (*L'Égypte*, 269, 270).

It will be readily understood that much confusion prevails as to the divisions of the country, more especially at times when an arbitrary administrative division has been used side by side with a popular one, depending upon what nature and artificial aids, such as canals and dikes, have done to map out the country.

The general appearance of Egypt is remarkably uniform. The Delta is a level plain richly cultivated, and varied alone by the lofty dark-brown mounds of ancient cities, and the villages in groves of palm-trees, standing on mounds often if not always ancient. We sometimes see groves of palm-trees besides those around the villages, but other trees are, except in some parts, rare. In Upper Egypt the valley is in as rich a state of cultivation, but very narrow and bounded by mountains of no great height, which hem it in. They form the edge of the desert on either side of the valley, which has been cut through a rocky table-land by the river. They rarely take the form of peaks. Sometimes they approach the river in bold promontories, and at others are divided by valleys with the beds of torrents which flow only at very long intervals. The bright green of the fields, the reddish-brown or dull green of the great river, and the tender tints of the bare yellow rocks, beneath the deep blue sky, always form a beautiful view. In form the landscape varies little and is not remarkable; in colour its qualities are always splendid, and under a general uniformity show continual variety.

Climate.—The climate of Egypt, being remarkably equable, is healthy to those who can bear great heat, and who avoid the unwholesome tracts of the country, such as the

¹ M. Jomard states that the older appellations were used for the two provinces of Benec-Suweyf and El-Minyeh, though these towns had succeeded the earlier chief places after which the provinces were named.—*Descr. de l'Égypte*, ix. 594.

northern coast, where there are extensive salt-marshes. Upper Egypt is healthier than Lower Egypt. The least healthy time of the year is the latter part of autumn, when the inundated soil is drying. In the desert, at a very short distance from the cultivable land, the climate is uniformly dry and unvaryingly healthy. Egypt, however, is unsuitable as a permanent residence to Europeans who do not greatly modify their mode of life;¹ and it is almost impossible to rear European children there; but if they arrive after the age of ten or a little more they do not usually feel its ill effects.² As a resort for invalids Egypt cannot be recommended without caution. Persons suffering from asthma and bronchitis are likely to gain benefit from a Nile-voyage, unless the season is unusually cold. The climate of the desert does not in all cases suit them, the small particles of sand which are inhaled increasing the irritation. The desert air is undoubtedly good for consumption, and a wise plan is to encamp near Cairo, or still better to find some kind of house within the limits of the desert; and there are ancient sepulchral grottoes at Thebes and other sites which afford excellent quarters for any one who will take the pains to build a court and a few rooms in front of them. A Nile-voyage cannot be so safely recommended. The climate on the river itself is more changeable than elsewhere, and often in winter far colder than is good for delicacy of the lungs. No one should visit Egypt in the winter without heavy as well as light clothing.

The atmosphere is remarkably dry and clear, except on the sea-coast; and even the humidity which is the consequence of the spreading of the inundation is scarcely felt but by its rendering the heat more oppressive. Sometimes a white fog, very dense and cold, rises from the river in the morning, but it is of rare occurrence and short duration. The heat is extreme during a great part of the year, but it is chiefly felt when accompanied by the hot winds of spring and the sultry calm of the season of the inundation. The winter is often comparatively severe in its cold, especially as the domestic architecture is intended to protect rather from heat than cold. "The general height of the thermometer in the depth of winter in Lower Egypt, in the afternoon and in the shade is from 50° to 60°; in the hottest season it is from 90° to 100°, and about 10° higher in the southern parts of Upper Egypt" (*Mod. Eg.*, *Introd.*)

On the coast of the Mediterranean rain is frequent, but in other parts of Egypt very unusual. At Cairo there is generally one heavy storm in the winter, and a shower or two besides, the frequency of rain having increased since the growth of Ibrahim Pasha's plantations between the city and the river. At Thebes a storm occurs but once in about four years, and light rain almost as rarely.

The wind most frequently blows from the N.W., N., or N.E., but particularly from the first direction. The proportionate prevalence of these winds to those from all the other quarters, in the year, is about 8 to 3; but to those from the S., S.E., and S.W., about 6 to 1. (*Clot-Bey, Aperçu Général sur l'Égypte*, i. p. 30.) The northerly winds are the famous Etesian winds of Herodotus (ii. 20), which enable boats constantly to ascend the Nile against its strong and rapid current, whereas in descending the river they depend on the force of the stream, the main-yard being lowered. These winds also cool the temperature during the summer months. The southerly winds are often very violent, and in the spring and summer, especially in April and May, hot sand-winds sometimes blow from the south, greatly raising the temperature, and causing especial suffering to Europeans. The famous Simoom, properly

called Samoom,³ is a much more violent hot sand-wind, which is more usual in the desert than in the cultivated tracts, but in either occurring only at long intervals. It is a kind of hurricane, most painful to experience, and injurious in its effects. (*Englishwoman in Egypt*, i. 96, 97.) The zóbb'ah is a common but remarkable phenomenon. It is a very lofty whirlwind of sand resembling a pillar, which moves with great velocity. Mr Lane measured some with a sextant, and found them to be between 500 and 700 feet in height, and one to have an altitude of 750 feet. When crossing the Nile a zóbb'ah frequently capsizes any boat which may be in its way, and of which the main-sheet is tied by the carelessness of the boatmen instead of being held. (*Id.*, *loc. cit.*; *Modern Egyptians*, chap. x.) It may be mentioned that a sudden gust of wind from a valley in the mountains is equally dangerous when the sheet is tied, and a third danger is the attempt to move during a southerly gale, when the long shallow Nile-boat is easily caught broadside and capsized.

One of the most interesting phenomena of Egypt is the mirage, which is frequently seen both in the desert and in the waste tracts of uncultivated land near the Mediterranean; and it is often so truthful in its appearance that one finds it difficult to admit the illusion.

Diseases.—Notwithstanding the fineness of the climate, the stranger who visits Egypt is struck by the signs which he sees everywhere of the prevalence of many serious diseases, and in the first half of this century he might have witnessed the effects of a great epidemic of the plague or the cholera. Yet he should remember the poverty of the great mass of the inhabitants and the insufficiency of their food (both due to the selfish rapacity of the Government), the insufficient training of the native medical practitioners, the false system of many of the foreigners established in the country, and the reluctance of the natives to take medical advice. Ophthalmia when neglected is frequently followed by blindness, and dysentery in the same circumstances is very often fatal.

The plague has been the greatest scourge of Egypt. We cannot tell whether the pestilences mentioned by Manetho as having occurred in the reign of one of the most ancient kings were the same as the modern plague; it seems, however, to be alluded to in the Bible as peculiarly Egyptian (*Zech.* xiv. 18). In 1835 there was an epidemic of plague of extreme severity, during which there died in Cairo a number of the inhabitants equal to the whole adult male population (*Modern Egyptians*, *Introduction*). The last occurrence of the disease was in 1843, when the mortality was comparatively insignificant. The immunity which Egypt has enjoyed for more than thirty years, in which interval there would ordinarily have been several plagues, has been attributed to the sanitary measures of the Egyptian Government, and no doubt these may have somewhat contributed to this result. It should, however, be remembered that the plague is always imported into Egypt, and that there have been no severe epidemics of undoubted plague elsewhere in the period.

This disease has usually first appeared in the east and south coasts of the Mediterranean, and part of the north coast, and when epidemic seems to pursue a similar course to the cholera in advancing steadily from place to place. In Egypt it usually appears first at Alexandria in the winter

¹ Beer, wine, and all alcohol should be very sparingly used, and little meat eaten in the hot season.

² One resident at Alexandria adopted with success the method of sending her children to sea as soon as any weakness showed itself.

³ Of the term samoom Mr Lane writes, "In the present day it is commonly applied to a violent and intensely-hot wind, generally occurring in the spring or summer, in Egypt and the Egyptian deserts usually proceeding from the south-east or south-south-east, gradually darkening the air to a deep purple hue, whether or not (according to the nature of the tract over which it blows) accompanied by clouds of dust or sand, and at length entirely concealing the sun, but seldom lasting more than about a quarter of an hour or twenty minutes." —*Arabic Lexicon*, s.v., pt. iv. 1420.

or spring, and if the earliest cases occur towards the close of the year, one may be sure of a plague of great severity and long continuance. At first the cases are generally few, but they gradually increase, and in the hottest weather attain their maximum. The disease is not long in travelling from Alexandria to Cairo, but it rarely ascends much higher up the river, and has seldom been known at Thebes in modern times. Many medical writers have denied the contagious character of the plague, in particular Clot-Bey, a French physician, who was long chief medical officer of the Egyptian Government, and who published a treatise on the subject (Clot-Bey, *De la Peste*); yet the evidence on the other side is too strong to be rebutted. An epidemic of plague is greatly to be dreaded in the present circumstances of Egypt. Rapid communications would readily bring the disease to Europe, and the interests of commerce would stand in the way of the reasonable precaution of quarantine. It is stated that the plague is endemic in the marshes of Chaldæa. Surely it would be well if the European Governments were to appoint a commission for the investigation of the disease and to ascertain what, if any, is the value of the sanitary measures of the Turkish Government.

Dysentery is an extremely common malady, and causes very large mortality. It may usually be traced to a careless course of diet, and especially to eating uncooked vegetables, unripe fruit, or other unwholesome food, and to drinking brackish water. Mr Lane has published a mode of treatment which has been attended with extraordinary success (*Modern Egyptians*, App E. of all later editions). Asiatic cholera visited Egypt in its westward course on the first two occasions of its appearance in Europe. According to the Government returns, which were probably below the truth, nearly 200,000 persons perished from the disease in all Egypt during the great cholera of 1848. It is remarkable that after each of these great epidemics the disease appeared a second time, but with far less destructive results. Among the diseases most dreaded by the European residents is liver-complaint. These who abstain from alcoholic drinks, or use them with extreme moderation, escape the complaint altogether, or suffer from it in a comparatively mild form. Hemorrhoids and herniæ are among the commonest maladies. Skin diseases have been at all times very prevalent in Egypt. Leprosy is now well known, but not common, unlike elephantiasis, which in more than one form has numerous victims. Small-pox was formerly very severe, but it has been checked in its virulence by vaccination. The so-called guinea-worm occurs, but it is perhaps not indigenous.

Of the diseases of the eye, ophthalmia is the most formidable, from its prevalence and malignant character; yet perhaps no malady more readily yields to treatment if promptly used. Where the predisposition exists, a slight cause, such as the irritation occasioned by a grain of dust or sand, is enough to produce an inflammation, which, if not checked, inflicts a lasting injury if it does not produce blindness. For this disease Mr Lane has published a very efficacious mode of treatment (*Mod. Eg.*, App. E).

Clot-Bey affirms that pulmonary consumption is extremely rare among the native inhabitants (*Aperçu*, ii. 372), yet another physician asserted (but not in print) that he had met with not a few cases in a short practice. Asthma and bronchitis are among the common disorders. The occurrence of *coup-de-soleil* is not unusual, but it is rarely attended with fatal results, probably on account of the sobriety of the people. Madness is common, generally in the form of idiocy. Maniacs alone are confined; idiots are regarded with much respect as saints, and it is probable that some persons feign idiocy to become objects of popular veneration, supported by alms. One of the Memlook

sultans, Katâoon, following the example of Saladin (*Abulfedæ Annales*, ed. Reiske, iv. 30, 31) founded a madhouse, or *mâristân*, at Cairo, which was still used thirty years ago (*Englishwoman in Egypt*, i. 166). Its inmates were subsequently transferred to a modern hospital. Nervous affections are uncommon, probably owing to the calm life which the inhabitants lead. Rheumatism is of more usual occurrence; but, according to Clot-Bey, gout is unknown (*Aperçu*, ii. 377). It is well worthy of notice that, although ownerless dogs are very common in Cairo and the other towns, and watch-dogs are kept by the villagers, canine madness and hydrophobia are unknown; but Clot-Bey is probably in error when he says that rabies has never been observed in Egypt (*id.* ii. 78), for the Coptic prayer-books contain a prayer to be used for a person suffering from hydrophobia,¹ and this is not likely to have been derived from a foreign source. (For an account of the diseases of Egypt, see Clot-Bey's *Aperçu Général* and *De la Peste*. and *Descr. de l'Égypte*, xiii. 29).

Geology.—In considering the geology of Egypt, its deserts claim our first notice. By a desert is generally understood a wide plain of shifting sand; but this is usually an erroneous description of such a tract, and especially inapplicable to the deserts which border the valley of the Nile. These are raised mountain regions, the surface of which is often covered with sand, debris, and pebbles, intersected by valleys, and diversified, in the case of the western desert, by some oases.

On both sides of the Nile the mountains are limestone, until a little above Thebes, where the sandstone commences. At the First Cataract red granite and other primitive rocks burst through the sandstone beneath the bed of the Nile, and for a considerable space on the east, obstructing the course of the river by numerous small islands and rocks, and thus forming the rapids. In several places, chiefly on the eastern side, the mountains approach the river, and sometimes reach it. They are always utterly devoid of vegetation, and, except the granite, generally of a yellowish or reddish colour, though in some places they are greyish. Near the Cataract the sandstone mountains are partially covered with bright yellow sand in drifts. The mountains on both sides near the river are usually about 300 feet in height, and rarely much loftier. The highest point on the western bank at Thebes is four times that altitude. If one leaves the river and ascends the mountains, he finds a great rocky tract before him, the only easy paths through which are along valleys often very winding. The eastern desert gradually rises until about midway between the Nile and the Red Sea, where primitive rocks burst through the later formation, and the loftiest of them, a granite mountain called Gebel-Ghâreb (about lat. 28°), attains the height of about 6000 feet. In this portion of the desert are porphyry, breccia, and basalt rocks, which were anciently much prized for purposes of architecture and sculpture. The western desert is of a lower elevation, and is principally remarkable for its oases, which are deep valleys containing alluvial soil, but they are little productive except in dates. Their beauty and fertility have been naturally much exaggerated. Notwithstanding the inequalities of their surface, it is evident that the deserts rise towards the Red Sea, attaining their greatest height in the peninsula of Sinai, which is but a continuation of the same tract.

The most remarkable geological change which has been observed to have taken place in Egypt is one still in operation, the depression of the northern shore notwithstanding

¹ This is stated on the authority of the late Rev. J. R. T. Lieder of Cairo.

the constant deposit of the Nile, and the corresponding elevation of the southern part of the isthmus of Suez. The consequence of this change of level has been the ruin of places on the shore of the Mediterranean, the extension of the salt-marshes, and the drying up of a considerable part of the northernmost portion of the Gulf of Suez. The bed of the Red Sea may be traced for several miles north of Suez, which now stands at the head of the western gulf; and places far north of that town were on the coast in historic times.

The form of the plain and valley inclosed by the deserts is remarkably regular. In Lower Egypt the cultivable land little exceeds the limits of the ancient Delta, but greatly exceeds those of the space between the two remaining branches of the Nile. The northern coast is protected by shoals and a low range of sand-hills. To the south of these are extensive salt marshes and lakes, or waste tracts, and beyond, the cultivated land. The deserts on either side are of low elevation. To the east of the ancient Delta, a valley, the Wâdee-et-Tameykât, is in course of being reclaimed by the Sweet-Water Canal.

The form of the valley, or Upper Egypt, may be best seen on the map; its leading peculiarities may here be noticed. Its course is nearly north and south until just within the border of the Thebais, when it takes a southeasterly direction as far as the town of Girgâ, and then turns due east as far as Kinê, from which town it resumes its former direction. The mountains and desert on the western side throughout Upper Egypt, that is, above Cairo, are generally further from the river than those on the eastern side, which frequently reach to the water's edge. The difference is most remarkable as far as the town of Farshoot, by the course of the river about 350 miles above Cairo, and about 70 miles below Thebes. Near Farshoot begins a continuous series of canals, which flow parallel to the Nile, and near the Libyan chain, until they terminate in Lower Egypt, not far north of Cairo. Above Farshoot, the eastern mountains recede as far as a little above Thebes, and the western mountains gradually approach the Nile. Halfway between Thebes and the First Cataract, the cultivable soil is equally narrow on each bank. The greatest breadth of the cultivable land, all of which is not now cultivated, on the western bank seldom exceeds about 8 or 10 miles, and on the eastern bank, about 3 miles, but it is usually much narrower.

There is in Upper Egypt one striking deviation from the uniform character of the country. About 70 miles above Cairo, by the course of the Nile, an opening in the Libyan range leads to a kind of oasis, the Feiyoom, a fertile tract, lying in a hollow of the desert, and having at its further extremity a great lake of brackish water.

The Nile.—The chief natural feature of Egypt is the Nile, and the great phenomenon of the country the yearly inundation. With the ancient inhabitants the river had, according to their usage with such names, its two appellations, sacred and common. The sacred name was Hapi, the same as that of one of the four genii of Amenti (Hâdes) and of the bull Apis. The probable meaning is "the concealed" (Brugsch, *Geogr. Inscr.*, i. 77). The profane name was Atur, or Aur, usually with the epithet ââ, the great. The two forms, of which the first appears to be the older, the second the younger, mean "river," as is equally the case with the demotic and Coptic forms of Aur (*Id.* p. 78). There are at least three names of the Nile in the Bible,—Yêôr (יְאוֹר, יַאֲר), the same as the Egyptian name last mentioned, and probably of Egyptian derivation; Shichôr (שִׁיחֹר, שִׁיחֹר), "the black;" and "the river of Egypt," נְהַר מִצְרַיִם. The "torrent," or "brook of Egypt" (נְהַל מִצְרַיִם), spoken of as the western limit of Palestine, and so the eastern limit of Egypt, is either a desert stream

at Rhinocorura, now El-'Aroesh, or the Pelusiac or easternmost branch of the Nile¹

The Greek and Roman name Νεῖλος, Nilus, is certainly not traceable to either of the Egyptian names of the river, nor does it seem to be philologically connected with the Hebrew ones. It may be, like Shichôr, indicative of the colour of the river, for we find in Sanskrit, Nila, "blue," probably especially "dark blue," also even black, as Nilapan'ka, "black mud." The two great confluent of the Nile are now called the Bahr-el-Abyad, or "White River," and the Bahr-el-Azrak, or "Blue River," and the latter most nearly resembles the Nile in Egypt. As already noticed, Αἴγυπτος, in the *Odyssey*, is the name of the Nile (nase.) as well as of the country (fem.).

The Arabs preserved the classical name of the Nile in the proper name En-Neel النيل, or Neel-Misr مِصر النيل, the

Nile of Misr (Egypt). The same word signifies indigo.²

The modern Egyptians commonly call the river El-Bahr, "the sea," a term also applied to the largest rivers, and the inundation "the Nile," En-Neel; and the modern Arabs call the river Bahr-en-Neel, "the river Nile."

The course of the Nile has already been noticed in speaking of the form of the Nile valley. In ancient times the Delta was watered by seven branches; now there are but two, the other ancient branches being canals not always navigable. The ancient branches were, beginning at the west, the Canobic, Bolbitine, Sebennytic, Pathmitic, Mendesian, Tamtic, and Pelusiac, of which the modern Rosetta and Damietta branches represent the Bolbitine and Pathmitic.

The mean breadth of the river in Upper Egypt may be put at from half a mile to three-quarters, except where large islands increase the distance. In the Delta the branches are generally narrower.

A remarkable change has been ascertained to have occurred in the level of the Nile above Gebel-es-Silsileh, (near the ancient Silsilis, more than 80 miles south of Thebes), and throughout part of Nubia. Indications of this change were first observed by Professor Lepsius, who discovered hieroglyphic inscriptions on rocks at the Cataract of Semneh, not far above the Second Cataract, showing that the river attained a much higher level in the time of Dynasties XII. and XIII. before B.C. 2000. He gives the difference of the mean water-level at Semneh as 7·30 metres, or 23·94 feet English. He observes that the whole level of Upper Nubia was anciently greater, and similarly that of Lower Nubia between the First and Second Cataracts, but that in this second tract the present level was attained since the time of Thothmes III. of Dynasty XVIII. (*Auszug aus einem Schreiben des Hrn. Lepsius an Hrn. Ehrenberg*, Phila., 10th Sept. 1844.) Sir Gardner Wilkinson pursued the inquiry in a paper in which he argued that the cause of the change of level which he traced in the Upper Thebais was the breaking of a rocky barrier at Gebel-es-Silsileh, where the low mountains on either side confine the river to a narrow channel (*Trans. R. Soc. Lit.*, u.s., iv.).

The water of the Nile differs considerably in appearance and purity at various seasons of the year. A little after midsummer it becomes very turbid, and not long afterwards

¹ The manner in which this term is used (Num. xxxiv. 5, Josh. xv. 4, 47; 1 K. viii. 65; 2 K. xiv. 7; Is. xxvii. 12), to designate the boundary of Egypt and Palestine, precisely as Shichôr is employed (Josh. xiii. 3; 1 Chr. xii. 5), would be conclusive as to their identity, were it not that the country between the Pelusiac branch and Rhinocorura is a waste region, which may have been wholly considered as boundary.

² "En-Neel is the river (lit. the inundation) of Egypt: Es-Saghânee says—'But as to the neel [indigo] with which one dyes, it is an Indian word Arabicized'" (*The Misbâh of El-Feiqomee*)

it assumes a green colour for more than a fortnight, owing to the quantity of vegetable matter which it brings down from its upper course. It then resumes its turbid character for the period of the rise, and retains it, though in a less degree, for the remaining portion of the year, until the following midsummer. The water is extremely sweet, particularly in its turbid state. A careful filtration destroys its peculiar flavour, and the best method is to allow it to settle in the porous jars manufactured in the country. It is very wholesome, except during the short period at which it is green. The turbid appearance, greatest during the rise and inundation, is owing to the presence of large quantities of earthy matter, which are annually deposited. This deposit or mud of the Nile has been analyzed by M. Regnault. The specimen was dry, and taken from a canal which conducted the waters of the inundation. He obtained the following results:—

Water..	11
Carbon	09
Oxide of iron	06
Silica	04
Carbonate of magnesia..	04
Carbonate of lime..	18
Alumen	48

M. Regnault remarks that the quantities of silica and alumen vary according to the places whence the mud is taken, and that on the banks of the Nile it contains much sand, but when carried by the waters of the inundation to distant tracts it loses a quantity of sand in proportion to the distance, so that, when the distance is very considerable, the argillaceous matter is nearly pure; and thus the soil presents this matter in the different degrees of purity which the arts of pottery and brick-making require (*Descr. de l'Égypte*, xx. 162–164).

The Nile shows the first signs of rising in Egypt about the time of the summer solstice. At Khartoom, where the White and Blue Niles join, the beginning of the increase is observed early in April (Clot-Bey, *Aperçu*, i. p. 36, 37). The slowness of the rise in the earlier stage causes this difference. Usually the regular increase does not begin in Egypt until some days after the summer solstice, and the inundation begins about two months after that solstice. The river attains its greatest height at, or not long after, the autumnal equinox, and then, falling more slowly than it had risen, sinks to its lowest point at the end of nine months, when it remains stationary for a few days, until it begins again to increase. The inundation continues rather longer than it naturally would do, because the waters are retained for some time upon the lands by closing the mouths of the canals (see the table, *Descr. de l'Égypte*, xviii. i. 630, *seqq.*, for the details of the state of the Nile, from July 2, 1799, to April 10, 1800). The river's banks being a little higher than the rest of the cultivable soil, the water is conveyed by canals or cuttings, and does not pour over the banks.

The inundations vary considerably, and, by either failing or rising to too great a height, cause much damage and distress. In the *Description de l'Égypte* (xviii. i. 626–629) there is a table of 66 inundations, of which 11 were very high, 30 good, 16 feeble, and 9 insufficient. This table was taken from the official records of the Nilometer on the island of Er-Ródah, near Cairo, and comprehends the inundations of A.H. 1150–1215 (A.D. 1737–1800).

The Nile rises about 40 feet at the First Cataract, about 36 at Thebes, about 25 at Cairo, and about 4 at the Rosetta and Damietta mouths during a good inundation (*Englishwoman in Egypt*, i. 89, *Descr. de l'Égypte*, xviii. i. 576, 577). When it is said, however, that the river has attained to a certain height in feet or cubits, the height at the Nilometer of Er-Ródah above-mentioned is meant; and

by ancient writers, that of the river at Memphis, which was situate on the western bank, a little higher than Er-Ródah. If the river do not attain a greater height than 18 or 20 feet, the rise is scanty; if only 2 or 4 feet more, insufficient; if it attain to 24 feet, or a greater height, not exceeding 27 feet, the inundation is good; but a higher rise must be characterized as a destructive flood (*Descr. de l'Égypte*, xviii. i. 616). Sometimes the inundation has failed altogether; as for seven years (A.H. 457–464) in the reign of the Fátimée caliph El-Minstansir bi-lláh, when there was a seven-years' famine (see below, page 752); and low inundations always cause dearths. Excessive inundations, on the other hand, produce, or at least foster, the plague and murrain; so that a variation of a few feet is productive of the most serious consequences.

The current, when the Nile is low, has been estimated at about 2 miles in the hour, and at about 3 miles an hour when it is high. The volume of water which the Nile pours into the Mediterranean in 24 hours is as follows, according to M. Linant:—

		Cubic Metres.
During the low Nile,	{ by the Rosetta Branch,	79,532,551,728
	{ by the Damietta Branch,	71,033,840,640
		150,566,392,368
During the high Nile.	{ by the Rosetta Branch,	478,317,838,960
	{ by the Damietta Branch,	227,196,828,480
		705,514,667,440

—(Clot-Bey, *Aperçu*, i. 41).

Although the water is abundantly charged with alluvium throughout the year, and especially during the inundation, the annual deposit by the river, except under extraordinary circumstances, is very much smaller than might be supposed. Various computations have been made as to the exact deposit left in a century on the land, but they have not usually differed above an inch. If, however, we compare the quantity of deposit on certain very ancient structures, of which we know the date, we shall find that the amount has materially differed in various places. Such differences are the natural results of irregularities in the river's course, of the strength or weakness of the current at particular places, of the nature of the country, and many other disturbing causes. The mean ordinary rate of the increase of the soil of Egypt has been calculated by Mr Lane as about $4\frac{1}{2}$ inches in a century. M. Girard, in the *Descr. de l'Égypte*, makes it "very nearly" 126 millimètres, or 4.960 English inches (For a remarkable instance of rapid deposit, see the *Englishwoman in Egypt*, i. 132–134, and plan, p. 126.)

The cultivable land of Egypt must be regarded as wholly the deposit of the Nile, but it is vain to attempt a calculation of the period at which this process began, since we cannot conclude that the same rate has always obtained, and we must suppose that the causes at first in operation were very different from those which now regulate the phenomenon.

At the time of the French occupation of Egypt it was found that the cultivable soil occupied only 6921 square miles, or somewhat more than two-thirds of the whole space included between the deserts; but the quantity actually under cultivation did not exceed 5500 square miles, or six-elevenths of the entire surface. This proportion has since not materially changed. It was not always so, and the deficiency of the population is the principal cause that so large a proportion of the soil which might possibly be brought into a state of culture is left uncultivated.

Throughout Egypt the cultivable soil does not present any very great difference, being always the deposit of the river; it contains, however, more sand near the river than at a distance from it. Towards the Mediterranean, its

quality is injured by the salt with which the air is impregnated, and therefore it is not so favourable to vegetation. This condition, however, is not usually found far south of the sea, or the salt-marshes and lakes, which intervene for the most part between it and the land. In Lower Egypt we find the greater portion of the neglected tracts principally to the east and west of the modern Delta, and in its northern portion. In Upper Egypt the narrowness of the valley, and the more numerous population, preserve the country in a better state of cultivation, and the soil is somewhat richer. The largest uncultivated tracts lie on the western bank, where the valley is broadest, and in places where the great canal running parallel to the Nile has fallen into a state of neglect.

Condition of the Country.—Although some of the accounts of the classics may be deemed exaggerated when they speak of the population and prosperity of Egypt, we cannot accuse them of errors, except in the number of towns and of the inhabitants of the country, for the monuments show us how rich was Egypt under native rulers, and indicate to what causes this condition may reasonably be assigned. From the time at which the Great Pyramid was built to the Persian invasion, a period of between 2000 and 3000 years, the population of Egypt and its extent of cultivated land far exceeded what they are in the present day. The country does not seem to have been over-peopled; and many causes conduced to prevent this, particularly the serious wars in which the Pharaohs engaged. The long and desolating struggles with the Assyrians and Persians inflicted a severe blow on the interests of the country. Under the Macedonians it recovered much of its former prosperity; and when the Romans held Egypt, it was one of their most productive provinces, and a granary of the empire. During the Roman rule various political causes contributed to the decline of the population. After the Muslim conquest this decay continued almost uninterruptedly until the time of the Fâtimites, but from that time until the Turkish conquest the rulers of the successive independent dynasties generally governed the country with a regard for its interests, and cannot be accused of the systematic tyranny and misrule of the Turkish pashas. There was a temporary recovery under the independent or semi-independent Memlook rulers before the French invasion; and in spite of much of the Turkish system the country has again made good progress during the government of the family of Mohomet Ali. To over-taxation, forced labour, and needless wars,—in other words, government in a Turkish sense,—must be attributed the present misery of the peasant population, and the want of hands enough to cultivate the soil.

Physical causes have had far less to do with the impoverishment of Egypt than political ones. The elevation of the tract north of the Gulf of Suez, with the depression of the north coast of Egypt, has much diminished the cultivable soil in the Delta, by increasing the salt lakes and marshes which occupy its northern portion. There is, however, no greater fallacy than to suppose that the sands of the deserts have done injury by encroaching upon the alluvial tracts, and that once fertile regions are buried beneath them. In some places undoubtedly they have encroached upon the cultivable land, particularly where, as in the case of the canal of the Red Sea, the neglect of the Government had withdrawn the inundation, but no sooner was the Sweet Water Canal opened than fertility returned. On the other hand the deposit of the Nile has been constantly, in almost every part of the country, encroaching upon the deserts and diminishing their extent. It is neglect that has permitted the sand to drift over the soil where there have been no labourers to cultivate it. Above Gebel-es-Silsileh, in Upper Egypt, the change in the level of the river has placed cul-

tivable soil almost wholly beyond the reach of the inundation, and thus made agriculture very laborious, but this is only for the space of about 40 miles in Egypt, where the extent of the cultivable soil must always have been small on account of the narrowness of the valley. The failure of five of the seven branches of the Nile is partly due to the neglect of the Government, as they might all have been retained as constantly running canals; and the decay of the great canal which runs parallel to the Nile throughout the chief part of Upper Egypt is traceable to the same cause.

Under the government of Mohomet Ali a great engineering work was begun with the view of bettering the condition of Egypt. This was the construction of a barrage across both branches of the Nile at the point of the Delta, in order to regulate the inundation, and thus render the country more fertile and easy of cultivation. After being abandoned this work is now to be completed. Its operation will on the whole be beneficial, although undoubtedly the power to be thus acquired by the khedive, of regulating the inundation for the benefit of his lands without reference to small proprietors, will be productive of much injustice. Egypt can never regain her ancient prosperity without a radical reform. The country has been governed under the Turks upon the system of getting the maximum of revenue from a peasantry allowed the minimum of sustenance. This is what is meant by the high-flown phrases one hears about the welfare of Egypt. The welfare of the population has never been contemplated. The frugal peasantry are kept at starvation-point, and no one prospers but the tax-gatherers of all grades, who constitute the richer class. Yet Egypt is better governed than the other provinces of the Turkish empire which enjoy a purely Turkish administration, for it is held not on the uncertain tenure of an ordinary pashalik, but as a copyhold which it is the interest of the tenant to keep in decent repair.

Agriculture.—Under the Pharaohs Egypt was an agricultural country, and both commerce and manufactures were comparatively unimportant. The main energies of the people were expended in turning to the best account a soil of unexcelled richness, annually watered and renewed by the river. This natural policy was the true one for the prosperity of the country. From the sculptures and paintings of the tombs, we form a clear idea of the agriculture of the ancient Egyptians, while the classical writers give us information respecting the tenure of land, and the laws affecting the cultivators.

In the representations of the tombs which picture the daily life of the great proprietors of land, we learn what especial attention they paid to the processes of agriculture. We see them constantly overseeing the labourers, and thus watching the interests of their lands. They were especially anxious to conduct the water of the Nile over those tracts which were not above its level at different periods of the year, and to raise it by manual labour to the higher portions of the land. In their canal-system they displayed mechanical skill, as well as in the construction of dams and dikes to retain the water upon the lands; but for raising water they seem to have been contented with the rudest contrivances. Indeed we know of but two methods that were employed in raising water,—the use of the simple machine called in the present day the shadoof, and buckets carried by men. The ordinary shadoof still employed is of the same form as that used by the ancient Egyptians. It consists of a pole resting upon a beam placed across two columns of brick or mud, and having at one extremity a weight, and at the other a rude bowl-shaped bucket suspended by a stick. A man stands beneath it, and pulling down the bucket to the water raises it again, assisted by the weight. (For the ancient form of the shadoof, see *Anc. Eg.*, ii. 4; for the modern, *Mod. Eg.*, chap. xiv.)

Immediately after the water of the inundation had subsided, the land was ploughed or broken up by the hoe, and sown, the seed being sometimes trodden in by goats driven over the field for the purpose. Wheat being the most important field-produce, we find the various agricultural processes connected with it frequently represented. Besides the ploughing and sowing, the harvest is depicted, the reapers cutting the wheat just below the ear, the ears being carried in nets or baskets by men or on asses to the thrashing-floor, where they were thrashed by kine. Sometimes the wheat was bound in sheaves. The same or similar processes with reference to other kinds of grain are portrayed in the tombs, in which we also find curious representations of the vineyards and gardens. The vineyard was not the least valuable part of an estate. Egypt was famous for its wines in the days of the Greeks and Romans; and it is evident that wine must have been prized in earlier times from several kinds being enumerated in the inscriptions, and from its always being seen at the feasts. Besides the vine, other fruit-trees were cultivated, and especially the date-palm. The gardens were often extensive, and were laid out with great formality, partly in consequence of their being watered in the same manner as the fields generally, and contained tanks for fish as well as for purposes of inundation. The Egyptians paid great attention to preserving fish, and the produce of the fisheries of one great artificial lake, that of Mœris, formed an important branch of the revenue. There were also tracts left to reeds, which, if not planted, were at least carefully maintained, on account of their value for manufactures, and as covers for wild-fowl.

Diodorus Siculus states that anciently the land was the property of the priests, of the king, and of the military class (l. 73), and the monuments leave little room to doubt that such was generally the case, for though there were no estates, the upper classes consisted of priests and military officers, and the son usually followed his father's profession. It is stated in the Bible that Joseph purchased the whole of the land of the Egyptians for food during the famine, and gave them seed to sow it, claiming a fifth of the produce as the king's right. The land of the priests alone was not purchased.

The agriculture of the modern Egyptians differs little from that of the old inhabitants. In one respect it is the converse: the ancients excelled in the management of dikes and dams, and raised water only by the simplest methods; the moderns, while they have paid less attention to the great canals, and the means by which they were regulated, have employed more ingenious methods of artificial irrigation. The deficiency of population has partly caused the decay of many of the canals and dams and dikes, and has at the same time necessitated the economizing of human labour, for which that of cattle has been in a great measure substituted.

Of the machines the most common is the shâdoof, already described, but there are also two kinds of water-wheels. The more usual of these is that called the sâkiyeh, which is composed of a horizontal wheel turned by a pair of cows or bulls, or by one, and connected with a vertical wheel which is on the same axis as another around which are earthen pots in which the water is raised and poured into a trough. The tâboot is a similar machine, which differs from the sâkiyeh principally in having a hollow wheel instead of the wheel with pots, in the jannts or fellics of which the water is conveyed. Sometimes a katweh is employed, which is a bucket like that of the shâdoof, having four cords by which two men dip it into the river or canal and raise the water. (*Mod. Eg.*, ch. xiv.) Steam-pumps are now largely used.

"The 'rei' lands (or those which are naturally inundated) are, with some exceptions, cultivated but once during the year. After the waters have retired, about the end of October or beginning of

November, they are sown with wheat, barley, lentils, beans, lupins, chick-peas, &c. This is called the 'shutawee' (or winter) season. But the 'sharâlee' lands (or those which are too high to be subject to the natural inundation), and some parts of the rei, by artificial irrigation are made to produce three crops every year; though not all the sharâlee lands are thus cultivated. The lands artificially irrigated produce, first, their shutawee crops, being sown at the same period as the rei lands, generally with wheat or barley. Secondly, in what is called the 'esfyee,' or in the southern part of Egypt the 'keydee' or 'gyzyee' (that is, the summer) season, commencing about the vernal equinox, or a little later, they are sown with millet ('durah esfyee'), or with indigo or cotton, &c. Thirdly, in the 'demereeh' season, or period of the rise of the Nile, commencing about or soon after the summer solstice, they are sown with millet again, or with maize ('durah shimee'), &c., and they are crowned with a third harvest. Sugar is cultivated throughout a large portion of Upper Egypt, and rice in the low lands near the Mediterranean."—*Mod. Eg.*, l. c.

The culture of cotton was introduced by Mehemet Ali with a view to promote his manufacturing schemes, and the Turkish grandees have found it a source of temporary profit. During the American War the profit was at its height, but subsequently it declined. The necessity of constructing dams to exclude the Nile water from the cotton-growing fields has rendered the inundations destructive, and the speculation seems on the whole to have injured the welfare of Egypt.

The agricultural implements of the modern Egyptians are rude in construction, and similar to those anciently employed in the country. One of these, however, was not known to the earlier inhabitants. This is the nôrag, a machine "in the form of a chair, which moves upon small iron wheels or thin circular plates, generally eleven, fixed to three thick axle-trees, four to the foremost, the same number to the hindmost, and three to the intermediate axle tree. This machine is drawn in a circle by a pair of cows or bulls over the corn." It is employed to separate the grain of wheat, barley, &c., and to cut the straw, which is used for fodder. (*Mod. Eg.*, l. c.) The ancient Egyptians, as before remarked, generally cut the wheat near the ear.

An Egyptian garden is a miniature Egypt. It is intersected by numerous small channels which are filled by one or more water-wheels. By these channels the water is spread over the garden, divided by them into many square compartments, edged with ridges of earth. This system of course makes it very difficult to keep a garden in good order, and no great variety of flowers is cultivated.

Though Mehemet Ali was very desirous to encourage manufactures, he did not endeavour enough to apply modern science to the improvement of agriculture. Ibrahim Pasha, who succeeded him, always maintained that the country should be agricultural rather than manufacturing, and introduced important improvements during his father's government. This system has been steadily pursued by the present ruler.

Before the time of Mehemet Ali a kind of feudal system prevailed, and much of the land was held by small proprietors under the protection of the great emeers. By the massacre of the Menilooks, the pasha destroyed feudalism, and by arbitrarily seizing almost all the landed property, rendered private tenure of land a most rare condition. He allotted to those whom he thus unjustly dispossessed annual pensions for life, as the only compensation for an act of tyranny to which even the history of Egypt scarcely affords a parallel (*Mod. Eg.*, ch. iv.). Those whose lands were not confiscated yielded them up through fear, and buried their title-deeds, which are yet so concealed. A system of government in which the supreme authority overlooks such acts, and subordinate governors perpetrate them, in defiance of the Muslim code and Arab jurisprudence, demands the most thorough and searching reform.

Lakes.—Egypt has always been famous for its lakes,

which have either aided commerce, or supplied the inhabitants of the country with fish and wild fowl, or with valuable vegetable productions, or assisted in regulating the effects of the inundation. All have enriched the land in some one of these ways, and thus they have been important sources of its natural wealth.

Beginning our examination at the north-western extremity of Egypt, we first observe the lake now called Boheyret-Maryoot,¹ and anciently Lake Mareotis. This is an extensive salt marsh rather than a lake, except during the inundation, when its contents are augmented by filtration. Anciently this lake was navigable, and thus contributed to the commercial importance of Alexandria. The country around was cultivated, and produced the famous Mareotic wine. The relations of various travellers show that it was still a lake during the 15th and 16th, and even towards the close of the 17th century; and Villamont in 1590 mentions that in his time the fisheries produced a considerable sum (*Descr. de l'Égypte*, xvi. 201). When, however, the French army conquered and occupied Egypt (1798-1801) they found its basin to be "a sandy plain, of which the lower portion retained the rain-water, which remained there for a great part of winter" (*Id.* 200, 201). On the 1th of April 1801 the English army, which was co-operating with that of the Grand Vizir against the French garrison of Alexandria, cut the dikes of the canal of that city, and admitted the waters of the Lake of Aboo-Keer into the ancient bed of Lake Mareotis, in order to cut off the water supply of the besieged (*Id.* 201, 202). The basin of the lake being partially inhabited, some loss of life and property was the result of this act, which has reasonably been much called in question. The unhealthiness of Alexandria is also traceable to the formation of this marsh. The precedent thus set has been twice imitated, first by the Turks in 1803, and a second time by the English army under General Fraser in 1807. At the present day the lake or marsh is unprofitable, and its shores are uncultivated and uninhabited, the whole wearing the most dreary aspect.

To the north of Lake Mareotis is situate that of Aboo-Keer, Boheyret-Aboo-Keer. It is the northernmost portion of the other lake, from which it is separated by the Mahmoodeech Canal (which here occupies the line of the older Canal of Alexandria), and the embankments or dikes which form its banks. It is very small, nowhere measuring 10 miles across, and extremely shallow, usually not exceeding 3 feet in depth. The water is salt, being chiefly derived from the sea, from which the lake is separated by a narrow strip of land on the western side, and on the eastern by a similar strip of far less breadth, the shore of the memorable Bay of Aboo-Keer.

To the east of the Lake of Aboo-Keer is that of Atkoo, Boheyret-Atkoo. It spreads when full nearly to the town of Rosetta, and is separated from the sea by a narrow neck of land on which stands the large village of Atkoo. Its extent varies according to the quantity of water which it receives from the inundation (*Descr. de l'Égypte*, xvi. 204).

The great Lake of El-Burullus begins a little to the eastward of the Rosetta Branch, and stretches to somewhat beyond where the canal which was anciently the Sebennytic Branch enters it, and passing through it reaches the sea. Like the other northern lakes, it is separated from the Mediterranean by a narrow strip of land, the coast of Egypt. It is throughout very shallow (*Id.* 205). It is chiefly known for its water-melons, which are

yellow within instead of being red or pink, and come into season after those grown on the banks of the Nile.

The easternmost of the lakes of Egypt is Boheyret-el-Menzeleh, which greatly exceeds the others in size. It extends from very near the Damietta Branch of the Nile to the mouth of the old Tautie Branch, now called the canal of El-Mo'izz, which passes through the lake to the sea. It also receives the waters of the canals which were once the Mendesian and Pelusiac Branches. The northern shore is separated from the sea by an extremely narrow strip of land. At its south-eastern extremity is a long marshy creek extending into the desert. Its average length is about 40 miles, and its average breadth about 15. The depth is greater than that of the other lakes, and the water is salt, though mixed with fresh. Upon the surface are numerous islands, and the whole lake abounds in reeds of various kinds. It supports a considerable population of rude fishermen, who dwell in villages on the shore and islands, and live upon the fish of the lake. The reeds are cover for water-fowl of various kinds, which the traveller sees in great numbers, and wild boars are found in the marshes to the south. (*Mod. Eg. and Thebes*, i. 446)

The Lake Serbonis, well known in former times as having swallowed up those passing over its marshes concealed by shifting sands, is now dry, and cannot be any longer included in the list of the lakes of Egypt.

Besides the lakes above mentioned are those called the Bitter Lakes, which should rather be termed marshes, occupying part of the ancient bed of the Red Sea between Suez and Lake Menzeleh, and also the Natron Lakes. The latter, which are very small, are situate in a valley of the western desert, not very far from the river. they will be noticed below.

In Upper Egypt there is but one lake of importance. It is the Buket-el-Karn, or Lake of El-Karn, at the extremity of the Feiyoom, which is, as already mentioned, an oasis on the western side of the river, to which an opening in the mountains leads. The lake is about 35 miles long, and its widest part a little exceeds 7 miles, according to Sir Gardner Wilkinson, while in several places it is considerably narrower. About the middle is a single island. The depth is not great, for the same author, who "sounded in several places," "found what is considered the deepest part to be only 28½ feet" (*Mod. Egypt and Thebes*, ii. 344-5). Its level is far below that of the Nile, as the bank of the river at Benec-Suwey, at the entrance of the valley leading to the Feiyoom, is upwards of a hundred feet higher than the water of the lake (*Ibid.* 346). The shores are barren or uncultivated, the northern is desert and bounded by sandy mountains, the southern was in ancient times partly cultivated. The water is brackish and unwholesome, though the fishermen, of whom there are a few, drink it.

The famous Lake Moeris lay between the Feiyoom and the Nile, not far from the river. It was an artificial work executed by Amenemhat III., of Dynasty XII. The irrigation of neighbouring tracts was regulated by it, and its fisheries formed an important part of the revenue. After the subjugation of Egypt by the Romans its dikes were neglected, and by degrees it became ruined. Its position and extent were considered doubtful, until M. Luvant's excellent memoir, published by the Egyptian Society of Cairo, established these points most satisfactorily from the remains of its basin, which are yet traceable (*Mémoire sur le Lac Moëris*, Soc. Eg., 1843).

Canals.—The canals of Egypt deserve especial attention from their great importance in extending the beneficial influence of the inundation. In Lower Egypt we find, beginning from the west, first the Mahmoodeech Canal, which connects Alexandria with the Rosetta Branch, taking

¹ "Boheyreh," (pronounced "Boheyret" when followed by a genitive) signifies "a little sea," being the diminutive of "bahr," "a sea," and is applied to large lakes, smaller ones receiving the appellation "birket." The distinction is not always maintained, for the great lake of the Feiyoom is called Birket-el-Karn.

a similar direction to that of the ancient canal which it has succeeded. It was dug under Mchemet Ali; and although not quite 50 miles in length, and not 100 feet broad, about 12,000 labourers are said to have died in ten months while the work was in progress (*Englishwoman in Egypt*, i. 47, 48). This is well known to be a tolerably accurate statement of the losses experienced by the unfortunate workmen, and is only one of the many instances which the history of our own times affords of that reckless disregard of human life, which is one of the worst traits of Turkish character.¹

Between the Rosetta and Damietta Branches are several canals, some of which are of importance, particularly the short canal of Mauoof connecting the two branches not far from the point of the Delta. To the east of the Damietta Branch are others, of which the most remarkable occupy the beds of the Tanitic and Pelusiatic Branches, which have been cleared to a sufficient extent to form canals. The former of these, which lies to the westward of the other, is called the Canal of El-Mu'izz, the first Fátimée caliph who ruled in Egypt, having been dug by his orders, and the latter bears the name of the Canal of Abu-l-Munegga, a Jew who executed this work, under the caliph El-Amir, in order to water the province called the Sharkeeyeh. The last mentioned canal is connected with the remains of that which anciently joined the Nile and the Red Sea. Of this important work the greater part was destroyed through neglect, but it has been restored, as the Sweet Water Canal, in order to supply the establishments on the Suez Canal with fresh water. It was of the Pharaonic times, having been begun by Ramses II., or Sesostris, continued by Neku II. and by Darius Hystaspis, and at length finished by Ptolemy Philadelphus.

The extent and character of the great canal called the Bahr-Yoosuf, or River of Joseph, which runs parallel with the Nile on its western side, from a little below Cairo to near Farshoot, a distance by the river of about 350 miles, render it the most important work of the kind in Egypt. It is a continuous series of canals rather than one canal. Although the Joseph whence it takes its name is the celebrated Saladin, or Salâh-ed-deen, yet it is related that he merely repaired it, and it is not doubted to be of a much earlier period. Most probably it was executed under the Pharaohs. In the present day it is not navigable except during the season of the inundation, and at other times is dry in various places. Its restoration would not be a work of extreme difficulty, and would greatly benefit the commerce and agriculture of the country, perhaps more than any other undertaking of the kind.

¹ A note from the eighth edition of this work is here reprinted in substance.—Writers on the East have not generally been careful to distinguish the Turkish and Arab national character, and the former has thus had the advantage of the virtues of the latter, which has received in return the odium of the other's vices. The remarkable characteristics of Arab character are high honour, generous hospitality, and humanity, coupled with much deceit in small matters not considered points of honour, carelessness as to religion, though not irreligion, and a love of plunder. The Turkish character is as strongly marked by treachery, often of the blackest kind, little hospitality, particularly to strangers, cruelty and disregard of human life, bigotry as to their religion, which is now giving way to deism, and the same love of plunder which is so common among the Arabs, as well as darker vices unknown to them, which have rendered the Turkish name a by-word in the East, as well as in the West. The conquests of the Arabs were not marked by desolation; their rule preserved the philosophy of Greece, which was welcome at the court of Baghdad when unknown in Europe. Arab art was due to them, and though long maintained under Turkish rule, at last perished through it. The rule of the Turks is traced by ruined cities, and whole provinces laid waste; literature has forsaken its most famous seats, Constantinople, Athens, Alexandria, and Antioch, the arts have decayed. Until they held Egypt and Mesopotamia, these were the richest countries of the world, now they are half deserts. All these are facts which can be proved.

Vegetable Products.—Egypt differs from most other countries in having neither woods nor forests. Besides the palm groves, we rarely see even a grove of trees, except in Lower Egypt. The largest common trees are acacias, sycamore-fig-trees, and mulberry-trees, all of which are frequently planted on each side of the great roads near Cairo; and the most beautiful trees are the date-palm and the banana. The beauty of the palm is, however, in a great measure owing to art, for its lowest branches are annually cut, which causes it to grow high, and renders its head of elegant form. When wild, this tree has a far inferior appearance, being low, and having long ragged branches reaching to the ground; and its dates are small and poor in flavour. The Theban or dôm-palm is a very different tree, having two great branches, each of which divides into two other branches, a subdivision which continues still farther. The weeping-willow, myrtle, elm, and cypress are found in the gardens and plantations, with various trees bearing the fruits to be next mentioned; and the tamarisk is to be seen everywhere.

The most common of the fruits are dates of various kinds, which are sold half-ripe, ripe, dried, and pressed in their fresh moist state in mats or skins. Many different sorts are enumerated as known in Egypt. The dependencies, however, and not Egypt, produce the finest of these dates. The hotter and drier climates of the Oases and Lower Nubia best suit the date-palm; and the pressed dates of Secwah, the ancient Oasis of Jupiter Ammon, are among the most esteemed. The grape is a common fruit, but wine is not made from it on account of the prohibition of Mohammad. The Feiyoom is celebrated for its grapes, and chiefly supplies the market of Cairo. The most common grape is white, of which there is a small kind far superior to the ordinary sort. The black grapes are large, but comparatively tasteless. The vines are trailed on trelliswork, and form agreeable avenues in the gardens of Cairo; but little attention is paid to their culture, the common fault of Egyptian agriculture and gardening, due to the generosity of nature and the indolence of the inhabitants.

The best known fruits, besides dates and grapes, are figs, sycamore-figs, and pomegranates, apricots and peaches, oranges and citrons, lemons and limes, bananas, which are believed to be of the fruits of Paradise (being always in season), different kinds of melons (including some of aromatic flavour, and the refreshing water-melon), mulberries, Indian figs or prickly pears, the fruit of the lotus, and olives. Many of these are excellent, especially the figs and melons. The trees and plants which produce most of them are chiefly confined to the gardens. The cactus bearing the Indian fig is extremely common, and forms the hedges of gardens and plantations.

The general plan of an Egyptian garden has been already described. Although seldom in good order, such a garden is often picturesque, having a few date-palms and bananas, and perhaps overlooked by one of those houses of the old style of architecture which are rapidly disappearing. No great variety of flowers is cultivated. Among the more usual are the rose (which has ever been a favourite among the Arabs), the jasmine, narcissus, lily, olcander, chrysanthemum, convolvulus, geranium, dahlia, basil, the henné plant (*Lawsonia alba*, or Egyptian privet, which is said to be a flower of Paradise), the helianthus, and the violet.

The vegetables, &c., are very common and of various kinds, so that we cannot wonder that the Children of Israel longed for them in the desert. The principal are beans, pease, vetches, lentils (of which a pottage is made, which is the common food of the Nile boatmen), lupins, chick-pease, the loobyeh (*Dolichos lubia*), fenugreek, mallows, the bamiyeh (*Hibiscus esculentus*), spinach, purslain,

melookhceyeh (*Corchorus olitorius*), leeks, onions, garlic, celery, parsley, chicory, cress, radishes, carrots, turnips, colocasia, lettuce, cabbage, fennel, gourds and cucumbers (both of several kinds), the tomato, the egg-fruit or badingán (black and white), caraway, coriander, cumin, aniseed, and red pepper.

The chief field-produce is wheat (which is more grown than any other kind of corn), barley, several sorts of millet, maize, rice, oats, clover, pease, the sugar-cane, roses, two species of the tobacco-plant, and cotton, now largely cultivated. The sugar-cane is extensively cultivated, and excellent sugar is manufactured from it. There are fields of roses in the Feiyoom, which supply the market with rose-water. The tobacco produced in Egypt is coarse and strong compared with that which is used by the middle and upper classes and imported from Syria and Turkey. That of Syria is considered the best. Of textile plants, the principal are hemp, cotton, and flax; and of plants used for dyeing, bastard saffron, madder, woad, and the indigo plant. The intoxicating hasheesh, which some smoke in a kind of water-pipe formed of a cocon-ut, two tubes, and a bowl, seldom used for any other narcotic, is not, as has been erroneously supposed, opium, but hemp. The effect is most baneful. The leaves of the henné plant are used to impart a bright red colour to the palms of the hands, the soles of the feet, and the nails of both hands and feet, of women and children, the hair of old ladies, and the tails of horses. Indigo is very extensively employed to dye the shirts of the natives of the poorer classes, and is, when very dark, the colour of mourning; therefore, women at funerals, and generally after a death, smear themselves with it. Oil is extracted from the seeds of the cotton plant, hemp, colowort, the poppy, the castor-oil plant, sesame, and flax. The high coarse grass called halfch (*Poa cynosuroides*) grows in great quantity in waste places and among ancient ruins.

Many kinds of reeds are found in Egypt, though, if we compare the representations in the ancient tombs with what we see in the present day, it is evident that they were formerly much more common. That they should be wasted away was prophesied by Isaiah (xix. 6, 7). The famous byblus, or papyrus, from which paper was manufactured, appears to be nearly, if not quite extinct, since Sir Gardner Wilkinson had never seen it (*Mod. Eg. and Thebes*, i. 441). M. Delile, in his excellent account of the Egyptian flora, merely mentions it by name in his list as the *Cyperus Papyrus*, called in Arabic *berdy*, and found at Damietta,¹ but gives no figure of it. The lotus, greatly prized for its flowers by the ancient inhabitants, is still found in Egypt, though it is not common. The French naturalist above mentioned enumerates three species which formerly grew in that country, one with white flowers, another with blue, and a third with rose-coloured, the last of which is now extinct there. On the botany of Egypt, see Boissier, *Flora Orientalis*, in progress.

Animals.—The zoology of Egypt is not of remarkable interest, although it contains some very curious points. The absence of jungle and of forest, and the little cover thus afforded to beasts of prey, as well as other wild animals, partly causes this; and we observe few birds of beautiful plumage for the same reason.

One of the most characteristic of the beasts is the camel, which is more at home in the dry climate of Egypt than elsewhere out of his native deserts. It has been remarked, however, that the camel, like his master the Arab,

degenerates when removed into a city or a cultivated tract, that the former commonly becomes mangy, and the latter experiences a physical and moral degradation. The Egyptian camel is of the one-humped kind, which has been erroneously called the dromedary, whereas the dromedary is merely a swift camel standing in the same relation to the ordinary camel that our saddle-horse does to our cart-horse. Camel's flesh is for the most part eaten only by the peasants and the Arabs of the desert; by the Copts it is considered unlawful food.

It is very remarkable that no representation of the camel has been found in the sculptures and paintings of the Egyptian monuments, among the very numerous figures of the animals of Egypt both tame and wild, and of those brought from foreign lands as presents. It does not appear to have been introduced into other African countries until after the Christian Era (comp. Desmoulins, *Mém. lu à l'Institut*, 28 Juin 1823); but it was known to the Egyptians, although it is by no means certain that it was one of their domestic beasts. Two passages in the Bible which speak of camels in the possession of Pharaohs (Gen. xii. 16; Ex. ix. 3) refer to the time at which foreign tribes had been settled in Egypt; and perhaps the camel was peculiarly the animal of one or all of those tribes, and, as they were hated by the Egyptians, it may have been omitted in the representations of the monuments.

To modern Egypt the camel is very valuable, since the traffic with Syria, Arabia, Western Africa, and Ethiopia is to a great extent carried on by caravans. But the ancient Egyptians appear to have derived their wealth more from tributary presents than from commerce, to have allowed their land commerce to be much in the hands of foreign merchants, like those who brought Joseph into Egypt, and to have left even their sea commerce partly at least to foreigners.

The horse is not known to have been used in Egypt before the time of the Empire. Thenceforward the horses of Egypt were famous, and the armies of the Pharaohs were noted for their war-chariots. From Egypt, Solomon, and in his time the kings of the Hittites and the kings of Syria, had horses and chariots (1 K. x. 28, 29). And long after, when first the kingdom of Israel and then that of Judah endeavoured to throw off the yoke of the great kings of the East, and made alliance with Egypt, they put their trust in Pharaoh's horses (Isa. xxxi. 1). In the representations of battles fought by the kings of the Empire we see no Egyptian cavalry, but only chariots, called "horse" in the inscriptions. At later times they may have had cavalry, properly speaking, of their own, and perhaps at all times among the mercenary or auxiliary forces.

In the present day the horses of Egypt are of a very indifferent breed, and the best that one sees in that country have been brought from Arabia and Syria, but these are seldom of great excellence. It is indeed surprising to find few really good horses in a country bordering on Arabia, and not many years ago this was still more remarkable, though not during the existence of the Memlooks. The finest Arabs, however, are kept in the background by their possessors, partly for fear of the "evil eye," and partly, in the case of all but the highest dignitaries, to avoid their forcible seizure by those of greater rank and power.

The Egyptian ass holds a middle place between that of Great Britain and the wild ass, which is more swift of foot than the horse. It is tall and handsome, docile, and having excellent paces, particularly a quick and easy amble. Thus it is well suited to the narrow streets of the towns of Egypt, and is therefore commonly used for riding by persons of the middle and lower classes. The mules are

¹ "*Cyperus Papyrus*, Linn.—Arab. *berdy*, Damiatine" *Description de l'Égypte*, tom. xix. 71. Other *Cyperus* are described at pp. 125-6 and 130-2 of the same volume.

handsome, but noted for vice, and for not being sure-footed.

The cattle are short-horned, rather small, and, as of old, very beautiful, speaking artistically. They are exceedingly quiet in disposition, and much valued for agricultural labour by the people, who therefore very rarely slaughter them for meat, and then only for the Franks. Buffaloes of an uncomely appearance and of a dark slaty colour, strikingly contrasting with the neat cattle, abound in Egypt. When voyaging on the Nile, one often sees them standing or lying in the river by herds. They are very docile, and the little children of the villagers often ride them to or from the river. They are sometimes slaughtered, but their flesh is tough and coarse. Sheep (of which the greater number are black) and goats are abundant in Egypt, and mutton is the ordinary butcher's meat. Swine are very rarely kept, and then almost wholly for the Franks, the Copts generally abstaining from eating their meat. It appears that the ancient Egyptians, though not forbidden this flesh, rarely ate it, perhaps because it is extremely unwholesome in a hot climate.

The Muslims consider dogs unclean, and therefore those of Cairo and most of the towns are half-wild and without masters, living upon offal, and upon food thrown to them by humane persons. In the villages, however, and particularly in the Thebais, their case is better, for they are kept as guards to protect live stock from thieves, and from hyenas and other wild animals, which come from the deserts by night in quest of prey. The common dog of Egypt is generally of a sandy colour and strong, though not remarkable for courage; but in Upper Egypt, about Thebes, there is a fierce breed of dogs with wiry hair, generally black, and much esteemed for courage by their masters. Cats are as numerous in Cairo as dogs, and many of them are as homeless. They are, however, liked by the natives, who assign as their reason that Mohammad was fond of cats. This may perhaps be regarded as a relic of the veneration in which they were held by the ancient Egyptians. It is not a little curious, that there is at Cairo a royal foundation for the support of destitute cats. The author of this charity was the famous Memlook sultan, Edh-Dháhir Beybars, whose humane intentions have of late years been sadly neglected by the trustees.

The wolf, fox, jackal, and hyena chiefly inhabit the deserts and waste places of Egypt, and lurk in the ancient tombs and deserted quarries. The wild cat is also found in that country, though it is not common. The weasel abounds in Cairo, and is proverbial for its mischievous and revengeful disposition, and rats and mice are not among the least of the plagues. The ichneumon, jerboa, hare, and hyrax are likewise natives of Egypt or its deserts, and the tame rabbit is kept for food.

The beasts of the chase of the Egyptian deserts are antelopes of various kinds, and the wild ass, esteemed by the Arabs and Persians to be the prince of game, which is found in the southern part of the Eastern Desert. The most beautiful of the antelopes is the gazelle, which is often tamed and kept in the large courts of the houses of Cairo. In Lower Egypt, principally in the desolate marshes near the Mediterranean, the wild boar is found and occasionally hunted. It is, however, a timid animal, so that the sport is not, like boar-hunting elsewhere, exciting and dangerous.

From the representations in the tombs we see that in old times the hippopotamus was one of the wild beasts of the country. It has now retreated above the First Cataract, the southern boundary of Egypt. The crocodile has retreated in the same manner, and instead

of being found throughout the Nile in Egypt, is rarely seen even in Lower Nubia. The name of the island of Elephantine, situate a little to the north of the First Cataract, bearing the same signification in hieroglyphics as in Greek, makes it probable that at some remote period elephants were found in Upper Egypt, though now they are not seen north of Abyssinia.

In exploring the tombs and dark parts of the temples the traveller is annoyed by crowds of bats, which extinguish his candle, fly into his face, and cling to his clothes, sometimes rendering examination impossible without a lantern. One species is very large, but the common one is small.

Birds of prey are numerous in Egypt, and of many kinds. Of the most remarkable are three species of large naked-necked vultures—the Arabian, the sociable, and the fulvous; as well as the smaller species called the aquiline vulture. The aquiline vulture has a feathered neck, and when standing is by no means a handsome bird, but it is much to be admired when on the wing from the contrast of the black and white of its plumage, and the steady manner in which it soars in circles. Perhaps the bearded vulture breeds in the most lofty parts of the desolate mountains of the Eastern Desert; for when the French army was in Egypt, one of these birds was killed. It is said to have been of extraordinary size, measuring more than 14 Parisian feet, or more than 15 English, from point to point of its expanded wings. Several species of eagles and falcons, two kinds of hawks, the common buzzard, and the moor-harrier live in Egypt, or visit that country, according as they are migratory, erratic, or sedentary. The common kite abounds at Cairo, and is one of the chief scavengers of the city, the others being the crow, the aquiline vulture, the half-wild dog, and the cat. The ruins and tombs of Egypt, and the modern houses, scarcely ever in perfect repair, shelter owls of various kinds.

The Spanish sparrow, which differs little from that of Britain, the water-wagtail, linnet, and larks are among the birds of Egypt. The kind of kingfisher which is commonly seen on the Nile, perched on some eminence, and darting suddenly to seize a fish, is very inferior in its plumage, which is speckled, black and white, to the common kingfisher, which is also occasionally seen. The beautiful hoopoe is among the least rare birds, and there are also three species of bee-eaters. The hoopoe may be often seen in Cairo, where it is regarded with some reverence, as the bird of Solomon. Crows of the kind which we call the Royston crow are very numerous at Cairo. Birds of the swallow tribe, the wood pecker, and the cuckoo are also known in Egypt.

In the metropolis, in the towns and villages, and in the fields, no bird is more common than the pigeon, tame or wild. Pigeon-fancying is a favourite amusement of all classes at Cairo, and in the villages the pigeon-houses are often loftier than the huts upon which they are raised. Tourists on the Nile inflict great loss on the poor peasantry by recklessly shooting these tame birds. Wild turtle-doves build in the courts of the houses of the capital. These courts often serve for the purpose of poultry-yards, in which fowls wander about without any care being taken of them, except that food is occasionally thrown to them. They are consequently meagre, and produce very small eggs. Turkeys, ducks, and geese are kept in the same manner.

Quails migrate to Egypt in great numbers; and sand-grouse, called by the natives *kata*, from their cry, are common in the deserts. There also the Arabs, like the ancient Egyptians, hunt the ostrich. A red-legged partridge is likewise found in Egypt.

The islands of the Nile, the sand-banks which appear when the river is low, the lakes and marshes, the sheets

of water caused by the inundation, and the mountains near the river, are the favourite resorts of many kinds of wading and of web-footed birds.

Of the waders the most interesting would be the sacred ibis of Egypt, if that bird be now found there. But it does not appear certain that only one species was anciently held sacred, and if so that this is the *Ibis religiosa* of Cuvier now known in Egypt. The Egyptian plover is famous on account of the story, which modern observation has confirmed, related by Herodotus respecting it and the crocodile. Among the most common waders are the spur-winged plover, the snow-white egret, which has been erroneously called the ibis, and the pelican. The cormorant, too, is often seen, as are wild geese and ducks, both of several kinds.

Of the many reptiles the crocodile occupies the first place. It is seldom observed in the present day in Upper Egypt. Some years ago it was usual south of Asyout to see several crocodiles basking in the sun in the heat of the day on a sand-bank; at the approach of a boat they would quickly plunge into the stream. They rarely attack a human being, but it is unwise to bathe in the river at places where they are reputed to be fierce, and to bathe at any distance from a boat in the part of Upper Egypt where they are found. It is said that the crocodile's common mode of attacking a person on shore, who is near the river's edge, is to approach stealthily and sweep him into the stream by a blow of his tail, the great weapon of all the lizard-tribe. The smaller saurians are found in great numbers: of these a species of chameleon may be mentioned.

Serpents and snakes are among the most common reptiles, and are of various kinds, including the deadly cerastes and cobra di capello. The house snakes, however, which are numerous at Cairo, are harmless.

Fishes abound in the Nile and in the Lake Menzeleh. The modern inhabitants of the country are partial to fish as food, but they say that only those fishes which have scales are wholesome. The fishes of the Nile are generally insipid in comparison to those of the sea; though a few of them, particularly the bultee (*Labrus niloticus*, Linn.), the kishr (*Perca nilotica*), and the binaee (*Cyprinus bynni*, Arted.), are of a delicate flavour.

One of the commonest insects is the dangerous scorpion. Its sting is very painful, and, if no remedy is applied, sometimes fatal, particularly if a person is stung in the heel.¹ Large spiders are abundant, including more than one species of *solpuga*, incorrectly called tarantulas by the Europeans, and believed by the natives to be very venomous, but this is most likely an error. Egypt has ever been famous for what may be termed insect-plagues, but not to the extent that has been asserted by some modern travellers. Caution will enable one partially to escape the attacks of fleas and bugs, and altogether to avoid the more dreaded insect usually spoken of with them. Beetles of various kinds are found, including that which was anciently held sacred, the scarabæus. Locusts are seldom seen, and very rarely in large numbers. When, however, such is the case, they commit great havoc in the fields and gardens, reminding one of the account of the plague of locusts which preceded the Exodus, and the remarkable passage in the book of Joel (ii. 1-11) describing an invading army as a destructive flight of locusts. Sometimes they merely cross the valley of Upper Egypt, and leave the mark of their passage in desolated fields, entirely stripped of verdure; and at other times they spread themselves for days, or even weeks, over the cultivated lands, committing far more extensive mischief.

¹ A little ipecacuanha, made into a paste with water and applied externally to the place stung, has produced, in the many instances in which the writer has known it used, almost instant relief.

Bees are kept in Egypt, and their honey is much prized by the inhabitants, who usually eat it in a clarified state. It is inferior to that of England, and also to the famous Greek honey. Butterflies and methis of many kinds are observed in the fields. There are plantations of mulberry trees in the eastern part of Lower Egypt, for the rearing of silk-worms. The manufacture of silks was a Government monopoly, but has lately ceased to be so. The silks of Egypt are generally inferior to those of Syria and other Eastern countries, though some have been produced of great excellence. Among the other insects may be mentioned the common fly, rightly deserving a place among the plagues of Egypt, as does also the mosquito, which, however, is not found throughout the country.

Ancient Inhabitants—In the following remarks on the ancient Egyptians great assistance has been derived from the valuable work of Sir Gardner Wilkinson on their Manners and Customs, which has made us better acquainted with them than we are with any other people of antiquity. From the representations of their monuments, and from the mummies which have been unrolled, we can form an accurate idea of the personal characteristics of the ancient Egyptians. In consequence of a misconception of a passage in Herodotus (ii. 104), and confused notions respecting the inhabitants of Africa, it has been often supposed that the Egyptians were very nearly allied to the negro race. A careful examination of the most distinct data in our possession has, however, produced a far different result; and it is now acknowledged that they were more related to the Caucasian than to the negro type. It has also been shown that most of the modern inhabitants have preserved many of the characteristics of their ancient predecessors, and that it is, therefore, erroneous to suppose that they are chiefly of Arab origin, although the intermixture of Arab blood has so much changed the national type that it would not be safe to describe the earlier people from the appearance of the present. Nevertheless, one is often struck, among the remains of ancient monuments, by the similarity of an early representation to some one of the natives standing by, priding himself upon an Arab origin, and repudiating the reproach that he is of the race of Pharaoh.

Judging from the monuments and mummies, the countenance of the ancient Egyptians was oval, and narrower in the case of the men than of the women. The forehead was small and somewhat retiring, but well-shaped; the eyes large, long, and generally black; the nose rather long, and with a slight bridge; the mouth expressive, with rather full lips, and white and regular teeth; the chin small and round, and the cheek-bones a little prominent. The hair was long, full, crisp, somewhat harsh, and almost always black. The beard was worn in so artificial a mode that one cannot judge whether it was full or not. The skin of the men was dark brown; that of the women varied from olive to pink flesh-colour in different persons. The colour of the women was natural, and the darker hue of the men the result of exposure to the sun, and the scantiness of their clothing explains why their faces were not darker than the rest of their bodies.

The dress of the ancient Egyptians did not much vary at different periods. Under Dynasty IV. it was, however, simpler than under the Empire. As most monuments remain of the Empire, the dress of the inhabitants at that time will be described, and this description will apply, in its main particulars, to the earlier and later times of their ancient history.

The men of all classes either had shaven heads, with skull caps, or wore their own hair, or wigs, very full, and in numerous plaits or curls, falling to the shoulders, but sometimes much shorter and in the form of a bag; there

is, indeed, reason to suppose that the practice of shaving the head was universal, except among the soldiers. All the hair of the face was also shaven, except in the cases of kings and great persons, who had a small formal beard, possibly artificial, beneath the chin.

The king was distinguished from his subjects by the richness of his apparel. His head-dress was sometimes his own hair, or the wig, alone; and at others he wore the high crowns of Upper and Lower Egypt, the former being a kind of conical helmet, and the latter a short cap with a tall point behind, worn outside the other. He is also occasionally represented with another form of high cap. The figure of an asp, the emblem of royalty, is often tied just above his forehead. His beard was about three inches long, and one inch broad and deep, and formally plaited.

The simplest royal dress was a kilt, usually reaching nearly to the knees, rather full in front, having a girdle above, from which hung before a broad band, richly ornamented, and peculiar to the king, like the lion's tail (natural or artificial) which was attached to it behind, and reached nearly to the ground. Sometimes a large and full shirt was worn over the kilt, descending almost to the ankles, and having wide sleeves reaching to the elbow. This outer dress is occasionally simply a skirt. Both these dresses were usually of white linen, and the outer dress was apparently very fine and transparent. Sandals were worn on the feet, and the ornaments were armlets, bracelets, both flat and broad, and deep necklaces.

The ordinary costume of men of the upper and middle classes was the same as that of the king, the short kilt, with sometimes the long shirt or skirt of fine linen above it, tied in various forms. Their beards were very short, scarcely exceeding an inch in length, and of a formal square shape, and they wore the full hair or wig, or a skull-cap. They generally went barefoot, but sometimes used sandals. The priest was occasionally clad in a leopard's skin, either tied or thrown over the shoulder, or worn as a shirt, the fore legs forming sleeves. Military personages are often represented with helmets, and sometimes with short coats or corslets of plate-mail. The royal princes were distinguished by a side lock apparently curiously plaited.

The men of the lower class wore the kilt and girdle alone, or, especially when engaged in laborious work, went altogether naked. They shaved the head and face, and had no head-covering but the skull-cap. The soldiers had kilts of different kinds, and coats or corslets of plate-mail, and either wore full hair or helmets.

The dress of the queen consisted of a tight skirt, descending to the ankles, supported by shoulder-straps, and bound at the waist by a girdle, with long ends falling in front. Over this was usually worn a full shirt of fine linen, with wide sleeves reaching below the elbows, and having a broad skirt falling to the ground. It much resembles the upper dress of the king, or of men of the richer classes. The queen was distinguished by her head-dress, which was in the form of a vulture with outspread wings, the bird's head projecting over the forehead, and the wings falling on either side, while the tail extended behind. Sometimes the queen is also known by the royal asp above her forehead, and at other times she is represented with various forms of head-dress. The queen also wore sandals. (For illustrations of royal dress see *COSTUME*, vol. vi., p. 457-8.)

The dress of ladies was the same as that of the queen, without the distinguishing ornaments, but they frequently appeared in the under garment or skirt alone. The women of the lower class wore that garment only, and sometimes it was much shorter than that of the ladies, particularly when they were engaged in manual labour. The women's hair was worn in the same manner as the men's, but it was of greater length, usually reaching about half-

way from the shoulders to the waist, being rarely longer, and sometimes much shorter. It was ornamented in various ways, but the general form was always the same.

The children of all ranks were very simply dressed, when clad at all, though those of rich persons were sometimes attired as their elders. Boys were distinguished by the side-lock, which the princes, as before mentioned, wore in a peculiar fashion.

Religion.—The credit which the Egyptian priests enjoyed in antiquity for a knowledge of philosophy led to the expectation among modern scholars that, when hieroglyphics were read, the world would recover a lost body of human speculation. The first results disappointed this expectation, but later studies have gone far to justify it. The statement of what those studies have achieved may be divided into the two main subjects—the teaching as to the gods and that as to man's duties and destinies, rites and ceremonies coming under both heads.

Had the Egyptians any idea of one God?—in other words, is their religion a complex structure raised upon a recognized monotheistic foundation? The Egyptian religious writings are held by M. de Rougé to give an affirmative answer to this question. They speak of one supreme being, self-existent, self-producing, the creator of heaven and earth, called the double god or double being, as the parent of a second manifestation. From the idea of a supreme deity, at once father and mother, producing a second form, probably originated a first triad like the triads of father, mother, and son frequent in Egyptian mythology. To the local divinities the attributes of this supreme deity are given, as though they were mere personifications: that they were originally so is, however, not certain. Ra, the sun, is indeed spoken of as this supreme being, but this appears to have been a later phase of opinion. (De Rougé, "*Études sur le Rituel Funéraire*," *Rev. Arch.*, n s., i. 356 seqq.) It was probably an attempt to substitute a popular materialistic belief for a philosophical creed. A significant instance of this tendency is perhaps seen in the endeavour of a king of Dynasty XVIII to abolish all worship but that of the solar disk—sun-worship in its most material form.

A very ancient moral tract, the papyrus of Ptah-hotep, composed under Dynasty V., although a purely Egyptian work, mentioning Osiris and a divinity who may be a form of Osiris, yet speaks constantly of God as if the author had the idea of one God.¹

It also appears from one remarkable fact that this idea prevailed in Egypt before the conversion of the nation to Christianity. The Copts took care to eliminate from their vocabulary all the words connected with the religion of their forefathers, substituting for them Greek equivalents. Their term for God is, however, not Greek but Egyptian, *noy*, the hieroglyphic neter. They also used it for heathen objects of worship, god or goddess. These uses must therefore have been prevalent in the vulgar dialect when it was first written in Coptic.

Though it cannot reasonably be doubted that the Egyptians had a distinct idea of monotheism, this idea was mixed up with the basest polytheism. The double character which we perceive in the race and the language, both partly Nigritian, partly Semitic, is equally evident in the religion. Every town in Egypt had its sacred

¹ "L'idée abstraite de la Divinité intervient fréquemment dans le texte, comme si l'auteur avait la notion de l'unité et de l'indivisibilité divine. Mais cette manière de parler n'appartient pas exclusivement à cet antique document. On la rencontre fréquemment dans les textes plus modernes et notamment au Rituel. D'ailleurs le nom d'Osiris et celui de Dieu double crocodile suffisent pour nous démontrer que nous avons affaire à un monument de pure origine égyptienne." Chabas, "*Le plus ancien livre du monde*," *Rev. Arch.* xv 16

animal, or fetish, and every town its local divinities. As the animal worship was associated with higher ideas by the union of an animal's head with the body of a man in the figures of divinities, so the local divinities were connected with the monotheistic idea by intermedial forms, principally identifying them with Ra, who thus was the generally received form of the notion of one god. According to this view monotheism was not the parent of polytheism, but in a later phase connected with it.

One great change affected the essential ideas of the Egyptian religion. For many centuries Seth, specially the divinity of Lower Egypt, who seems to have represented then, as certainly afterwards, the destructive power of nature, held a place in the Pantheon, although regarded as the adversary of Osiris and thus of mankind, whom, however, he finally befriends. He seems thus to have a character of necessary evil. At length, after the Empire, he was expelled from the Pantheon. This may have been because the worship of Seth was repugnant to a reigning house of Asiatic origin, which might have held the Persian dualism which identified physical and moral evil. It may have been because Seth had been considered to be the divinity of the eastern neighbours of Egypt, and with their success and the fall of Egyptian supremacy had come to be thought hostile to that country. If this were the cause, the kings who proscribed his worship could have had no relation to the nations supposed to reverence Seth. In effect the change identified physical and moral evil and destroyed the earlier philosophical notions on the subject, besides introducing some confusion into the Pantheon.

Herodotus speaks of orders of gods, Manetho of divine dynasties. The explanation is to be found in the worship at each town of a cycle of gods. This cycle is called "the society of the gods," or "the nine gods" (M. de Rougé does not admit the second rendering except as a plural of excellence ("Études," *Rev. Arch.*, n.s., i. 237). The number varies at different places and in different lists at the same place, but is always nearly or exactly nine. The Egyptians themselves explained this cycle as the self-development of Ra; the other gods were in this view his attributes (De Rougé, *l.c.* 236, 237; *Rit.* xvii. 2, 3). Two forms of the cycle acquired the highest importance as representing the systems of the learned men of Memphis and Thebes, the successive great capitals of Egypt.¹

The two systems are thus given by Professor Lepsius:²—

MEMPHITE SYSTEM	THEBAN SYSTEM
1. Ptah (Παῖ, "Ἡφαίστος")	1. Amen ("Ἀμμων, Ζεὺς.")
2. Ra ("Ἥλιος")	2. Mentu (Μέντω.)
3. Shu (Σῶς)	3. Atmu (Ἀτμ.)
Tefnet	4. Shu
4. Seb (Κρόνος)	Tefnet.
Nut ("Πῦα")	5. Seb.
5. Hesiri ("Ὅσιρις, Διόνυσος), and	Nut.
(6.) Hes ("Ἥσις, Δημήτηρ.")	6. Hesiri.
6 (7.) Set (Σῆθ, Τυφῶν), and	Hes.
Nebti (Νέφθις)	7. Set.
7. (8.) Har ("Ἦρος, Ἀπόλλων), and	Nebti.
Hat-har ("Ἀῶρ, Ἀφροδίτη")	8. Har.
	Hat-har.
	9. Sebek.
	Tefnet [consort of Mentu?]
	Peut (or Pit?) [consort of Atmu?]

The views of Professor Lepsius on the origin and constitution of these systems, with such modifications as later

¹ These have been called the systems of Memphis and Thebes. The local cycle of Memphis was, however, not the system of Manetho which has been called Memphite, and has a distinct local character (Brugsch, *Geogr. Inschr.*, i. 237).

² Shu, true spelling since discovered, is here put for Mu.

researches have suggested, may now be given. We first observe that the two systems are but variations, and may be treated as one. They consist of male divinities, most of whom are associated with goddesses. These goddesses hold an inferior place, and are not to be counted in reckoning the number of the order, except perhaps Isis, whose importance is much greater than that of the others. An examination of the various forms of the two systems immediately suggests that they increased in course of time, Ptah and Amen, the chief gods of Memphis and Thebes, having been added for state reasons. The order thus reduced consists of two groups, the group of Ra, and that of Osiris. The group of Ra is wholly of solar gods, the group of Osiris begins with Seb and ends with Hathor. Sebek then stands alone, but he is wanting in the older lists, and is only an addition of the Theban system.

The solar group consists of Ra, or else Mentu and Atmu, and Shu. Mentu and Atmu are merely a division of Ra into his two chief phases, the rising and the setting sun, the sun of the upper and of the lower world. Both are solar divinities (Brugsch, *Geogr. Inschr.*, i. 254) Shu, the solar light, is the son of Ra or of Mentu or Atmu, Tefnet, the goddess associated with him, is the daughter of Ra.

The Osiris group is not genealogically connected with the solar group. The central point of the group is found in Osiris, with his consort Isis and his opponent Seth. Seb and Nut are merely extensions of the group upwards. They are, however, spoken of as parents of the gods, showing that they represent the commencement of a series. Osiris, Isis, Seth, and Nephthys were usually considered their children, and Horns, the child of Osiris and Isis Hathor is associated with Horns, but her genealogical place is not clear. It is, however, certain that she is of the family of Osiris. The characteristics of this group are predominantly cosmic; this is true of the myth of Osiris, and consequently of the whole group, and is especially evident in the cases of Osiris and Isis, Seth, and Seb and Nut.

How did these two groups come to be united in a single series? Professor Lepsius argues that this was due to the influence of Thuis, the oldest Egyptian royal seat, from which the first historic king Menes came to Lower Egypt and founded Memphis. Thuis at a very early time merged into the more famous Abydos. Abydos was the great seat of the worship of Osiris, which spread all over Egypt, establishing itself in a remarkable manner at Memphis. All the mysteries of the Egyptians and their whole doctrine of the future state attach themselves to this worship. Osiris was identified with the sun, and the union of the two groups was thus not forced. Both had indeed a common origin. Sun-worship was the primitive form of the Egyptian religion, perhaps even pre-Egyptian. The first development was the myth of Osiris, due to the importance of Thuis, just as the rise of Memphis put Ptah, an abstract idea of intellectual power, even before Ra. So the rise of Thebes introduced Amen, who was identified in the form Amen-ra with Ra, and as an intellectual principle placed before the physical solar powers. This argument derives great weight from the relative position given to the two groups, the solar divinities coming first, and from the circumstance that the religious reform under Dynasty XVIII. suppressed everything but material sun-worship, as though this had been the primitive belief of Egypt.³ M. de Rougé, in his examination of the Egyptian *Ritual*, comes to a similar but more definite result in treating

³ See Lepsius, *Ueber den ersten ägyptischen Götterkreis und seine geschichtlich-mythologische Entstehung.* Berl. Akad., 1851.

of the mythological elements of the important seventeenth chapter. He traces the solar gods to Heliopolis, and considers the Osiris myth as probably derived from Abydos, and added at a later time.¹ Professor Lepsius does not admit the Heliopolite origin of the solar group, on account of the small political importance of Heliopolis. Yet the circumstance that the chief divinities of that city, which had the sacred name Per-aa, the abode of Ra, were Atmu, Shu, and Tefnet (*Rit* xviii. 4, *ap.* Brugsch, *Geogr. Inschr.*, i. 254, *cf.* 255) seems conclusive.²

Some account may now be given of these divinities in the order of the lists, the later additions being noticed last and then lesser divinities. It will be impossible to give more than the simplest particulars, and many names in the Pantheon must be omitted altogether.

Ra, the sun, is usually represented as a hawk-headed man, occasionally as a man, in both cases generally bearing on his head the solar disk, round which the ureus, symbolic of royal power, is sometimes coiled. His symbol is either the solar disk or the hawk. Ra had the most general worship of any Egyptian divinity, except Osiris. The worship of Osiris under his own name was more common than that of Ra under his, but this was in some degree compensated for by the union of Ra with other gods besides solar ones, such as Amen, Num, Sebck, forming the compound divinities Amen-ra, Num-ra, Sebck-ra (Lepsius, *Erst. Aeg. Götterkreis*), and by his being the type of sovereignty, so that each king was a Ra son of Ra. This importance of his worship was due to the adoption of Ra as the leading representative of the supreme being, from whom indeed he is sometimes undistinguishable in the *Ritual*, though as already noticed this does not seem to have been the primitive opinion, for there are evidences of his inferiority to the supreme god and to Osiris (De Rougé, "Études," *Rev. Arch.*, i. 358). In the religious paintings he is the supreme being, carrying on in his course a constant warfare with and triumph over evil, represented by the great serpent Apap, a wholly evil being, not a divinity. His career resembles that of Osiris, but with notable differences. Ra is purely solar. He is rarely associated with any consort, and if so associated his consort is a female Ra (Lepsius, *Erst. Aeg. Götterkreis*). He is always victorious. He protects mankind, but has nothing in common with them. Osiris on the other hand is only solar because he is the beneficent power of nature. He is constantly associated with Isis. He has a life-long conflict with a maleficent power, his brother or son Seth, who is not wholly evil. Vanquished and killed he recovers his life and wins, but it is rather Horus his son who wins, and Horus, a sun-god, is the direct link with Ra in the Osiris family. Osiris protects mankind because his life resembled theirs. If he did not live on earth, at least his tomb was shown there. At Heliopolis two animals sacred to Ra were revered, the black bull Mnevis, sacred to Ra and Atmu, and the Phoenix (Beunni) sacred to Ra. Both are connected with Osiris, the bull by the worship of Apis at Heliopolis, the Phoenix as also representing Osiris (Brugsch, *Geogr. Inschr.*, i. 257, 258). In addition the sacred Persea-tree was revered at Heliopolis.

In the attempt under Dynasty XVIII. to establish sun-worship in an original or ideal simplicity, the only representation is the solar disk with the ureus entwined round it, and rays ending in human hands, one of which offers the symbol of life to the worshipper. The great sun-temple then founded contained no statue whatever (Lepsius, *Erst. Aeg. Götterkreis*).

Mentu and Atmu may best be noticed together as merely two phases of Ra, representing, as already stated, the rising and the setting sun, the sun of the upper and the lower world. Their twin-character is seen in the circumstance that Mentu was worshipped at Southern An (Hermontis) and Atmu at Northern An (Heliopolis, the On of the Bible). Mentu, or Mentu-ra, is represented as Ra with the tall plumes of Amen, Atmu in a human form. Both cannot be distinguished from Ra except that probably their attributes were more restricted, and while Mentu seems to be within limits identical with Ra, the human form of Atmu may perhaps hint a relation to Osiris.³

¹ "Il est facile d'apercevoir, dans tous ces caractères, les symboles osiriens, qui composaient probablement la doctrine primitive d'Abydos, se superposant aux emblèmes d'Héliopolis" (*Rev. Arch.*, n. s., i. 359, 360). M. Mariette, on the other hand, writes "Originairement Osiris est le soleil nocturne, il est la nuit primordiale; il précède la lumière; il est par conséquent antérieur à Ra, le soleil diurne" (*Jour. Boul.*, 1869, 100).

² Shu is, however, not mentioned among the divinities of Heliopolis in the great Papyrus of Ramesses III. *Records of the Past*, vi. 52 *seqq.*

³ In the 17th chapter of the *Ritual* the justified dead is called in his new condition *Tum*, equivalent to Atmu. This may be merely

Shu is light, and is a type of celestial force, for he is represented supporting the goddess of heaven. M. de Rougé remarks that it is curious to find in this ancient cosmogony the principle of force identified with the luminous principle ("Études," *Rev. Arch.*, i. 225, 236). His figure is human and he sometimes bears on his head the ostrich-feather, which, though the initial of his name, must here have its symbolical sense of "truth." The relation of light and truth is not less remarkable than that of light and force. Tefnet, associated with Shu in the eye, is represented with the head of a lioness. This is the most common compound form of Egyptian goddesses, as the hawk-headed of the gods. Both are connected with solar worship. The lioness was probably chosen as the highest form of the family to which the luminous-eyed cat, one of the most popular of the sacred animals, belonged.

Seb stands at the head of the family of Osiris. He is represented in human form like his consort Nut. They are called "father of the gods" and "bearer of the gods." Seb was the god of the earth (De Rougé, *Ibid.* 238), and Nut the goddess of heaven. Her name means the abyss, though curiously the primordial abyss is called, in ch. xvii. of the *Ritual*, nu, in the masculine (*Ibid.* 359).

Osiris, in Egyptian Hesi-ri, is usually represented as a mummy, wearing the royal cap of Upper Egypt, which may indicate the Thinite origin of his worship, or that, as Horus and Seth were the special divinities of Upper and Lower Egypt, so he was particularly connected with the upper country. His cap is usually flanked by ostrich plumes, which probably have a reference to Ma-t the goddess of truth and justice. The myth of Osiris is the most interesting because the most human part of Egyptian mythology. It is impossible to attempt a full account of it: the materials have yet to be gathered. We cannot accept the treatise *On Isis and Osiris* as representing the older form of the myth. In different documents we seem to trace its growth, and notably do we find in those later than Dyn. XXII. the change due to the altered theory of good and evil. Yet the general outlines are the same in what we may reasonably hold to be the earliest documents. It is these that are, as far as possible, used here.

Osiris is essentially the good principle: hence his name Un-nefer, the good being, rather than the revealer of good (Maspero, *Histoire Ancienne*, 38). Like Ra he is the creator, and like him in perpetual warfare with evil. His brother, or son, Typhon, Seth (Set), is his opponent. They are light and darkness, physical good and evil, the Nile and the desert, Egypt and the foreign land. Osiris is certainly moral good, Seth is to a certain extent moral evil. Throughout the *Ritual* they are in conflict for right and wrong, for the welfare and destruction of the human soul. In ch. xvi., which was preserved intact from a remote age, this conflict appears. Seth is, however, not there distinctly named as the opponent of Osiris, except in the glosses, which may be as old or (like the case of the Mishna and the Gemara) older than the text, and once in the text he appears as joining with Horus his adversary in accomplishing the final condition of the deceased who had reached the abode of happiness (ver. 35), and on the other hand, one gloss explains the executioner of souls to be Seth, but otherwise Horus the elder, brother of Osiris, who is but a variation of the younger Horus (ver. 33). Yet the opposition of Osiris and Seth is a perpetual combat. Osiris is vanquished. He is cut in pieces and submerged in the water. Watched by his sisters, Isis his consort and Nephthys the consort of Seth, he revives. Horus his son avenges him, and with the aid of Thoth, or reason, he destroys the power of Seth, but does not annihilate him. The myth is a picture of the daily life of the sun, combating darkness yet at last succumbing to it, to appear again in renewed splendour, as the young Horus a solar god triumphs over Seth. It is also a picture of human life, its perpetual conflict and final seeming destruction, to be restored in the new youth of a brighter existence. In this view suffering is not wholly evil, but has its beneficent aspect in the accomplishment of final good. There are two ways of explaining the origin of this myth. Either we may regard Osiris as the sun of the night, and so the protector of those who pass away into the realm of shades, or we may suppose that once taken as the type and ruler of mankind in the after state, the hidden sun was naturally chosen to represent him, the sun being with the Egyptians the source and governor of all life. Those who make the solar idea the first form of the myth have to explain its specially human aspect, and particularly why we see no such aspect in any deep sense in the case of Atmu the sun of the night in the group of solar divinities.

It will be easily seen how such a story took hold of the affections of the Egyptians. Osiris was the type of humanity, its struggles, its sufferings, its temporary defeat, and its final victory. The living, and still more the dead, were identified with him. Under his name, without distinction of sex, they passed into the hidden place

because the word *tum* has the sense man, and may be thus a play upon the name of the divinity (*cf.* De Rougé, "Études," 350, 351), but it is more likely that *Tum* is here used as Osiris everywhere to indicate the divine quality of the justified.

(Amenti), the divine world below (Ker-ueter), to be protected by him in their conflict with Seth and his genii, and to have their final state determined by him as their judge. It was to Osiris that the prayers and offerings for the dead were made, and all sepulchral inscriptions, except those of the oldest period, are directly addressed to him. As Isis is a form of the female principle, Osiris, the sun and the Nile, was considered in one phrase to be the male principle. The Osiris of Mendes was the name of this form, which was more especially known by the name of Mendes.

The three most famous of those more sacred animals which were worshipped as individuals, not as a class, were the bulls Apis and Mnevis and the Mendesian goat. Of these Apis and the Mendesian goat were connected with the worship of Osiris. Manetho says that all these animals were first reckoned among the gods under a very early Egyptian Pharaoh, Kamephis, in Egyptian Ka-kau, second king of Dyn. II.¹ It is very characteristic of the Egyptian religion that the reverence for Osiris should have taken this grossly-material form.

The bull Apis, who bears in Egyptian the same name as the Nile, Hâpi, was worshipped at Memphis. Here M. Mariette discovered a series of the tombs of these bulls, with tablets recording the reigns in which they were buried, and in several cases further exact particulars of date, thus affording important chronological evidence. Apis was considered to be the living emblem of Osiris, and was thus connected with the sun and the Nile, and the chronological aspect of both explains his being also connected with the moon. On the death of an Apis, a successor was sought for and recognized by certain marks. He was then inaugurated and worshipped during his lifetime. (See Apis.)

Setapis, or Scapis, in Egyptian Hesiri-Hâpi, is the defunct Apis, who has become Osiris. The great extension of the worship of Setapis, after the importation of his statue by Ptolemy I., was merely a development of long existing Egyptian ideas. Hence the rapid spread and great popularity of this worship. (See Setapis.)

The Mendesian goat had no special name. He is called the Ram. He was considered an emblem of Ra and Shu as well as of Set and Osiris, but probably he was chiefly sacred to Osiris, and in his solar aspect, which would thus introduce the relation to the more markedly solar gods. The seat of his worship was Mendes in the eastern part of the Delta, where Dr Brugsch has discovered a very interesting stela of the reign of Ptolemy II., Philadelphus, giving the history of the finding and inauguration of a sacred ram, and of the honour paid to him and to his temple. His worship was similar to that of Apis, but of a grosser form, inasmuch as the goat or ram was a symbol of the productive force of nature.²

Isis, or Hes, represented as a woman bearing on her head her emblem the throne, or the solar disk and cow's horns, is the female form of Osiris. Unlike Ra, the Osiris family have consorts; but no one is so distinctly as Isis a counterpart and of equal importance. Though the place of Isis is not as significant as that of Osiris in the myth to which they belong, she is necessary to it, and this is probably the reason why she attained an importance beyond the other Egyptian goddesses except only Hathor, who is but another Isis.

Seth, the Egyptian Set, usually called by the Greeks Typhon, is represented with the head of a feline animal, having a pointed snout and high square ears. He was the brother or son³ and opponent of Osiris, the divinity of the enemies of Egypt, and the chief of the powers which fought with the human soul in the after life. He certainly represents physical evil. It would be easy to account for his worship in Egypt were it not for his appearing as the enemy of gods as well as of men. There is indeed something illogical in his holding a place in the Pantheon, which gains consistency by his expulsion, though the consequent confusion of moral and physical evil was detrimental to ethical ideas. It is remarkable as showing the Egyptian notion of Seth while he was still worshipped, that in the Tombs of the Kings at Thebes, those whose names are composed with his, Setee I. and II., and Set-nekht, use instead the name of Osiris. This seems to have been sometimes done afterwards by a change in the inscriptions, but still at the time when the tombs were first completed, and thus while the reverence of Seth, as is shown

by these royal names, was in full bloom (Lepsius, *Erst. Aeg. Götterkreis*). The subsequent change of opinion as to Seth, his identification with moral evil, and his consequent expulsion from the Pantheon have been already noticed. In consequence his figure and name are usually effaced on the monuments, and other gods take his place in the cycles in which he had a position. In later times Seth is the enemy of all good, feared and hated, but no longer revered. The date of the change is as yet undetermined. It has been usually assigned to the Bubastite kings who composed Dyn. XXII. M. Mariette has discovered the curious fact that one of those kings, a hitherto unknown Osorkon, altered the figure of Seth in the legends of Ramses II at Tams to that of a Set-Ra (*Musee Boulay*, p. 273). Was this the beginning of the change?

Nephthis, or Nebti, the sister of Osiris and Isis, and consort of Seth, does not, as far as the Egyptian documents tell us, share his character. It is rather as the sister of Isis that she there appears, aiding her in her labours to recover and revive Osiris. Thus like Isis she is a protector of the dead, and her figure and worship escaped the fate of those of Seth.

Horus, or Har, is in the cycles the son of Osiris and Isis. There is also a Horus the elder, Haroeris, Har-der, brother of Osiris, and a Horus the child, Harpoerates, Har-pe-khruti, son of Osiris and Isis, and two other forms, Har-Hut, the Horus of Hut or Apollinopolis Magna, and Har-em-akhu, "Horus in the horizon." Horus is generally hawk-headed, and thus a solar god connected with Ra. This connection is perhaps strongest in the form Har-em-akhu, worshipped at Heliopolis sometimes even as Ra-Har-em-akhu. The most interesting form is that of Horus as the son and avenger of Osiris, Osiris being identified with the sun of the night, Harus is naturally the sun of the day. From this identification arose the idea of an infant Horus as the rising sun. As Horus took the place of Osiris in the contest with Seth, he became the elder Horus, to be on an equality with his opponent, who seems often the brother rather than the son of Osiris. Specially Horus is the ruler of Upper Egypt, and the typical king of Egypt as much as Ra. It is indeed so hard to distinguish Horus from Ra that it seems impossible to hold any opinion but that they had their origin in separate religious systems.

Hathor, Athor, or Hat-har, whose name means "the abode of Horus," is hard to distinguish from Isis.⁴ She was worshipped with Isis at Denderah (Dümichen, *Baukunde der Tempelanlagen von Dendera*, 3, 4) and Dr Brugsch even supposes the local goddess to have been Isis-Hathor (*Geogr. Inschr.*, i. 202, 203), but this he has not proved, for the representations and titles are different for the two goddesses (*cf.* Dümichen, *l.c.*). The cow was sacred to both Hathor and Isis, and both wear the disk and cow's horns. Hathor in the form of a cow plays an important part in Amenti (*cf.* Dümichen, *ibid.* 21, Mariette, *Musee Boulay*, 118, 119). Curiously she is more widely revered than even Isis. She is really the female counterpart of Osiris. She was, like him, worshipped throughout Egypt, and the great temple of Adfoe contains a list of over three hundred names of the goddess in her local forms (Dümichen, *ibid.* 20). Still more remarkably, in late times, the cow, here the symbol of Hathor, not seldom takes the place of the name of Osiris as applied to women deceased: instead of taking the form of Osiris, they take that of Hathor (*ibid.* 21). It is characteristic of the Egyptian religion that this irregularity should occur, and we may well hesitate to attempt to define the place of Hathor in the Pantheon (Mariette, *Musee Boulay*, 118), though M. Dümichen has made this endeavour in a very interesting passage, that could be accepted had he given sufficient authority from the monuments, and not shown traces of the influence of Greek interpretation, besides too great a tendency to reason on the negative evidence of the simple statements of the earlier monuments (*ibid.* 20, *seqq.*).

Pthah, or Ptah, the Egyptian Hehpiastus, is the first to be noticed of the divinities introduced into the chief cycles after their formation. His name is one of the Egyptian words which can be recognized letter for letter in Hebrew (פֶּתַח "he opened, began," and פֶּלֶל "carved"); and the sense is similar. Ptah is thus the divine architect (*cf.* Brugsch, *Historie*, 2d ed., 21). He was the chief god of Memphis, worshipped under a human form, sometimes as a pigmy, supposed to be an embryo. He was the creative force, but seemingly not as the sun. Though when connected with the local form of Osiris worshipped at Memphis under the name Sekeri-Hesiri, and then called Ptah-Sekeri-Hesiri, he is sometimes hawk-headed, this is rather with a reference to Horus than to Ra. Perhaps Professor Lepsius's view that he is put before Ra in the Memphite form of the cycle as an abstract idea of intellectual power is the true one. If so, it seems probable that the worship of Ptah was of foreign origin.

Ammon, the Egyptian Amen, "the hidden," probably owed his importance to the greatness of Thebes, the chief Egyptian seat of his worship. He seems to derive his characteristic from his association with other gods. As Amen-ra he takes the qualities of

¹ M. de Rougé has noticed that the name of this king, "the male of males" or "the bull of bulls," may be connected with the cultus of the sacred bulls, while that of Sakhuris, his successor, contains a symbol, the ram, interchangeable with the goat, which makes it look like a second commemorative medal (*Sit. Prem. Dyn.*, 243, 244). If this be so the names of these early Pharaohs must have been taken on their accession or on some remarkable event, like the throne-names after the introduction of that second name. A change of name during a king's reign for a religious reason is seen in the case of the sun-worshipping Amenoph IV., who took the name of Khen-en-aten.

² *Records of the Past*, viii. 91 s. 72, where the stela of Mendes is translated.

³ It has been usual to call Seth the brother of Osiris; Dr Brugsch prefers to style him his son. (*Hist.*, 2d ed. p. 20, 21). This double relationship is the key to the similar position of Horus, and the identity of Hathor and Isis.

⁴ Dümichen considers Hathor as the female principle to be identical with Isis (*Baukunde von Dendera*, 20).

the sun, as Amen-ra ka-mnt-f, "the husband of his mother," he takes those of Min or Khem, the productive principle. Rarely he has the ram-headed form that Greek notions would lead us to expect.

Sebek, the crocodile-headed god, seems to have held a similar place to Seth. There may have been a time when he was revered throughout Egypt, but in the Græco-Roman period he was a local divinity so disliked in most parts of Egypt that, as already noticed, the Arsinoite nome where he was worshipped does not appear in the geographical lists. His sacred animal the crocodile was held in abhorrence and hunted wherever Sebek was not revered (cf. Brugsch, *Hist.*, 2d. ed., 106, 107).

Thoth, or Taout, is the head of the second cycle in the two principal forms of the cycles. As the chief moon-god he thus takes an inferior place corresponding to that of Ra. He is generally represented as ibis-headed, and frequently bears the disk and crescent of the moon. He is the god of letters and of the reckoning of time, and thus sometimes has solar attributes. The ibis and the cynocephalus were sacred to him. As the deity of wisdom he aids Horus in his conflict with Seth, and records the judgment of the deceased before Osiris. He appears in Phœnician mythology, though not at a period early enough for us to infer that his worship was not borrowed from Egypt. Yet it is not impossible that here, as in the case of Phtha, we have a trace of early Eastern influence. It is at least remarkable that the great seat of his worship, Hermopolis Magna, bearing in ancient Egyptian the civil name Sesennu, also Pe-sesennu and Ha-sesennu, Eight, or the Abode, or House of Eight, is called in Coptic **ⲙⲉⲛⲓⲛⲓⲛ**, or **ⲙⲉⲛⲓⲛⲓⲛ Ⲉ** (-ⲙⲓⲛⲓⲛ, two), where the numeral eight approaches the Semitic form (Brugsch, *Geogr. Inschr.*, i. 219). Was the change in the Coptic numeral due to an ancient form of the name of this celebrated city?

Ma-t, the goddess of truth, succeeds Thoth in a fragment of the list of the dynasties of the gods in the Turin chronological papyrus. She is characterized by the ostrich-feather, the emblem of truth, upon her head. She thus corresponds to Shu, holding the corresponding place. Thoth is called her husband (Lepsius, *Königsbuch*, taf. iii. 22), but she is not his consort at Hermopolis (Brugsch, *Geogr. Inschr.*, i. 220). She is the daughter of the sun. Her place in the myth of Osiris is very important, for it is in her hall, where she is called the Two Truths, that the deceased are judged.

Anubis, or Annp, jackal-headed, probably held in one system the next place to Ma-t. He belongs to the family of Osiris, being called the son of that divinity. He presided over mummification. In the earliest sepulchral inscriptions the divinity addressed is Anubis, not Osiris. No reason has yet been discovered for this. There can be little doubt that Osiris was always intended, and that the earliest inscriptions, for some reason connected with the Egyptian reticence as to this divinity, address Anubis.

The four genu of Amenti were inferior divinities connected with embalming. They were called Amset, Hâpi, Tia-mut-f, and Kebhsenuf. The vases found in Egyptian tombs which bear covers in the forms of the heads of these genu were intended to contain the viscera of the mummy, as it was held to be of importance that every part of the body should be preserved.

The rest of the principal Egyptian gods may now be noticed as far as possible in the order of their importance. It must, however, be remembered, that we are likely to be misled by the abundant monuments of Upper Egypt, and the scantiness of those of Lower Egypt, and that therefore we cannot yet decide which were insignificant members of the Pantheon.

Chnuapha, or Khnum, represented with a ram's head, and to whom the ram was sacred, is the soul of the universe, and thus is spoken of as the creator (Mariette, *Musée Boulaq*, 113). He was specially worshipped in Nubia, and at the First Cataract, with his consort Sati, the goddess of the inundation (Brugsch, *Geogr. Inschr.*, i. 150, *seqq.*). He is closely connected with Amen.

The Egyptian Pan, the god of Panopolis, or Chemmis, was Min, or Khem, the productive principle, a form of Osiris. He was worshipped at Panopolis with a form of Isis as his consort (Brugsch, *ibid.*, 212, *seqq.*). It is remarkable that he was connected with Amen at Thebes, for the myth of Amen and that of Osiris are singularly apart.

Mendes, or Ba-neb-tet, is merely a local form of Osiris, lord of Mendes, connected with the worship of the sacred ram, or Mendesian goat (Brugsch, *ibid.*, 267, 268, 271, 272, *Records of the Past*, viii. 91).

Neith, or Nit, worshipped at Saïs, identified by the Greeks with Athena, is one of the few goddesses who held the first place in local worship. From the idea of a supreme being, single and self-producing, arose that of a female aspect of this being. Thus Khnum is called, as representing this being, "the father of fathers, the mother of mothers" (Mariette, *Musée Boulaq*, 113). This would suggest the personification of a female principle. This principle seems specially represented by the higher goddesses, like Neith, who is called "the mother who bare the sun, the first born, but not

begotten, born" (Brugsch, *Geogr. Inschr.*, i. 247). She wears the crown of Lower Egypt, where she was principally worshipped.

Pakht, or Sekhet, and Bast, are two forms of one goddess difficult to distinguish. They are both usually lioness-headed, though sometimes they have the head of the cat, their sacred animal. Pakht was worshipped at Memphis as the consort of Phtha; Bast seems to have held a place at her city Bubastis like that of Neith at Saïs. The monuments identify Hathor with Bast, and Isis with both Pakht and Bast, Hathor being called "Lady of Bubastis," while Isis is spoken of as "bringing misfortune as the goddess Pakht, bringing peace as the goddess Bast" (Champ., *Not. Man*, 192, ap. Brugsch, *Geogr. Inschr.*, i. 276). Pakht and Bast thus represent a double nature, not unlike the two principles in the Osiris myth (Mariette, *Musée Boulaq*, 1106; Brugsch, *Geogr. Inschr.*, i. 275, 276). Pakht and Bast were identified with Artemis (Brugsch, *ibid.*, 224, 275).

Mut, the "mother," consort of Amen-ra at Thebes, is, as her name implies, another embodiment of the female principle, though not in so important a form as Neith, so far as our present knowledge goes.

Khuns, worshipped at Thebes as the son of Amen and Mut, is a lunar divinity wearing the disk and crescent of the moon, his hair being plaited in the side-lock of a child. Sometimes he is hawk-headed, and thus connected with the sun. As a divinity mainly lunar his inferior place is accounted for.

The goddess Suben, identified with Eilethya or Lucina, was worshipped at the town Eilethya. She was especially the mother-goddess, and the goddess of southern Egypt, her symbol, that of maternity, was the vulture (Mariette, *Musée Boulaq*, 121).

The goddess corresponding to Suben was Uati, or Buto, who was the protector of the north, and whose emblem was the uræus serpent.

Onuris, or Anher, was the local deity of the ancient city of Thinis. His functions are not clearly defined.

Imhotep, identified by the Greeks with Æsculapius, was the son of Ptah and Pakht, and with them formed the triad of Memphis. He is probably the god of the sciences, and similar to Thoth (Mariette, *ibid.*, 117, 118).

The Nile as a divinity bears the same name as the sacred Memphite bull, Hâpi, probably meaning "the concealed." He is represented as a man with pendent breasts, to indicate the fertility of the river. A hymn to the Nile by Enna, who flourished under Menptah, the successor of Ramses II. (Dyn. XIX.), shows how completely even an inferior Egyptian divinity was identified with the supreme god, and with the principal members of the Pantheon (*Select Papyri*, xx-xxiii, xxxiv-xxxix; Maspero, *Hymne au Nil*, a critical edition, and *Records of the Past*, iv. 105, *seqq.*, an elegant translation by the Rev. F. C. Cook).

The Egyptian divinities were frequently associated in triads, temples being dedicated to one of these lesser cycles, consisting of father, mother, and child. The child is almost always a son. It is extremely difficult to make out a local triad in several cases, where there were two chief local divinities, or where the chief divinity was a goddess. At Thebes the triad was Amen-ra, Mut, and Khuns, at Memphis, Ptah, Pakht or Sekhet, and Imhotep; at Onchos there were two triads, Sebek, Hathor, and Khuns, and Haruer, Taseu-nefert, and Pnubto-pkhrut, the triad of Nubia and at Elephantine was Nun, Sati, and the goddess Ank-t; at Apollinopolis Magna, Har-Hut, Hat-har, and Har-pkhrut, at Latopolis, Nun, Nebut, and Har-pkhrut, at Hermonthis, Munt, Ra-ta, and Har-pkhrut, and Osiris, Isis, and Horus, throughout Egypt. The third member of the triad always belongs to an inferior rank, and is sometimes a child-god (pkhrut), as will be observed in the three cases in which Har-pkhrut (Harpocrates) occurs, and the similar instance of Pnubto-pkhrut. Much of our knowledge of the Egyptian triads is founded on late documents of the Ptolemaic and Roman temples, and it is possible that the idea may have not been as much developed in earlier times. The whole subject requires a careful investigation.

The Egyptian notions as to the cosmogony are too closely identified with mythology to be very clearly defined. It seems, however, that they held that the heavenly abyss was the abode of the supreme deity, who there produced the sun and the moon as well as the rest of the Pantheon. Yet it is stated in one gloss in the *Ritual* that the abyss itself was the supreme deity (cf. De Rougé, "Études," *Rev. Arch.*, n.s., i. 235, *seqq.*). The aspect of the passages of the *Ritual* in which these ideas are developed seems as if due to the attempt to introduce philosophical ideas into the mythology, as though the Egyptians had some notion of the origin of things independent of that mythology.

The worship of the Egyptian deities was public and

private—that of the temples and that of the tombs. Every town had at least one temple dedicated to the chief divinity of the place, with certain associated gods, and usually, if not always, a living symbol in the form of a sacred animal supposed to be animated by the chief local divinity. The services were conducted by priests, and on occasions by the king, and by scribes, who sometimes formed a college and lived at the temples, the various duties of which required the services of learned men. It is probable that the common people had a very small share in the religious services, the most important of which took place in the smaller inner chambers, which could never have admitted many worshippers. The outer courts, and still more the great inclosures containing the whole group of temple-buildings, must, however, have been the chief public resort for business and pleasure. There were no other public buildings, or, apparently, market-places. Like the modern mosque, the temple must have been the chief centre of the population.

The worship in the tombs was not local. It was always connected with Osiris or a divinity of the same group, and had the intention of securing benefits for the deceased in the future state. It took place in the chapel of each tomb of the wealthy; and though properly the function of the family, whose members officiated, the inscriptions invite all passers-by, as they ascend or descend the Nile, overlooked by the sepulchral grottoes, to say a prayer for the welfare of the chief person there buried.

The sacrifices were of animals and vegetables, with libations of wine, and burning of incense. Human sacrifice seems to have been practised in early periods. The monuments do not mention it, but Manetho speaks of its having been abolished, at least at one place, by Amosis, no doubt the first king of Dynasty XVIII. The reference is probably to some barbarous usage during the great war with the Shepherds¹.

The origin and destiny of man in the Egyptian religion is now known to us on the authority of its own documents, which in the main confirm what Greek writers had already stated on the subject. The aspect of the Egyptian teaching is either that of a simple theory, which was afterwards mythically interpreted, or of a union of such a theory with a superstition existing side by side with it. In the famous seventeenth chapter of the *Ritual* it is possible, as De Rougé has done with extraordinary skill, to extract from the text a consistent theory which the glosses confuse by the mythological turn they give to the simple statements of the text. Notwithstanding this difficulty, it is sufficiently clear that the Egyptians attributed to the human soul a divine origin, that they held that it was throughout life engaged in the warfare of good and evil, and that after life its final state was determined by judgment according to its doings on earth. Those who were justified before Osiris passed into perpetual happiness, those who were condemned into perpetual misery. The justified took the name of Osiris, the judge, under which they indeed already appeared for judgment.

Had this plain outline been left unfilled by the priests, the Egyptians might have been credited with a lofty

philosophy. Unfortunately, however, a thousand superstitious took the place of the attempt to lead an honest life. In the tombs we find every one who could pay for a sculptured record characterized as justified, every mummy already an Osiris. How was this determined? Possibly there was a council held, which decided that the deceased could be treated as one who was certain of future happiness. It is, however, more probable that the learning certain prayers and incantations, the performance of ceremonies, and the whole process of embalming, together with the charms attached to the mummy, and prayers said by those who visited the tomb, were held to secure future happiness. In reading the *Ritual* we are struck by the small space given to man's duties as compared with that filled by incantations and charms. The human mind must have lost sight of the value of good and seized upon the multifarious equivalents which needed nothing to be done by way of either self-restraint from evil or active benevolence. Thus as we look at the documents we see a noble idea lost in a crowd of superstitious fancies; as we look at the Egyptians as they lived, we trace the effect of the indomitable good, and yet find it always greatly alloyed with evil. The Egyptian idea of the future state is the converse of that of Socrates. It is no little incident of human weakness, like the request to sacrifice a cock to Æsculapius, which injures but does not destroy a harmonious whole, a mere glimpse of truth is seen through thick mists peopled with the phantoms of the basest superstition.

In the long course of ages the Egyptian ideas as to the future state seem to have undergone changes, not in themselves, but in the manner in which they were regarded. The vast labour expended on the Pyramids, and their solid simplicity, are in striking contrast with the elaborate religious representations of the tombs of the kings of Dynasties XIX. and XX. So, too, the sculptures on the walls of the tombs of subjects of the earlier kings, representing the everyday life of duty and pleasure, give place to funereal and religious scenes in the later periods. These were fashions, but they show the changed mood of the national mind. It is only in a tablet of the age of the Ptolemies that Greek ideas assert their predominance in a touching lament addressed from the land of shades, which no longer speaks of active happiness, but in its place of purposeless oblivion (Birch, "Two Tablets of the Ptolemaic Period," *Archæologia*, xxxix. 22, 23).

Laws and Government—We are gradually gaining an insight into the Egyptian laws. This is principally due to M. Chabas, the third volume of whose *Mélanges Égyptologiques* mainly consists of essays, nearly all by himself, on texts relative to the administration of justice under the Pharaohs. His general results confirm the accuracy of what Diodorus Siculus and Plutarch state on the subject. It was to be expected that their evidence would have been good as to matters which could not have been easily misunderstood, and which must in the case of Diodorus have been personally observed. In this matter the two sets of authorities may fairly be combined.

The government of Egypt was monarchical. It was determined as early as the rule of Dynasty II., according to Manetho, that women could reign. Accordingly we find instances of queens regnant. Their rule, however, seems to have been disliked, and they are passed over in the lists made under Dynasty XIX., when, it may be observed, the royal family seems to have been affected by Shemite influences. The royal power can scarcely have been despotic, although under certain kings it became so. It is sufficient to compare Assyrian and Babylonian with Egyptian history and documents to perceive a marked difference. The earliest monuments indicate a powerful local aristocracy holding hereditary functions. Those of

¹ According to Plutarch, Manetho stated that human sacrifices were anciently practised at Eleuthia (*De Is et Osir* i cap 73), whereas Porphyry says, on the same authority, that Amosis abolished them at Heliopolis (*De Abst.*, p 199). As, however, according to Porphyry they were sacrificed to Hera, who would well correspond to Suben, goddess of Eleuthia, not to any goddess of Heliopolis, it is probable that Heliopolis is an error for Eleuthia (*Ἡραίου πόλει* for *Εὐλεθούλας πόλει*, as in the other passage where this is a correction for *Ἰδύβιας πόλει*), but the two citations are very different. According to Porphyry, Amosis substituted waxen figures for the victims. The figure called the "Bride of the Nile," now annually thrown into the river at the cutting of the Canal of Cairo, is said to represent a girl annually sacrificed in former times.

the Empire (Dynasties XVIII.-XX.) scarcely indicate any such class. Even the princes are no longer a royal clan, but the children of the reigning sovereign. The whole system of government rests with the king, who appoints all the functionaries and dismisses them at his pleasure. Hence arose a vast and corrupt bureaucracy, to which the decay of Egypt may have been mainly due. At all times the country was governed by nomarchs and lesser officers. In the earliest period these were local magnates whose office was at least sometimes hereditary, and whose interest it was to promote the welfare of their districts. Under the Empire governments seem to have been mere places of profit given by favour and held by force and corruption, according to the Turkish method.

The laws were administered by judges appointed by the king. It is certain that commissions for an occasion were thus formed. We do not know that there were judges appointed for life; but it is probable that such was the case, as it must have been the duty of a class to be thoroughly acquainted with the written laws. A legal scribe may, however, have been attached to each commission.¹ All the particulars of each case, though not necessarily submitted in writing, were recorded, and the decision was written. The process was conducted with great care, and the culprit examined on his oath. The punishments probably were not extremely severe. For murder, but not for manslaughter, death was the penalty. Adultery was severely punished, perhaps rather by custom than by law. Theft was rigorously prosecuted. For sacrilegious theft the criminal was punished with death. The laws relating to debt are not yet well known. They appear to have been complicated by a system of loans and pawning, and to have been subject to modifications. Of the tenure of land we know little. The temple-lands seem to have been held in perpetuity, and this was probably the case with private domains in the earliest period (*De Rougé, Six Prem. Dyn.*, 255, note 1).

Army—We know little as yet of the organization of the Egyptian army, but much of its arms and mode of conducting warfare. It consisted from very early times of foreigners as well as Egyptians. The Egyptian troops seem to have been a military caste, though not in the strictest sense, and to have had certain lands allotted to them. There were two main divisions of the army,—a chariot-force, in which each chariot contained an archer and a charioteer, and was drawn by two horses, and a force of foot-soldiers variously armed, chiefly heavy infantry, armed with shield and spear, sword, axe, or mace, and light infantry, with bow, and axe or falchion, as well as slingers. It may be noticed that flint-tipped arrows were used in the chase. We know nothing of the military manœuvres, but it is evident that the troops were drilled to move in formations, and that the art of besieging was as well understood as by the Assyrians, in the mode of attacking the enemy's fort as well as in that of protecting the soldiers.

Manners and Customs—The subjects of the walls of the Egyptian tombs and the hieratic papyri tell us much of the domestic life of the ancient people. The education in the earliest age seems to have been more manly and more simple than in that of the Empire, when the college of a temple or the miniature court of a great officer was the school instead of the estate of the lauded proprietor. This system, however, gave almost his only chance of advance-

¹ M. Chabas has given the constitution of a tribunal under Dynasty XX. It was held at the great assizes of Thebes, and presided over by the pōharch, with nine inferior judges, including his three assessors, who were a royal controller, a majordomo, and another royal controller, the first prophet of Amen-ra and an inferior prophet, a royal scribe, a captain of cavalry, an ensign of the navy, and the commandant of the city. The last was the prosecutor, and was himself condemned by the other judges on the acquittal of the defendants (*Mélanges*, iii. i. 131, &c.)

ment to a poor man's son, for the very highest posts were open to the successful scholar. (*Cf. Brugsch, Hist.* 2d ed. 16, 17.) Circumcision was practised from the earliest times, but apparently not as a religious rite, and not until the earlier years of childhood had passed. Of the education of girls there is no indication, but, as they afterwards shared the public life of men, and even held posts of importance in the priesthood, it could not have been neglected. It has not been proved that the Egyptians had any definite marriage law. We find, however, that they married but one wife, who is termed the lady of the house, and shares with her husband the honours paid to the deceased. Concubinage was no doubt allowed, but it is seldom that we find any trace of children more numerous than those of legitimate wives could be. The family of Ramses II. is an instance of an Oriental household, and the fifty-two children of Baba, whose tomb is found at Eilethya, may also be cited, though the term children may in this case include other descendants (*cf. Brugsch, ibid.* 176, 177). Ordinarily the aspect of the family is that which it wears in civilized countries. The women were not secluded, and, if they did not take the place of those of republican Rome, it was due to faults of national character rather than the restraints of custom. There was no separation into castes, although many occupations were usually hereditary. As there was no noble caste, there was nothing to prevent the rise of naturally able persons but the growth of the official class, which gradually absorbed all power and closed the avenues to success. The corruption of this class has been remarkably shown by the researches into the Egyptian administration of justice by M. Chabas, who cites lists of robbers of tombs and houses containing the names of scribes and priests, besides a higher grade of servants (*Mélanges*, iii. i. 144, *seqq.*). There are other indications of the social condition of Egypt under the Empire in the complaints of the lower class against the brigandage to which they were subject on the part of persons who found means to interest the highest functionaries, and so escape merited punishment. At the same time it is to be remembered that they had the right of direct appeal to the king (*Ibid.* 173-216). This part of the picture of Egyptian life is strikingly like that of China, and the dislike of foreigners is consistent with the comparison. The lower class being uneducated, and for the most part very poor, was held in contempt by the higher, and this was especially the case with labourers and herdsmen. All handicrafts were considered unworthy of a gentleman, and even the sculptor and painter were not raised above this general level. The only occupations fit for the upper class were priestly, civil, and military, and the direction of architectural and other works which required scientific knowledge, not skill of hand. The servants were of a higher grade than the labourers: not so the slaves, who were generally captives taken in war.

The everyday life of the ancient Egyptians is abundantly represented in the pictures of the tombs from the earliest monumental age to that of the Empire. The rich passed much of their time in hospitality, giving feasts at which the guests were entertained in various ways. The host and hostess sat together, as did other married people, and the other men and women generally were seated apart. The seats were single or double chairs, but many sat on the ground. Each feaster was decked with a necklace of flowers by the servants, and a lotus-flower was bound to the head, on which was also placed a lump of ointment. Small tables were set before the guests, on which were piled meat, fruits, cakes, and other food, and wine-cups were carried round. Before the repast, hired musicians and dancers entertained the company, and often this seems to have been the sole object of invitation.

These two kinds of entertainment are precisely what are customary at the present day in Egypt. Among the amusements of the ancient Egyptians was witnessing the performance of various gymnastic feats. They had several games, one of which probably resembled draughts. Under the old kingdom the chief occupations of the rich seem to have been those of a country life, in its duties, the superintendence of husbandry, of the taking stock of flocks and herds, and of the shipment of produce, and the examination of fisheries, or again in seeing to the efficient work of the people of the estate who were engaged in any craft; and the pleasures of country life filled up the leisure. In ancient times Egypt had far more cover for wild fowl than now. Thus we see from the subjects of the tombs that the rich Egyptian was in the habit of going into the marshes in a canoe, generally with some of his children, to spear the hippopotamus, or more frequently to knock down birds with the curved throwstick. In fowling, a cat was sometimes used as a retriever. At other times he fished in his ponds, or shot or couased with hounds various animals of the antelope kind. Every rich man in the age of the Empire had a chariot, generally drawn by two horses, which he usually drove himself, standing up in it. The life of the ladies was not unlike that of the men, except that they only joined in the sports as spectators. They seem to have passed their time in household matters, in visiting, and in the simplest country pleasures. Occasionally they rode in heavy cars drawn by oxen. Their manners appear to have been indolent and luxurious. Among the lower orders the lighter work usually fell to the women. Both men and women led hard lives, having scanty clothing and poor food; yet the genial climate, in which the wants of the labourer must always have been few, rendered their condition not so painful as one might suppose.

Language and Literature.—The language of the people was the Egyptian, the later form of which, after they had become Christians, is called Coptic. Comparative philology has not yet satisfactorily determined its place. There can be no doubt that it is related to the Semitic family, but it has not yet been proved to belong to it. The grammatical structure is distinctly Semitic, and many roots are common to the Semitic languages. On the other hand, the Egyptian has essential characteristics which detach it from this family. It is monosyllabic, and its monosyllabism is not that from which scholars have endeavoured to deduce Semitic, but rather such as would belong to a decayed condition. This monosyllabism is like that of Syriac. Dr Brugsch strongly affirms the affinity of the Egyptian to the Indo-Germanic as well as the Semitic languages (*Hist.*, 2 ed. 6), but the former relation has to be proved. It has been supposed that the monosyllabism of the Egyptian is due to its having in part originated from a Nigritian source (*Genesis of the Earth and of Man*, 2d ed. 255, *seqq.*). Certainly this is a characteristic of some Nigritian languages, and the want of any large agreement in the vocabulary would be sufficiently explained by the changes that the languages of savage nations undergo from the absence of a literature. It can therefore scarcely yet be asserted with Dr Brugsch that the Egyptian has no analogy to the African languages (*i.e.*), by which, no doubt, he intends those which have no Semitic element. The problem will probably be solved either by a careful study of all the African languages which show traces of Semitic structure side by side with those that are without such traces, or by the discovery of the unknown element in Egyptian in the Akkadian or some other primitive language of Western Asia, which cannot be called Semitic in the recognized sense of the term. During its long history the language underwent little change until it became Coptic. It had two dialects—those of Upper and Lower Egypt,

(Brugsch, *ibid.*); and by degrees a vulgar dialect was formed which ultimately became the national language not long before the formation of Coptic. One curious innovation in the Egyptian language was the fashion under the Ramses family of introducing Semitic words instead of Egyptian ones. From the manner in which these words are spelt it is evident that the Egyptians at that time had no idea of a Semitic element in Egyptian, for they always treat them as foreign words and retain the long foreign forms. The chief change in Coptic was the introduction of many Greek words, especially to supply the place of religious terms eliminated from the vocabulary. The inscribed and written character of Egyptian was the hieroglyphic, a very complex system, which expressed ideas by symbols or by phonetic signs, syllabic and alphabetic, or else by a combination of the two methods. From this was formed the hieratic, a running hand, or common written form of the hieroglyphic, principally used for documents written on papyrus. Its oldest records are not equal in age to the earliest hieroglyphic inscriptions, but probably it is not much later in origin. The demotic or enchorial writing is merely a form of hieratic used for the vulgar dialect, and employed for legal documents from the time of Dyn. XXVI. downwards. The Coptic is written with the Greek alphabet, with the addition of six new letters and a ligature, these letters being taken from the demotic to express sounds unknown to Greek. For further details see the article HIEROGLYPHICS.

Much ancient Egyptian literature has come down to us, and it must be allowed that from a literary point of view it has disappointed expectation. What it tells is full of interest, but the mode of telling rarely rises to the dignity of style. So unsystematic is this literature that it has not given us the connected history of a single reign, or a really intelligible account of a single campaign. The religious documents are still less orderly than the historical. It is only by the severe work of some of the ablest critics during the last fifty years that from those disjointed materials a consistent whole has been constructed.

The most important religious work is the *Funeral Ritual*, or *Book of the Dead*, a collection of prayers of a magical character referring to the future condition of the disembodied soul, which has already been noticed. It has been published by Dr Lepsius (*Das Totenbuch der Aegyptier*) and M. de Rougé (*Rituel Funéraire*), and translated by Dr Birch (*Bunsen's Egypt's Place*, v.). De Rougé, in his most interesting papers in the *Revue Archéologique* (n.s.), has done the utmost that a splendid critical faculty and an unusual mastery of language could achieve to present parts of the work in the most favourable form. Still it must remain a marvel of confusion and poverty of thought. Similar to the Ritual is the Book of the Lower Hemisphere. The other religious works and inscriptions are of a wider range. The temple inscriptions indeed are singularly stilted and wanting in variety, but the papyri contain some hymns which are of a finer style, particularly that to the Nile by Enna, translated by Canon Cook (*Records of the Past*, iv. 105), and that to Hathor, translated by Dr Lushington (*ibid.* viii. 129) and Professor Maspero (*Histoire Ancienne*, 32, *seqq.*). The moral writings have a higher quality than the religious, if we may judge from their scanty remains. The historical writings fall into two classes according to their official or unofficial character. Those that are official present the worst form of the panegyric style, the others are simple though wanting in method. The letters are of more interest, from their lively portrayal of ancient Egyptian manners. In works of fiction there is a greater degree of skill, and in the "Tale of Setna" (*Records of the Past*, iv.) we even find touches of humour. Egyptian literature

is not without its merits, but it has that want of lofty ideas and of charm which is characteristic of the literature of nations which have written very much and have had no other means of addressing mankind.

Science.—Fresh information is being constantly acquired as to the knowledge of science possessed by the ancient Egyptians. Their progress in astronomy is evident from their observations, and still more from the cycles they formed for the adjustment of different reckonings of time. Their knowledge of geometry is attested by their architecture, and by a document on the lands of the temples of Adfoo; and the annual inundation must have made careful surveys and records necessary for the preservation of landed property. Very great mechanical skill must have been needed to move these vast blocks—used in their buildings, sometimes for very long distances, in part by difficult land-routes, and then to place them in position. Considering the want of iron, and of any but the very simplest mechanical appliances, the achievements of the Egyptian architects are an enigma to modern sciences (Brugsch, *Hist.*, 2d ed. 52). Chemistry and metallurgy had also made great progress. The hardening of the bronze tools with which they cut granite is a proof of this, and the manner in which Moses destroyed the golden calf is another evidence. Medicine and surgery were much studied, and the Egyptians were in those sciences only inferior to the Greeks.

Arts.—Of the arts architecture claims the first place, sculpture and painting being subservient to it among the Egyptians. Temples were not built to contain statues, but statues were set up to adorn temples, of which they were a part, and the walls were covered with sculptures and paintings which had a decorative purpose. The group of these arts may therefore be considered as a whole, and thus the principle they expressed may be best discovered. This principle seems not to have been accidental, but a deliberate choice. The country and climate afforded the best means of symbolizing the leading idea of the Egyptian religion in the material forms of art. Life after death was that idea, and it found expression in the construction of tombs as lasting as the rocks on which they rested. The pyramid is the first form of Egyptian art, and modifications of its form, in truncated pyramids, are seen in the main outlines of all later edifices or excavations. The decorations were subordinated to the idea of commemoration, and thus every building was at once religious and historical in its purpose. To this the Egyptian monuments owe a reserved grandeur that is not affected by the symmetrical qualities of hieratic art nor by the use of strongly contrasted colours. The art is always dignified, and the colours, being seen either in strong sunlight outside the monuments, or in dim twilight within them, are never glaring. The effect is exactly what was intended, and would probably not have been produced had the art been more advanced. In the whole range of ancient art Egyptian may take its place next after Greek. Indeed in some instances it excels Greek, as when in animal forms the natural is subordinated to the ideal. The lions from Giseh at Barkal, presented by the fourth duke of Northumberland to the British Museum, are probably the finest examples of the idealization of animal forms that any age has produced.

From these observations we may form some idea of the character of the ancient Egyptians. They were religious, but superstitious; brave without cruelty, but tyrannical, hospitable, but not to strangers. In dress they were plain, but luxurious in their ornaments; simple in their food, but given to excess in wine. With respect for family ties, they were careless in their morals. The women enjoyed great freedom, yet their character does not seem to have been higher than it is among their descendants, subject to the lowering influence of the harem seclusion. Though the

chief object of every man's life was the construction of his tomb, and the most costly personal event was the funeral, the Egyptians were singularly mirthful, delighting in music and the dances, and so given to caricature that even in the representation of a funeral ceremony the artist cannot omit a ludicrous incident. The double origin of the race seems as apparent here as in their physical type and their religion. The generous qualities of the Semite are being perpetually perverted by the inferior impulses of the Nigritian, and again the bright elements of the Nigritian character are strangely darkened by the shadow of the gloomy tendency of the Semites.

The industrial arts were carried to a high degree of excellence by the ancient Egyptians. In weaving and all the processes connected with the manufacture of linen they have never been surpassed. Their pottery was excellent in quality and suitable to its various purposes, and their glass but slightly inferior to that of the Greeks. In the making of furniture, and instruments of music, vessels of metal, alabaster, and other materials, arms and domestic implements, they showed great taste and skill, and their influence on Greek art through the Phœnicians is undoubted, though they did little more than afford suggestions to more skilful artists of Hellas.

The Egyptians had a great variety of musical instruments, the number of which shows how much attention was paid to the art. Various kinds of harps are represented, played with the hand, and of lyres, played with or without the plectrum, and also a guitar. There are other stringed instruments, for which it is difficult to find a modern name. The Egyptians had also flutes, single and double pipes, the tambourine of various forms, cymbals, cylindrical maces, drums of different kinds beaten with the hands or sticks, the trumpet, and the sacred sistrum. The military music was that of the trumpet, drum, and cylindrical maces, but almost all the instruments were used in the temple services. It is impossible to form any conjecture as to the character of the music, unless we may suppose that with many of the old instruments the modern inhabitants have preserved its tradition. It may therefore be mentioned that they are ignorant of harmony, but have fineness of ear and of execution. The musicians often sang or danced while they played. The dances of both men and girls were of various kinds, from what may be called feats of agility to slow movements. The dancers were chiefly girls, whose performances evidently resembled those of their modern successors, and whose clothing was even more transparent or scanty.

Ceremonies.—We know little of the private festivities of the ancient Egyptians. In particular no representation of a marriage ceremony has yet been discovered on the monuments. The greatest ceremony of each man's life was his funeral. The period of mourning began at the time of death, and lasted seventy-two days or a shorter time. During this time the body was embalmed and swathed in many linen bandages, the outermost of which was covered with a kind of pasteboard, which represented the deceased, in the form we call a mummy, as a labourer in the Elysian fields, carrying the implements of husbandry, the face and hands being alone seen, and the rest of the body being painted with subjects relating to the future state, and bearing a principal inscription giving the name and titles of "the Osiris, justified." The viscera were separately preserved in vases having covers in the forms of the heads of the four gods of Amenti. The mummy was inclosed in a case of wood having the same shape, and this was again inclosed, when the deceased was a rich man, within either another wooden case, or more usually a sarcophagus of stone, sometimes of the same form as the mummy, but generally rectangular, or nearly so. The mummy was then placed on a sledge, drawn by oxen or by men, and was frequently taken

to the bank of the river, or the shore of a sacred lake, which was to be crossed in order to reach the place of burial. A sacred boat carrying the mummy, attended by mourners, was towed by another boat, and followed by others containing mourners, offerings, and all things necessary for the occasion (*Anc. Eg.*, pl. 83-86). On reaching the tomb the sarcophagus was placed in a sepulchral chamber, usually at the bottom of a pit, and offerings for the welfare of the deceased were made in a chapel in the upper part of the tomb. One tomb sufficed for each family, and sometimes for some generations; and in the case of the less wealthy, many were buried in the sepulchral chambers of a single pit, above which was no structure or grotto. It has been already noticed that, according to Diodorus, every one was judged by a legal tribunal before the right of burial was permitted, and of this there may be a survival in the practice of the modern Egyptians, which prescribes that a witness must answer for the good character of the deceased before his burial (*Modern Egyptians*, ch. xxviii.). After the burial, offerings were made at stated times each year by the family, and the chief inscription begged the passer-by to say a prayer for the good of the inhabitant of the tomb. These customs led to many abuses. The maintenance of the costly prescribed offerings must have been most inconvenient, and for this and other purposes the burial-grounds were peopled by a tribe of hungry professional embalmers and lower priests, who made their living not only by their profession but also by fraud and even theft. Yet we must admire the generosity with which the Egyptians lavished their riches upon the most tender form of affection. They were repaid not merely by a natural satisfaction, but also by the wholesome recognition that there are unselfish and unproductive uses for wealth.

MODERN INHABITANTS.

[Mr Lane in 1834 estimated the population of Egypt at less than 2,000,000, and gave the following numbers as nearly those of the several classes of which it is mainly composed:—

Muslim Egyptians (fellahs or peasants, and towns-people)	1,750,000
Christian Egyptians (Copts)	150,000
'Osmanliacs, or Turks	10,000
Syrians	5,000
Greeks	5,000
Armenians	2,000
Jews	5,000

the remainder, exclusive of the Arabs of the desert, numbering about 70,000 (*Mod. Eg.*, Introduction).

The last official return (1876) estimates the population of the various provinces as follows:—

Egypt Proper (Upper, Middle, and Lower)	5,252,000
Nubia	1,000,000
Ethiopia	5,000,000
Darfoor, &c	5,700,000

Of the present population of Egypt, the Muslims constitute seven-eighths, and nearly four-fifths of that of the metropolis; and to this class, and more particularly to the people of Cairo, the following sketch of personal characteristics and customs will relate, save in some few cases, which will be distinguished from the rest.

In describing the personal characteristics of this remarkable people, Mr Lane, in the first chapter of *The Manners and Customs of the Modern Egyptians* (which was written just before European influence was felt in the country, and still deservedly ranks as the only book of authority on the subject), says:—

“In general the Muslim Egyptians attain the height of about 5 feet 8 or 5 feet 9 inches. Most of the children under 9 or 10 years of age have spare limbs and a distended abdomen; but as they grow up their forms rapidly improve. In mature age most of them are remarkably well-proportioned; the men muscular and robust;

the women very beautifully formed, and plump; and neither sex is too fat. I have never seen corpulent persons among them, excepting a few in the metropolis and other towns, rendered so by a life of inactivity. In Cairo, and throughout the northern provinces, those who have not been much exposed to the sun have a yellowish but very clear complexion, and soft skin; the rest are of a considerably darker and coarser complexion. The people of Middle Egypt are of a more tawny colour, and those of the more southern provinces are of a deep bronze, or brown complexion—darkest towards Nubia, where the climate is hottest. In general the countenance of the Muslim Egyptians (I here speak of the men) is of a fine oval form: the forehead of moderate size, seldom high, but generally prominent, the eyes are deep sunk, black and brilliant, the nose is straight, but rather thick, the mouth well-formed, the lips are rather full than otherwise, the teeth particularly beautiful, the beard is commonly black and curly, but scanty. I have seen very few individuals of this race with grey eyes; or rather, few persons supposed to be of this race; for I am inclined to think them the offspring of Arab women by Turks, or other foreigners. The Fellahs, from constant exposure to the sun, have a habit of half-shutting their eyes, this is also characteristic of the Bedawes. Great numbers of the Egyptians are blind in one or both eyes. They generally shave that part of the cheek which is above the lower jaw, and likewise a small space under the lower lip, leaving, however, the hairs which grow in the middle under the mouth, or, instead of shaving these parts, they pluck out the hair. They also shave a part of the beard under the chin. Very few shave the rest of their beards, and none their moustache. The former they suffer to grow to the length of about a hand's-breadth below the chin (such at least is the general rule, and such was the custom of the Prophet), and their moustache they do not allow to become so long as to incommode them in eating and drinking. The practice of dyeing the beard is not common, for a grey beard is much respected. The Egyptians share all the rest of the hair, or leave only a small tuft (called 'shoosheh') upon the crown of the head From the age of about 14 to that of 18 or 20 [the women], are generally models of beauty in body and limbs, and in countenance most of them are pleasing, and many exceedingly lovely, but soon after they have attained their perfect growth, they rapidly decline.” The relaxing nature of the climate, and other predisposing causes, contribute to render many of them absolutely ugly at the age of 40. “In the Egyptian females the forms of womanhood begin to develop themselves about the ninth and tenth year. at the age of 15 or 16 they generally attain their highest degree of perfection. With regard to their complexions, the same remarks apply to them as to the men, with only this difference, that their faces, being generally veiled when they go abroad, are not quite so much tanned as those of the men. They are characterized, like the men, by a fine oval countenance, though in some instances it is rather broad. The eyes, with very few exceptions, are black, large, and of a long almond-form, with long and beautiful lashes, and an exquisitely soft, bewitching expression—eyes more beautiful can hardly be conceived their charming effect is much heightened by the concealment of the other features (however pleasing the latter may be), and is rendered still more striking by a practice universal among the females of the higher and middle classes, and very common among those of the lower orders, which is that of blackening the edge of the eyelids both above and below the eye, with a black powder called 'kohl.'”

Both sexes, but especially the women, tattoo several parts of the person, and the latter stain their hands and feet with the red dye of the henné.

The dress of the men of the upper and middle classes consists of cotton drawers, and a cotton or silk shirt with very wide sleeves. Above these are generally worn a waistcoat without sleeves, and a long vest of silk, called *kaftán*, which has hanging sleeves, and reaches nearly to the ankles. The *kaftán* is confined by the girdle, which is a silk scarf, or cashmere or other woollen shawl. Over all is worn a long cloth robe, the *gibbeh* (or *jubbah*) somewhat resembling the *kaftán* in shape, but having shorter sleeves, and being open in front. The dress of the lower orders is the shirt and drawers, and waistcoat, with an outer shirt of blue cotton or brown woollen stuff; some wear a *kaftán*. The head-dress of all is the turban wound round a skull-cap. This cap is usually the red cloth *fez*, or *tarboosh*, but the very poor wear one of coarse brown felt, and are often without the turban. Many professions and religions, &c., are distinguished by the shape and colour of the turban, and various classes, and particularly servants, are marked by the form and colour of their shoes; but the poor

go usually barefoot. The ladies wear a shirt and drawers, a very full pair of silk trousers, and a close-fitting vest with hanging sleeves and skirts, open down the front and at the sides, and long enough to turn up and fasten into the girdle, which is generally a cashmere shawl; a cloth jacket, richly embroidered with gold, and having short sleeves, is commonly worn over the vest. The hair in front is combed down over the forehead and cut across in a straight line; behind it is divided into very many small plaits, which hang down the back, and are lengthened by silken cords, and often adorned with gold coins and ornaments. A small tarboosh is worn on the back of the head, sometimes having a plate of gold fixed on the crown, and a handkerchief is tastefully bound round the temples. The women of the lower orders have trousers of printed or dyed cotton, and a close waistcoat. All wear the long and elegant head-veil. This is a simple "breadth" of muslin, which passes over the head and hangs down behind, one side being drawn forward over the face in the presence of a man. A lady's veil is of white muslin, embroidered at the ends in gold and colours; that of a person of the lower class is simply dyed blue. In going abroad the ladies wear above their indoor dress a loose robe of coloured silk without sleeves, and nearly open at the sides, and above it a large enveloping piece of black silk, which is brought over the head, and gathered round the person by the arms and hands on each side. A face-veil entirely conceals the features, except the eyes; it is a long and narrow piece of thick white muslin, reaching to a little below the knees. The women of the lower orders have the same out-door dress of different materials and colour. Ladies use slippers of yellow morocco, and abroad, inner boots of the same material, above which they wear, in either case, thick shoes, having only toes. The poor wear red shoes, very like those of the men. Among the upper classes, however, the dress is rapidly becoming assimilated to that of Europeans in its most preposterous form.

In religion the Muslim Egyptians are Sunnees, professing the creed which is commonly termed "orthodox," and are principally of the persuasion of the Shâfê'ees, whose celebrated founder, the imâm Esh-Shâfê'ee, is buried in the great southern cemetery of Cairo. Many of them are, however, Hanafees (to which persuasion the Turks chiefly belong), and in parts of Lower, and almost universally in Upper, Egypt, Malikees.

The civil administration of justice is conducted in four principal courts of jurisdiction,—that of the Zâbit, or chief of the police, where trivial cases are summarily disposed of; the Divan el-Khedivi, in the citadel, in which the khedive or his deputy presides, and where judgment is given in cases which either do not require to be referred to the two other courts yet to be mentioned, or which do not fall within their province; the Divan el-Mahkemeh, the court of the *cadi* (kâdee), or chief judge, who must be a Hanafee, and who was formerly a Turk sent annually from Constantinople, but is now appointed by the khedive, and paid a fixed salary of 4000 napoleons a year; and that of the mufti of the Hanafees, or chief doctor of the law, who decides all cases of difficulty. There are besides five minor mahkemehs, or courts, in Cairo, and one in each of the neighbouring towns of Boulâk and Masr El-Ateekah, from which cases are always referred to the court of the kâdee; and each country town has a native kâdee, whose authority is generally sufficient for the villages around. The Council of the 'Ulemâ, or learned men, consists of the sheykh, or religious chief, of each of the four orthodox persuasions, the sheykh of the great mosque called the Azhar, who is of the persuasion of the Shâfê'ees, and is sometimes its sheykh, the kâdee, and the chief (nakeeb) of the Shereefs, or descendants of the Prophet, with several

other persons. This body was until lately very powerful, but now has little influence over the khedive. Cairo is divided into quarters (Hârah), each of which has its sheykh, who preserves order among the people; and the whole city is partitioned into eight larger divisions, each having a sheykh called Sheykh et-Tamn. Various trades also have their sheikhs or chiefs, to whom reference is made in disputes respecting the craft; and the servants have similar heads who are responsible for their behaviour. The country is divided into governments, as before stated, each presided over by a Turkish officer, having the title of mudeer, and subdivided into districts under the control of native officers, bearing the titles "Mamoor" and "Nâzir." A responsible person called Sheykh el-Reled (or "sheykh of the town" or "village") presides over each small town and village, and is a native of the place. It must also be mentioned that the Siâed, or Upper Egypt, is governed by a pasha, whose residence is at Asyoot. Notwithstanding the consistent, able, and in many respects commendable, code of laws which has been founded on the Korân and the Traditions, the administration of justice is lamentably faulty. As is the custom throughout the East, judgment in Egypt is usually swayed by bribes, and a poor man's case is generally hopeless when his adversary is rich. To this rule there have been some notable exceptions, and the memory of a few virtuous judges is cherished by the people; but such instances are very rare. The moral and civil laws observed by the Muslim Egyptians, being those of El-Islâm, will be noticed elsewhere. A great abuse formerly existed in Egypt in the system of consular jurisdiction. Natives were compelled to sue a foreigner before the latter's consul, and in nine cases out of ten lost their cause. Similarly it was very difficult for a foreigner of one nation to obtain justice against one of another nation at the latter's consulate. This abuse has now been done away. At the instance of Nubar Pasha, and after the deliberations of a European commission, three Courts of First Instance at Alexandria, Cairo, and Ismailia, and a Court of Appeal at Alexandria, were established in 1876, presided over by mixed benches of Europeans and natives, the former being the majority, and employing a new code based on the *Code Napoléon*, with such additions from Muslim law as were possible. These courts decide all cases between the Government or native subjects and foreigners, and between foreigners of different nationalities; and there can be no doubt that they will exercise a great influence for good on the administration of justice in Egypt. It is to be hoped that in course of time they may supersede the old native system in all causes. At present they do but supersede the consular system.

It is very worthy of notice, that in Cairo, as in some other Muslim cities, any one may obtain gratuitously an elementary education, and he who desires the fullest attainable education may receive that also without the payment of a single fee, by joining a class of students in a collegiate mosque. The elementary instruction which most boys receive consists chiefly of reading, and learning the Korân by heart; day schools, as charitable institutions, abound in Cairo, and every town possesses its school; a trifling fee to the fikke (or master) is the only expense incurred by the scholars. Girls are seldom taught anything beyond needlework. The children of both sexes, except those of the wealthy, have generally a very dirty and slovenly appearance; and often intentional neglect is adopted to avert the effects of the "evil eye," of which the Egyptians entertain great dread. The children of the upper classes are excessively indulged, while the poor entirely neglect their offspring. The leading doctrines of El-Islâm, as well as hatred for all religions but their own, and a great reverence for their parents and the aged, are early inculcated.

This deference towards parents cannot fail to strike every foreigner who visits Egypt, and does not cease with the children's growth, presenting an example well worthy of imitation in the West. Circumcision is observed at about the age of five or six years, when the boy is paraded, generally with a bridal procession, on a gaily caparisoned horse, and dressed in woman's clothes. Some parents, however, and most of the learned, prefer a quieter and less expensive ceremony (*Modern Egyptians*, chap. xxvii.).

It is deemed disreputable for a young man not to marry when he has attained a sufficient age; there are therefore few unmarried men. Girls, in like manner, marry very young, some even at ten years of age, and few remain single beyond the age of sixteen; they are generally very prolific. The bridegroom never sees his future wife before the wedding night, an evil which is somewhat mitigated by the facility of divorce. A dowry is always given, and a marriage ceremony performed by a *fikce* (a schoolmaster, or one who recites the Koran), in the presence of two witnesses, the ceremony is very simple, but constitutes a legal marriage. The bridal of a virgin is attended with great festivity and rejoicing, a grandee's wedding sometimes continuing eleven days and nights. On the last day, which should be that terminating with the eve of Friday, or of Monday, the bride is taken in procession to the bridegroom's house, accompanied by her female friends, and a band of musicians, jugglers, wrestlers, &c. As before stated, a boy about to be circumcised joins in such a procession, or, frequently, a succession of such boys. A Muslim is allowed by his religion four wives; but advantage is rarely taken of this licence, and very few attempt to keep two wives in one house; the expense and discomfort which polygamy entails act, therefore, as a restriction to its general adoption. A man may, however, possess any number of concubine slaves, who, though objects of jealousy to the legal wife, are yet tolerated by her in consideration of her superior position, and conceded power over them, a power which she often uses with great tyranny; but certain privileges are possessed by the concubine, especially if she have born a son to her master. Such slaves are commonly kept only by grandees, the generality of the Muslim Egyptians being content with one wife. A divorce is rendered obligatory by the simple words "Thou art divorced," and a triple divorce is irrevocable under ordinary circumstances. The harem system of appointing separate apartments to the women, and secluding them from the gaze of men, is observed in Egypt as in other Muslim countries, but less strictly. Mr Lane (*ibid.* ch. vi.) says—"I believe that in Egypt the women are generally under less restraint than in any other country of the Turkish empire; so that it is not uncommon to see females of the lower orders flirting and jesting with men in public, and men laying their hands upon them very freely. Still it might be imagined that the women of the higher and middle classes feel themselves severely oppressed, and are much discontented with the state of seclusion to which they are subjected; but this is not commonly the case, on the contrary, an Egyptian wife who is attached to her husband is apt to think, if he allow her unusual liberty, that he neglects her, and does not sufficiently love her, and to envy those wives who are kept and watched with greater strictness." The females of an Egyptian household never sit in the presence of the master, but attend him at his meals, and are treated in every respect as inferiors. The mother, however, forms a remarkable exception to this rule; in rare instances, also, a wife becomes a companion to her husband. On the other hand, if a pair of women's shoes are placed outside the door of the harem apartments, they are understood to signify that female visitors are within, and a man is sometimes thus excluded

from the upper portion of his own house for many days. Ladies of the upper or middle classes lead a life of extreme inactivity, spending their time at the bath, which is the general place of gossip, or in receiving visits, embroidering, and the like, and in absolute *dolce far niente*. It is therefore no cause for wonder that their tone of morals is generally low. Both sexes are abstemious in their food, though fond of pastry, sweetmeats, and fruit. The principal meals are breakfast, about an hour after sunrise; dinner, or the mid-day meal, at noon; and supper, which is the chief meal of the day, a little after sunset. Coffee is taken at all hours, and is, with a pipe, presented at least once to each guest. Tobacco is the great luxury of the men of all classes in Egypt, who begin and end the day with it, and generally smoke all day with little intermission. Many women, also, especially among the rich, adopt the habit. Men who can afford to keep a horse, mule, or ass, are very seldom seen to walk, and numberless excellent asses are to be hired in Cairo. Ladies always ride asses and sit astride. The poorer classes are of course unable to observe the harem system, but the women are in general carefully veiled. Some of them keep small shops, and all fetch water, make fuel, and cook for their households. The food of the poor is very meagre; flesh meat is rarely tasted by them, and (besides bread) dates, raw cucumbers, and onions are their common food, with soaked beans, roasted ears of Indian corn, &c.

In their social intercourse the Muslim Egyptians are regular, and observe many forms of salutation and much etiquette; yet they are very affable, entering into conversation with strangers at shops and elsewhere. Their courtesy and dignity of manner are very striking, and are combined with ease and a fluency of discourse. Of their mental qualifications Mr Lane (*ibid.* ch. xii.) remarks—"The natural or innate character of the modern Egyptians is altered, in a remarkable degree, by their religion, laws, and government, as well as by the climate and other causes; and to form a just opinion of it is therefore very difficult. We may, however, confidently state that they are endowed, in a higher degree than most other people, with some of the more important mental qualities, particularly quickness of apprehension, a ready wit, and a retentive memory. In youth they generally possess these and other intellectual powers; but the causes above alluded to gradually lessen their mental energy." Their principal virtues are piety and strong religious feeling, a strict observance of the injunctions of El-Islam, and a constantly professed sense of God's presence and over-ruling providence, combined, however, with religious pride and hypocrisy. Their common discourse is full of asseverations and expressions respecting sacred things, often, however, used with a levity which it is difficult for a person unacquainted with their feelings easily to reconcile with their respect for God. They entertain an excessive reverence for their Prophet; and the Koran is treated with the utmost respect—never, for example, being placed in a low situation—and this is the case with everything they esteem holy. They are fatalists, and bear calamities with perfect resignation to the Divine will. Their filial piety and respect for the aged have been before mentioned, and benevolence and charity are conspicuous in their character; poverty is therefore not accompanied by the distressing circumstances which too frequently attend it in Europe. Humanity to dumb animals is another virtue, and cruelty is openly discountenanced in their streets, even to unclean animals, this is, however, unfortunately wearing off in consequence of their intercourse with Franks. Their affability, cheerfulness, and hospitality are remarkable, as well as frugality and temperance in food and drink, scrupulous cleanliness, a love of country, and honesty in the payment of debt. It should

go usually barefoot. The ladies wear a shirt and drawers, a very full pair of silk trousers, and a close-fitting vest with hanging sleeves and skirts, open down the front and at the sides, and long enough to turn up and fasten into the girdle, which is generally a cashmere shawl, a cloth jacket, richly embroidered with gold, and having short sleeves, is commonly worn over the vest. The hair in front is combed down over the forehead and cut across in a straight line; behind it is divided into very many small plaits, which hang down the back, and are lengthened by silken cords, and often adorned with gold coins and ornaments. A small tarboosh is worn on the back of the head, sometimes having a plate of gold fixed on the crown, and a handkerchief is tastefully bound round the temples. The women of the lower orders have trousers of printed or dyed cotton, and a close waistcoat. All wear the long and elegant head-veil. This is a simple "breadth" of muslin, which passes over the head and hangs down behind, one side being drawn forward over the face in the presence of a man. A lady's veil is of white muslin, embroidered at the ends in gold and colours, that of a person of the lower class is simply dyed blue. In going abroad the ladies wear above their indoor dress a loose robe of coloured silk without sleeves, and nearly open at the sides, and above it a large enveloping piece of black silk, which is brought over the head, and gathered round the person by the arms and hands on each side. A face-veil entirely conceals the features, except the eyes, it is a long and narrow piece of thick white muslin, reaching to a little below the knees. The women of the lower orders have the same out-door dress of different materials and colour. Ladies use slippers of yellow morocco, and abroad, inner boots of the same material, above which they wear, in either case, thick shoes, having only toes. The poor wear red shoes, very like those of the men. Among the upper classes, however, the dress is rapidly becoming assimilated to that of Europeans in its most preposterous form.

In religion the Muslim Egyptians are Sunnees, professing the creed which is commonly termed "orthodox," and are principally of the persuasion of the Shâfe'ees, whose celebrated founder, the imâm Esh-Shâfe'ee, is buried in the great southern cemetery of Cairo. Many of them are, however, Hanâfees (to which persuasion the Turks chiefly belong), and in parts of Lower, and almost universally in Upper, Egypt, Mâlikees.

The civil administration of justice is conducted in four principal courts of judicature,—that of the Zâbit, or chief of the police, where trivial cases are summarily disposed of, the Divan el-Khediv, in the citadel, in which the khedive or his deputy presides, and where judgment is given in cases which either do not require to be referred to the two other courts yet to be mentioned, or which do not fall within their province, the Divan el-Mahkemeh, the court of the cadi (kâdee), or chief judge, who must be a Hanafee, and who was formerly a Turk sent annually from Constantinople, but is now appointed by the khedive, and paid a fixed salary of 4000 napoleons a year; and that of the muftæ of the Hanâfees, or chief doctor of the law, who decides all cases of difficulty. There are besides five minor mahkemehs, or courts, in Cairo, and one in each of the neighbouring towns of Boolâk and Masr El-'Ateekah, from which cases are always referred to the court of the kâdee, and each country town has a native kâdee, whose authority is generally sufficient for the villages around. The Council of the 'Ulemâ, or learned men, consists of the sheykh, or religious chief, of each of the four orthodox persuasions, the sheykh of the great mosque called the Azhar, who is of the persuasion of the Shâfe'ees, and is sometimes its sheykh, the kâdee, and the chief (naakeb) of the Shereefs, or descendants of the Prophet, with several

other persons. This body was until lately very powerful, but now has little influence over the khedive. Cairo is divided into quarters (Hârah), each of which has its sheykh, who preserves order among the people; and the whole city is partitioned into eight larger divisions, each having a sheykh called Sheykh et-Tamn. Various trades also have their sheikhs or chiefs, to whom reference is made in disputes respecting the craft; and the servants have similar heads who are responsible for their behaviour. The country is divided into governments, as before stated, each presided over by a Turkish officer, having the title of mundeer, and subdivided into districts under the control of native officers, bearing the titles "Mamoor" and "Nâzir." A responsible person called Sheykh ol-Beled (or "sheykh of the town" or "village") presides over each small town and village, and is a native of the place. It must also be mentioned that the Sa'eed, or Upper Egypt, is governed by a pasha, whose residence is at Asyoot. Notwithstanding the consistent, able, and in many respects commendable, code of laws which has been founded on the Korân and the Traditions, the administration of justice is lamentably faulty. As is the custom throughout the East, judgment in Egypt is usually swayed by bribes, and a poor man's case is generally hopeless when his adversary is rich. To this rule there have been some notable exceptions, and the memory of a few virtuous judges is cherished by the people; but such instances are very rare. The moral and civil laws observed by the Muslim Egyptians, being those of El-Islâm, will be noticed elsewhere. A great abuse formerly existed in Egypt in the system of consular jurisdiction. Natives were compelled to sue a foreigner before the latter's consul, and in nine cases out of ten lost their cause. Similarly it was very difficult for a foreigner of one nation to obtain justice against one of another nation at the latter's consulate. This abuse has now been done away. At the instance of Nubar Pasha, and after the deliberations of a European commission, three Courts of First Instance at Alexandria, Cairo, and Ismaïlia, and a Court of Appeal at Alexandria, were established in 1876, presided over by mixed benches of Europeans and natives, the former being the majority, and employing a new code based on the *Code Napoléon*, with such additions from Muslim law as were possible. These courts decide all cases between the Government or native subjects and foreigners, and between foreigners of different nationalities, and there can be no doubt that they will exercise a great influence for good on the administration of justice in Egypt. It is to be hoped that in course of time they may supersede the old native system in all causes. At present they do but supersede the consular system.

It is very worthy of notice, that in Cairo, as in some other Muslim cities, any one may obtain gratuitously an elementary education, and he who desires the fullest attainable education may receive that also without the payment of a single fee, by joining a class of students in a collegiate mosque. The elementary instruction which most boys receive consists chiefly of reading, and learning the Korân by heart; day schools, as charitable institutions, abound in Cairo, and every town possesses its school, a trifling fee to the fikee (or master) is the only expense incurred by the scholars. Girls are seldom taught anything beyond needlework. The children of both sexes, except those of the wealthy, have generally a very dirty and slovenly appearance; and often intentional neglect is adopted to avert the effects of the "evil eye," of which the Egyptians entertain great dread. The children of the upper classes are excessively indulged, while the poor entirely neglect their offspring. The leading doctrines of El-Islâm, as well as hatred for all religions but their own, and a great reverence for their parents and the aged, are early inculcated.

This deference towards parents cannot fail to strike every foreigner who visits Egypt, and does not cease with the children's growth, presenting an example well worthy of imitation in the West. Circumcision is observed at about the age of five or six years, when the boy is paraded, generally with a bridal procession, on a gaily caparisoned horse, and dressed in woman's clothes. Some parents, however, and most of the learned, prefer a quieter and less expensive ceremony (*Modern Egyptians*, chap. xxvii.).

It is deemed disreputable for a young man not to marry when he has attained a sufficient age; there are therefore few unmarried men. Girls, in like manner, marry very young, some even at ten years of age, and few remain single beyond the age of sixteen; they are generally very prolific. The bridegroom never sees his future wife before the wedding night, an evil which is somewhat mitigated by the facility of divorce. A dowry is always given, and a marriage ceremony performed by a *fikie* (a schoolmaster, or one who recites the Koran), in the presence of two witnesses, the ceremony is very simple, but constitutes a legal marriage. The bridal of a virgin is attended with great festivity and rejoicing, a grandee's wedding sometimes continuing eleven days and nights. On the last day, which should be that terminating with the eve of Friday, or of Monday, the bride is taken in procession to the bridegroom's house, accompanied by her female friends, and a band of musicians, jugglers, wrestlers, &c. As before stated, a boy about to be circumcised joins in such a procession, or, frequently, a succession of such boys. A Muslim is allowed by his religion four wives; but advantage is rarely taken of this licence, and very few attempt to keep two wives in one house; the expense and discomfort which polygamy entails act, therefore, as a restriction to its general adoption. A man may, however, possess any number of concubine slaves, who, though objects of jealousy to the legal wife, are yet tolerated by her in consideration of her superior position, and conceded power over them, a power which she often uses with great tyranny; but certain privileges are possessed by the concubine, especially if she have born a son to her master. Such slaves are commonly kept only by grandees, the generality of the Muslim Egyptians being content with one wife. A divorce is rendered obligatory by the simple words "Thou art divorced," and a triple divorce is irrevocable under ordinary circumstances. The hareem system of appointing separate apartments to the women, and secluding them from the gaze of men, is observed in Egypt as in other Muslim countries, but less strictly. Mr Lane (*ibid.* ch. vi.) says—"I believe that in Egypt the women are generally under less restraint than in any other country of the Turkish empire; so that it is not uncommon to see females of the lower orders flitting and jesting with men in public, and men laying their hands upon them very freely. Still it might be imagined that the women of the higher and middle classes feel themselves severely oppressed, and are much discontented with the state of seclusion to which they are subjected; but this is not commonly the case, on the contrary, an Egyptian wife who is attached to her husband is apt to think, if he allow her unusual liberty, that he neglects her, and does not sufficiently love her, and to envy those wives who are kept and watched with greater strictness." The females of an Egyptian household never sit in the presence of the master, but attend him at his meals, and are treated in every respect as inferiors. The mother, however, forms a remarkable exception to this rule, in rare instances, also, a wife becomes a companion to her husband. On the other hand, if a pair of women's shoes are placed outside the door of the hareem apartments, they are understood to signify that female visitors are within, and a man is sometimes thus excluded

from the upper portion of his own house for many days. Ladies of the upper or middle classes lead a life of extreme inactivity, spending their time at the bath, which is the general place of gossip, or in receiving visits, embroidering, and the like, and in absolute *dolce far niente*. It is therefore no cause for wonder that their tone of morals is generally low. Both sexes are abstemious in their food, though fond of pastry, sweetmeats, and fruit. The principal meals are breakfast, about an hour after sunrise; dinner, or the mid-day meal, at noon; and supper, which is the chief meal of the day, a little after sunset. Coffee is taken at all hours, and is, with a pipe, presented at least once to each guest. Tobacco is the great luxury of the men of all classes in Egypt, who begin and end the day with it, and generally smoke all day with little intermission. Many women, also, especially among the rich, adopt the habit. Men who can afford to keep a horse, mule, or ass, are very seldom seen to walk, and numberless excellent asses are to be hired in Cairo. Ladies always ride asses and sit astride. The poorer classes are of course unable to observe the hareem system, but the women are in general carefully veiled. Some of them keep small shops, and all fetch water, make fuel, and cook for their households. The food of the poor is very meagre, flesh meat is rarely tasted by them, and (besides bread) dates, raw cucumbers, and onions are their common food, with soaked beans, roasted ears of Indian corn, &c.

In their social intercourse the Muslim Egyptians are regular, and observe many forms of salutation and much etiquette; yet they are very affable, entering into conversation with strangers at shops and elsewhere. Their courtesy and dignity of manner are very striking, and are combined with ease and a fluency of discourse. Of their mental qualifications Mr Lane (*ibid.* ch. xii.) remarks—"The natural or innate character of the modern Egyptians is altered, in a remarkable degree, by their religion, laws, and government, as well as by the climate and other causes, and to form a just opinion of it is therefore very difficult. We may, however, confidently state that they are endowed, in a higher degree than most other people, with some of the more important mental qualities, particularly quickness of apprehension, a ready wit, and a retentive memory. In youth they generally possess these and other intellectual powers; but the causes above alluded to gradually lessen their mental energy." Their principal virtues are piety and strong religious feeling, a strict observance of the injunctions of El-Islam, and a constantly professed sense of God's presence and over-ruling providence, combined, however, with religious pride and hypocrisy. Their common discourse is full of asseverations and expressions respecting sacred things, often, however, used with a levity which it is difficult for a person unacquainted with their feelings easily to reconcile with their respect for God. They entertain an excessive reverence for their Prophet; and the Koran is treated with the utmost respect—never, for example, being placed in a low situation—and this is the case with everything they esteem holy. They are fatalists, and bear calamities with perfect resignation to the Divine will. Their filial piety and respect for the aged have been before mentioned, and benevolence and charity are conspicuous in their character; poverty is therefore not accompanied by the distressing circumstances which too frequently attend it in Europe. Humanity to dumb animals is another virtue, and cruelty is openly discountenanced in their streets, even to unclean animals. This is, however, unfortunately wearing off in consequence of their intercourse with Franks. Their affability, cheerfulness, and hospitality are remarkable, as well as frugality and temperance in food and drink, scrupulous cleanliness, a love of country, and honesty in the payment of debt. It should

be added, however, that the Egyptians rarely, if ever, exercise their social virtues but towards persons of their own persuasion and country. Their vices are indolence, obstinacy, and licentiousness, especially among the women, cupidity (mitigated by generosity), envy, a disregard for the truth, and a habit of cursing. Murders, and other grave crimes of this nature, are rarely committed, but petty thefts are very common.

"The Arabic spoken by the middle and higher classes in Cairo is generally inferior, in point of grammatical correctness and pronunciation, to the dialects of the Bedawees of Arabia, and of the inhabitants of the towns in their immediate vicinity, but much to be preferred to those of Syria, and still more to those of the Western Arabs" (Lane, *ibid.* ch. ix.). The language varies in Upper and Lower Egypt, and is more correct inland than near the Mediterranean.

In the decay of Arab literature, Cairo still holds the chief place as a seat of learning, and its university, the Azhar, is undoubtedly the first of the Eastern world. Its professors teach "grammatical inflexion and syntax, rhetoric, versification, logic, theology, the exposition of the *Kn-rân*, the Traditions of the Prophet, the complete science of jurisprudence, or rather of religious, moral, civil, and criminal law, which is chiefly founded on the *Kur-ân* and the Traditions, together with arithmetic as far as it is useful in matters of law. Lectures are also given on algebra, and on the calculations of the Mohammadan calendar, the times of prayer, &c." (Lane, *ibid.*). The students, as already remarked, pay no fees, and the professors receive no salaries. The latter maintain themselves by private teaching, and by copying manuscripts, and the former in the same manner, or by reciting the *Korân*. The students are now said to amount to the number of 11,000. Except the professors of literature, few Egyptians are taught more than to read and write; and of these, still fewer can read and write well. The women, as before mentioned, are very rarely taught even to read.

Science is but little studied, and barbers generally practise medicine and surgery. Mehemet Ali endeavoured to improve this state of things, by sending young men to Europe for the purpose of scientific study, and by establishing various schools, with the same object, in Egypt. His improvements have been continued by the present khedive, Ismail Pasha, with some success.

In common with other Muslims, those of Egypt have very many superstitions, some of which are peculiar to themselves. Tombs of saints abound, one or more being found in every town and village, and no traveller up the Nile can fail to remark how every prominent mountain has the sepulchre of its patron saint. The great saints of Egypt are the imâm Esh-Shâfe'ee, founder of the persuasion called after him, the seyyid Ahmad El-Bedawee, and the seyyid Ibrâheem Ed-Dasookee, both of whom were founders of orders of dervishes. The former of these two is buried at the town of Tanta, in the Delta, and his tomb attracts many thousands of visitors annually to his principal festival, the latter is also much revered, and his festival draws together, in like manner, great crowds to his birthplace, the town of Ed-Dasook. But, besides the graves of her native saints, Egypt boasts of those of several members of the Prophet's family; the tomb of the seyyideh Zeyneb, daughter of 'Alee, that of the seyyideh Sekeeneh, daughter of El-Hoseyn, and that of the seyyideh Nefeseeh, great-grand-daughter of El-Hasan, all of which are held in high veneration. The mosque of the Hasaneyn (or that of the "two Hasans") is the most revered shrine in the country, and is believed to contain the head of El-Hoseyn. As connected with the superstitious practices of Egypt, dervishes must be mentioned, of whom there are many orders found in that country, the following being the

most celebrated—(1) the Rifâ'eeyeh, and their sects the 'Ilwâneeyeh and Saadeeyeh; (2) the Kâdireeyeh, (3) the Ahmedeeyeh, or followers of the seyyid Ahmad El-Bedawee, and their sects the Beiyomeeyeh, Shaarâweeyeh, Shinnâweeyeh, and many others, and (4) the Barâhimeh, or followers of the seyyid Ibrâheem Ed-Dasookee. These are all presided over by a direct descendant of the caliph Abou-Bekr, called the Sheykh El-Bekree. The Saadeeyeh are the most famous for charming and eating live serpents, &c., and the 'Ilwâneeyeh for eating fire, glass, &c. The Egyptians firmly believe in the efficacy of charms, a belief which is associated with that in an omnipresent and overruling Providence. Thus the doors of houses are inscribed with sentences from the *Korân*, or the like, to preserve from the evil eye, or avert the dangers of an unlucky threshold; similar inscriptions may be observed over most shops, while almost every one carries some charm about his person. Among so superstitious a people, with whom, as we have already seen, science is in a very low state, it is not to be wondered that the so-called sciences of magic, astrology in the place of astronomy, and alchemy in that of chemistry, are in a comparatively flourishing condition.

Since the time of the Turkish conquest, the arts in Egypt have rapidly fallen into decay; this is partly attributable to the deportation of most of the skilled artificers of Cairo to Constantinople by the sultan Selim, but it is mainly owing to the misrule of the Turkish pashas, who have successively domineered over this unfortunate country. Cairo contains the most splendid specimens of Arab architecture of any part of the Arabian empire; but at present new buildings are erected after the Constantinopolitan model, or, what is still worse, the purely European—both styles immeasurably inferior to the Arab, and very ill suited to the requirements of the climate. In like manner, every other kind of native art is gradually perishing; and it is to be feared that even should the people be relieved from oppression and bad government, their industry will be encouraged rather to adopt imaginary improvements imported from Europe, than to cultivate the beautiful taste of their ancestors. The manufactures of the present inhabitants of Egypt are generally inferior to those of other Eastern nations, their handicrafts are clumsy, and the inevitable results of tyranny are everywhere evident; nevertheless, the curious shops, the markets of different trades (the shops of each trade being generally congregated in one street or district), the easy merchant sitting before his shop, the musical and quaint street-cries of the picturesque venders of fruit, sherbet, water, &c., with the ever-changing and many-coloured throng of passengers, all render the streets of Cairo a delightful study for the lover of Arab life, nowhere else to be seen in such perfection, or with so fine a background of magnificent buildings.

Among the luxurious habits of the Egyptians must be classed the immoderate use of tobacco (as before mentioned) and coffee. They are, however, rarely guilty of the vice of drunkenness, wine being prohibited by the *Korân*. Eaters of opium, and smokers of hemp, called hasheesh, are not uncommon, though they are always of the dregs of the people. The bath is a favorite resort of both sexes and all classes. In Cairo alone are upwards of sixty public baths, and every good house has a private bath. Their amusements are generally not of a violent kind, being rather in keeping with the sedentary habits of the people, and the heat of the climate. They are acquainted with chess, draughts, backgammon, and other games, among which is one peculiar to themselves, called Munkalah, and played with cowries. The game of the gered requires great bodily exertion; and wrestlers, &c., are found in the country, though not in any number. Music is the most favorite recreation

of the people of Egypt; the songs of the boatmen, the religious chants, and the cries in the streets are all musical. There are male and female musical performers; the former are both instrumental and vocal, the latter (called 'Almeh, pl. 'Awālim) generally vocal. The 'Awālim are, as their name ("learned") implies, generally accomplished women, and should not be confounded with the Ghawāzee, or dancing-girls. There are many kinds of musical instruments. The music, vocal and instrumental, is generally of little compass, and in the minor key; it is therefore plaintive, and strikes a European ear as somewhat monotonous, though often possessing a simple beauty, and the charm of antiquity, for there is little doubt that favourite airs have been handed down from remote ages. The prophet Mohammad condemned music, and its professors are in consequence lightly esteemed by the generality of Muslims, who nevertheless scruple not to enjoy their performances, and resort to the coffee-shops and to private festivities, where they are almost always to be found.

The Ghawāzee (sing. Ghāzeeyeh) form a separate class, very similar to the gypsies. They always intermarry among themselves only, and are all brought up to the venal profession. Their performances are too well known to need a description here, but it should be observed that the religious and learned Egyptians hold them to be improper. They dance in public, at fairs and religious festivals, and at private festivities, but not in respectable houses, whether before the men or the ladies. Mehmet Ali banished them to Isnā, in Upper Egypt; and the few that remained, occasionally dancing in Cairo, called themselves 'Awālim, to avoid punishment. A most objectionable class of male dancers also exists, who imitate the dances of the Ghawāzee, and dress in a kind of nondescript female attire. Not the least curious of the public performances are those of the serpent-charmers, who are generally Rifā'ee, or Saadee dervishes. Their power over serpents has been doubted by most European travellers, yet their performances remain unexplained; and apparently they possess means of ascertaining the haunts of these and other reptiles, and of alluring them forth; they, however, always extract the fangs of venomous serpents. Jugglers, rope-dancers, and farce-players must also be mentioned. In the principal coffee-shops of Cairo are to be found reciters of romances, surrounded by interested audiences. They are of three classes, and recite from several works, among which was formerly included the *Thousand and One Nights*; but manuscripts of the latter have become so rare as to render it almost impossible to obtain a copy.

The periodical public festivals are exceedingly interesting, and many of the remarkable observances with which they abound are passing away. The first ten days of the Mohammadan year are held to be blessed, and especially the tenth; and many curious and superstitious practices are observed on these days, particularly by the women. The tenth day, being the anniversary of the martyrdom of El-Hoseyn, the mosque of the Hasaneyn is thronged to excess, mostly by women. Following the order of the lunar year, the next festival is that of the Return of the Pilgrims, which is the occasion of great rejoicing, many having friends or relatives in the caravan. The Mahmal, a kind of covered litter, first originated by the celebrated queen Shoger-ed-Durr, is brought into the city in procession, though not with as much pomp as when it leaves with the pilgrims. These and other processions have lost much of their effect since the extinction of the Memlooks, and the gradual disuse of gorgeous dress for the retainers of the officers of state. A regiment of regular infantry makes but a sorry substitute for the splendid cavalcade of former times. The Birth of

the Prophet (Moolid en-Nebce), which is celebrated in the beginning of the third month, is the greatest festival of the whole year. During nine days and nights its religious ceremonies are observed at Cairo, in the open space called the Ezbekeeyeh. Next in time, and also in importance, is the Moolid El-Hasaneyn, commemorative of the birth of El-Hoseyn, and lasting fifteen days and nights; and at the same time is kept the Moolid of Es-Sūlih Eyyoob, the last king but one of the Eyyoobee dynasty. In the seventh month occur the Moolid of the seyyideh Zeyneb, and the commemoration of the Mearāg, or the Prophet's miraculous journey to heaven. Early in the tenth month (Shaabān), the Moolid of the imām Esh-Shāfe'ee is observed; and the night of the middle of that month has its peculiar customs, being held by the Muslims to be that on which the fate of all living is decided for the ensuing year. Then follows Ramadān, the month of abstinence, a severe trial to the faithful; and the Lesser Festival (El-'Eed es-Sagheer), which commences Showwāl, is hailed by them with delight. A few days after, the Kiswah, or new covering for the Kaabeh at Meccen, is taken in procession from the citadel, where it is always manufactured, to the mosque of the Hasaneyn to be completed; and, later, the caravan of pilgrims departs, when the grand procession of the Mahmal takes place. On the tenth day of the last month of the year, the Great Festival (El-'Eed el-Kebcer), or that of the Sacrifice, closes the calendar.

The rise of the Nile is naturally the occasion of annual customs, some of which are doubtless relics of antiquity; these are observed according to the Coptic year¹. The commencement of the rise is fixed to the night of the 11th of Ba-ooneh (Payni), the 17th of June, and is called that of the Drop (Loylet en-Nuktah), because a miraculous drop is then supposed to fall, and cause the swelling of the river. The real rise commences at Cairo about the summer solstice, or a few days later, and on about the 3d of July a crier in each district of the city begins to go his daily rounds, announcing, in a quaint chant, the increase of water in the Nilometer of the island of Er-Rōdah. When the river has risen 20 or 21 feet, he proclaims the Wofā en-Neel, "Completion" or "Abundance of the Nile." On the following day, the dam which closes the canal of Cairo is cut with much ceremony, and this is the signal for letting the inundation over the surface of the country. A pillar of earth before the dam is called the "Bride of the Nile," and Arab historians relate that this was substituted, at the Muslim conquest, for a virgin whom it was the custom annually to sacrifice, to ensure a plentiful inundation. A large boat, gaily decked out, representing that in which the victim used to be conveyed, is anchored near, and a gun on board is fired every quarter of an hour during the night. Rockets and other fireworks are also let off, but the best, strangely, after daybreak. The governor of Cairo attends the ceremony of cutting the dam, with the kádee and others. The crier continues his daily rounds, with his former chant, excepting on the Coptic New-Year's Day, when the cry of the Wofā is repeated, until the Saleeb, or Discovery of the Cross, the 26th or 27th of September, at which period, the river having attained its greatest height, he concludes his annual employment with another chant, and presents to each house some limes and other fruit, and dry humps of Nile mud.

¹ It may be mentioned here that the period of the hot winds, called the Khamāseen, that is, "The Fifties," is calculated from the day after the Coptic Easter, and terminates on the day of Pentecost, and that the Muslims observe the Wednesday preceding this period, called "Job's Wednesday," as well as its first day, when many go into the country from Cairo, "to smell the air." This day is hence called Sheem en-Neseem, or "the smelling of the zephyr." The 'Ulema observe the same custom on the first three days of the spring quarter.

This brief account of the modern Egyptians would be incomplete without a few words concerning the rites attendant on death. The corpse is immediately turned towards Mecca, and the females of the household, assisted by hired mourners, commence their peculiar wailing, while fikees recite portions of the Korán. The funeral takes place on the day of the death, if that happen in the morning; otherwise on the next day. The corpse, having been washed and shrouded, is placed in an open bier, covered with a cashmere shawl, in the case of a man, or in a closed bier, having a post in front, on which are placed female ornaments, in that of a woman or child. The funeral procession is headed by men called "Yemeneeyeh," chanting the profession of the faith, followed by male friends of the deceased, and a party of schoolboys, also chanting, generally from a poem descriptive of the latter state. Then follows the bier, borne on the shoulders of friends, who are relieved by the passers-by, such an act being deemed highly meritorious. On the way to the cemetery the corpse is generally, in Cairo, in the case of the northern quarters of the city, carried either to the Hasaneyn, or, if the deceased be one of the 'Ulemà, to the Azhar; or, in the case of the southern quarters, to the seyyideh Zeyneb, or some other revered mosque. Here the funeral service is performed by the imám, or minister of the mosque, and the procession then proceeds to the tomb. In the burials of the rich, water and bread are distributed to the poor at the grave, and sometimes a buffalo or several buffaloes are slaughtered there, and the flesh given away. The tomb is always a vault, surmounted by an oblong stone monument, with a stele at the head and feet, and a cupola, supported by four walls, covers the whole in the case of sheykhs' tombs and those of the wealthy. During the night following the interment, called the Night of Desolation, or that of Solitude, the soul being believed to remain with the body that one night, fikees are engaged at the house of the deceased to recite various portions of the Korán, and, commonly, to repeat the first clause of the profession of the faith, "There is no deity but God," three thousand times. The women alone put on mourning attire, by dyeing their veils, shirts, &c., dark blue, with indigo, and they stain their hands, and smear the walls, with the same colour. Everything in the house is also turned upside down. The latter customs are not, however, observed on the death of an old man. At certain periods after the burial, a khatmeh, or recitation of the whole of the Korán, is performed, and the tomb is visited by the female relations and friends of the deceased. The women of the felláheen (or peasants) of Upper Egypt observe some strange dances, &c., at funerals, which must be regarded as partly relics of ancient Egyptian customs.

For further information see, in addition to Lane's *Modern Egyptians*, his translation of the *Thousand and One Nights*, and particularly the notes to it, and the *Englishwoman in Egypt*, by Mrs Poole.

The native Christians of Egypt, or Copts, are chiefly descended from the ancient Egyptian race, and, as they rarely marry with other races, they preserve in their countenances a great resemblance to the representations of the tombs and temples. Their dress and customs are very similar to those of the Muslim Egyptians, but their reserve towards persons of another persuasion renders a knowledge of their peculiar observances exceedingly difficult. The causes which produced the separation of their church, and the persecutions they suffered, will be noticed in the historical portion of this article. Under Mehemet Ali they were relieved of much oppression, and the immunities then granted to them they still enjoy. The neglected appearance of their houses, and their want of personal cleanliness, are in strong contrast to the opposite habits of the Muslims, and

European residents generally prefer the latter as domestic servants.

The Jews, of whom there have always been great numbers in Egypt, appear to be even more degraded there than in other countries. They are held in the utmost abhorrence by the dominant race, and often are treated with much cruelty and oppression. Many are bankers and money-changers, &c. The quarter of the Jews in Cairo is exceedingly filthy, and would give a stranger the notion that they labour under great poverty. But such is not the case; the fear of the Muslims induces them to adopt this outward show of misery, while the interiors of many of their houses are very handsome and luxurious. (E. S. P.—S. L. P.)]

CHRONOLOGY AND HISTORY.

Before giving a sketch of the history of Egypt it is necessary to speak of Egyptian chronology. The difficulty of this subject has increased with the new information of the monuments. The statements of ancient writers were easily reconciled with half knowledge, but better information shows discrepancies which are in most instances beyond all present hope of solution. It may be said that we know something of the outlines of the technical part of Egyptian chronology, but its historical part is in a great measure mere conjecture before the times when we can check the Egyptian lists by their synchronisms with Hebrew and Assyrian history.

Dr Brugsch, in the second edition of his *Histoire d'Égypte*, frankly admits the growing difficulty of Egyptian chronology in terms which account for his not having continued his *Matériaux pour servir à la reconstruction du Calendrier*, the opinions of which are modified in the later work. Baron Bunsen completed his *Egypt's Place*, but in the progress of the work made a great change in his theories. Professor Lepsius alone has maintained his views, as stated in the *Chronologie* and *Konigsbuch*, of which the general correctness has not been disproved, although in any new work it would be necessary greatly to modify the details. The words, already referred to, of Dr Brugsch, which close the introduction to his *History* (2d ed.), may be cited in justification of the differences between the present article and that of the last edition of the *Encyclopædia*. "En comparant cette édition avec la première, le lecteur impartial reconnaîtra facilement que nous avons remanié complètement le premier travail, et de plus, que nous nous sommes abstenu de fournir des hypothèses auxquelles seulement le temps et des découvertes futures pourront substituer les faits" (p. 3).

The Egyptians divided the civil day into 24 hours, 12 of the natural day and 12 of the night, counted from 1 to 12 during each period. Ordinarily the civil day began during the night, which was indifferently reckoned as belonging to the preceding or following day. Probably the beginning was at midnight. In the astronomical tables of the Tombs of the Kings the civil day probably begins with the night, and the reckoning is from the first hour, or six hours before midnight. The indication is, however, not conclusive, as the tables are of nights only, but one term used makes it highly probable (Brugsch, *Matériaux*, 103). We also find the so-called heliacal rising of Sothis indicated as marking the beginning of the New Year, but this may merely denote that the phenomenon characterized New Year's day of the original Egyptian year, or of the fixed year, not that the civil day began with the 11th hour of night (cf. *Id.*, 90 seqq., Ideler, *Handbuch der Chronologie*, 1. 100-102).

The Egyptian month was of thirty days. The months are usually known by Greek names occurring in Greek documents, which were taken from the cultus connected with the months, and are thus the Egyptian sacred names. They are 1 Thoth, 2 Phaophi, 3 Athyr, 4 Choiak, 5 Tybi, 6 Meehir, 7 Phamenoth, 8 Pharmuthi, 9 Pachon, 10 Payni, 11 Epiphi, 12 Mesori, after which came the five Epagomenæ. The names were applied to the Vague and Alexandrian years. The ancient Egyptians had a different system of names. With them the months were allotted to three great seasons of four months each, of which the months were called 1st, 2nd, 3rd, and 4th. These seasons are called "sha," inundation, "per," winter, and "shema" summer. The second and third

renderings are undoubted, the first, which is that of Dr Brugsch, is not certain. If, however, it was so, we should have a difficulty in deciding to exactly which four months each season applied. It may be remarked that, according to the Copts, there are four months from the supposed beginning of the rise of the Nile, a few days before the summer solstice, to the end of the inundation. If this were the ancient reckoning, and the rendering "inundation" be correct, "winter" would be the cold season, and "summer" would correspond to spring and early summer. In support of this hypothesis it may be observed that the so-called heliacal rising of Sothis on the 20th of July marked the beginning of the Egyptian year, although in the year commonly in use this phenomenon passed through all the seasons, and further that in the earliest times of Egyptian history this phenomenon occurred about the time of the summer solstice, and the conventional beginning of the rise of the Nile, the three phenomena probably marking the beginning of the first season when the calendar was instituted¹ (cf. on the seasons, Brugsch, *Matériaux*, 34 seqq.).

The common year of the ancient Egyptians is that which has been called the Vague Year, because on account of its length of 365 days it fell short of a tropical or a sidereal year, and thus passed through all the seasons. That this year was that in which the inscriptions are usually dated before the introduction of the Alexandrian year under Augustus appears from the Decree of Canopus (Hierog. I 18, Greek I. 36, 37).

The Egyptians also used a fixed year dated from the so-called heliacal rising of Sothis, July 20. It contained 365 days, and was adjusted by the addition of another day for every four years. It is uncertain how far back this year was in use. The Calendar of Medinet Haboo, of the time of Ramses III., begins with the rising of Sothis, or, if we accept Dr Brugsch's explanation, with its festival (*Matériaux*, p. 84). Perhaps at the time of this monument the phenomenon fell on the 1st Thoth of the vague year, or within the month; or if the festival be intended, it may be used as a conventional indication of New Year's day in a typical form (*Ibid.* p. 84, 85). In the Roman period, after the Alexandrian year had come into use, there are double dates in the Alexandrian and Sothiac calendars, but the common Egyptian notation of the months does not appear to have been usually applied to the Sothiac year. An exception is noticed by Dr Brugsch (*Ibid.* p. 93), and another instance in which the month-name Tybi appears to be used for the Sothiac calendar, while an Alexandrian name is employed for the corresponding month of the Alexandrian calendar (*Ibid.* p. 92, 17. See on the whole subject, Brugsch, *Matériaux*).

The inconvenience of the vague year in relation to the festivals, on account of their connection with natural phenomena, led Ptolemy III. Euergetes to reform the calendar by intercalating a day after every fourth year before the year next following (Decree of Canopus, Hierog. I 22, Greek I. 43-45). Obviously this arrest of the common year was more convenient than the change to a fixed year already in use beginning at a different season. This new style was abandoned and the old resumed, but how soon we do not know.

Under Augustus a fixed year, called the Alexandrian, beginning on the 29-30th August of the Julian year, superseded the vague year. According to Lepsius, the Era of Augustus at Alexandria dated B.C. 30, but the first year of the new calendar, proleptically, B.C. 26, when the 1st Thoth vague corresponded to 30th August of the proleptic year of Augustus. The new reckoning, however, in his opinion could not have been introduced before B.C. 8, and was probably introduced A.D. 5. (See Lepsius, *Ueber einige Berührungspunkte der Ägyptischen, Griechischen, und Römischen Chronologie*, Berl. Akad., 1859). Although it is quite possible that Augustus adopted a proleptic synchronism of the Egyptian and Roman years for the official Egyptian year, thus dating back his reform, yet it is more probable that there was some special reason for choosing the particular Egyptian year selected, which, moreover, was not the first of the Era of Augustus. Brugsch has put forward a theory, which is the more remarkable in its bearing on this question as it is of wholly independent origin. He has shown reasons for supposing that a year beginning on the 25-29th August was in use in Egypt from the time of Dynasty VI. It must be admitted that many of his correspondences are of the Roman period, and therefore probably refer to the Alexandrian year; but others cannot be so explained, and it seems probable that the year which under Augustus superseded the vague year was already in use long before (*Matériaux*, p. 17 seq.). The Alexandrian year superseded the vague year, and has remained in use to our times, never having been wholly supplanted by the lunar year of the Arabs; but it has now given way to the Gregorian calendar.

At the time of Dynasty XII. the Egyptians used four years. These Dr Brugsch holds to be the vague year, a solar year, a lunar year, and a lunar year with an intercalation (*Hist.*, 2nd ed. 98-99). The second of these years no doubt was the Sothiac, the

beginning of which had an original connection with the summer solstice, and the duration of which was probably the Egyptian measure of a solar year. The lunar years would seem to be true lunar years, if we are to accept M. Gensler's theory that the Egyptians had discovered a method of adjusting their solar calendar with a lunar year by the intercalation of a month eleven times in thirty years (*Id.* 73). That the Egyptians at a later time used four years is evident from the Calendar of Isné, in which three beginnings are mentioned, that which stands at the head of the document and is of the Sothiac year, a beginning of the "year of the documents" on the 9th of Thoth, and another New Year's day on the 26th of Pryn (Brugsch, *Matériaux*, 19-22). This calendar is attributed by Lepsius to the reign of Claudius, but Brugsch can only decide that it is of the Roman period (*Id.* 88, cf. 22). If it is much later than the time fixed by Lepsius, the second commencement may be of the vague year, which began July 28 in A.D. 101-104. It is not probable that it is earlier than the introduction of the Alexandrian year, which, however, is unnoticed. Thus at least four years were probably in use in Egypt under the Romans.

No Era has been found in the Egyptian inscriptions. They always, if they date at all, date by the year of the reigning sovereign. There is but one instance of a reckoning of the nature of an era. It is the statement of the interval between two distant reigns in the stele in which, under Ramses II., an interval of four hundred years after a Shepherd king is mentioned, or more strictly, following the analogy of ordinary dates, the 400th year of the earlier king, as though he were still living. This, however, is not a strictly Egyptian document (*Records of the Past*, iv. 36). Similarly the coins of the Ptolemies, except one class, present no era, even those bearing the name of Ptolemy Soter, struck in Palestine and Phoenicia under Ptolemy Philadelphus and Ptolemy Euergetes, are dated by the regnal years of the kings who struck them. There are indeed coins dated by an era, probably struck at some town of Phoenicia, but these follow a foreign usage which otherwise is not found in the foreign coinage of the Ptolemies. It is therefore not surprising that the Egyptian cycles mentioned by ancient writers are not traceable on the monuments. One of these, the Sothiac cycle, consisting of 1460 Sothiac and 1461 vague years, or the period in which the vague year passed through one Sothiac year, was probably used by the astronomers, but we have no indication of its having been known earlier than the first century B.C., when Geminus writes that the Egyptian festivals pass through the whole year in 1460 years (*Isag.*, c. 6, Petavi, *Urano-logium*, 33). Censorinus fixes the beginning of a Sothiac cycle in A.D. 138 (c. 21), in the third vague year or second Alexandrian of the reign of Antoninus Pius. Curiously the Alexandrian coin commemorating in a symbolic manner this event is of the sixth year of this emperor. Theon, writing during the cycle beginning A.D. 139, speaks of the previous period as the Era of Menophres (ap. Biot, *Rech. sur plus p. de l'astr.*, p. 181 seq., 303 seq., *Sur la période Soth.* 18, 129 seq.). It is therefore generally supposed that a cycle beginning B.C. 1322 commenced in the reign of a Menptah, usually identified with the king of that name of Dynasty XIX. This is possible but not certain. Other cycles rest on less distinct evidence, and for the present we must be content to accept Brugsch's cautious judgment on the whole subject.

The historical chronology of ancient Egypt is less obscure than the technical is even fuller of difficulty. Our chief authorities are—(1) the Egyptian historian Manetho, who gave a list of thirty dynasties, and the length of each, with in some cases the duration of the individual reigns, (2) the similar list of the Turin Papyrus of Kings, and (3) various data of the monuments. Manetho's list is unhappily in a very corrupt condition. It appears, however, that his method is generally not strictly chronological. As far as we know, he makes up the sum of each dynasty, except Dynasty XII., of the individual reigns, where these are stated, taking no account of the overlapping of some of them. He seems to have given larger sums in three great groups. These again are made up of the sums of dynasties, and if any were in part or wholly contemporary, they are treated as successive. According to Syncellus, he stated the duration of the dynasties to be 3555 years. If this number, which suspiciously enough is given apart from the dynasty he came down correctly to the Byzantine chronographer, many hundred years must be cut off from the totals of the dynasties as they now stand for contemporary dynasties or kings. The Turin Papyrus is unfortunately in a far worse state than Manetho's list, but it is valuable as confirming and correcting it. The system of reckoning seems, however, to have been more strictly chronological than Manetho's usual method. The various data of the monuments are of yet of little value beyond affording evidence that Manetho's numbers

¹ If the agreement of the sidereal and tropical phenomena marked the institution of the year, a very remote date would be needed, but we cannot tell how early accurate the earliest observations were, nor do we know where they were made, and this in the case of the rising of Sothis is an additional element of uncertainty.

must be redneed, and as supplying fragments of historical chronology which may ultimately be united into a complete system. It has indeed been supposed that they enable us to construct an approximate chronology on genealogical evidence. This system, however, breaks down where we can test it, and it is therefore dangerous where it must stand alone. The great genealogy of the official arcln- tects gives 21 generations from the contemporary of Setee I. (Dynasty XIX 2), to the contemporary of Darius I (XXVII. 3); and thus, allowing three generations to a century, we should bring the birth of Setee and the beginning of Dynasty XIX to about B.C. 1200.¹ It is, however, quite certain that, reckoning from the synchronism of Sheshonk I., or Shishak, with Rehoboam, we must allow for the intervening period at least a century more. The historical events require this. We must therefore suppose that generations, either of heiresses or of other persons who did not hold the office of architect, are dropped. If this method of computing by genealogies thus fails where we have a genealogical list, obviously it cannot be applied to dynastic lists which we do not know to be genealogical. The average length of reigns is usually different from and less than that of generations, and we cannot tell the most probable average length of reigns without knowing the law of succession of the country, and its political conditions in the period under consideration. It is therefore especially hazardous thus to measure the Egyptian chronology before Dynasty XVIII, at which time ascending genealogical evidence fails us (See, however, Brugsch, *Hist.*, 2 ed. 25-27.)

The preceding observations will prepare the reader to find in the following pages no definite chronological system for the period before the synchronism of Egyptian and Hebrew history at the beginning of Dynasty XXII. The essay would, however, be incomplete without a short account of the chronological views of the leading Egyptologists. M. Mariette accepts Manetho's numbers with some modifications, and makes all the dynasties but one consecutive. He thus dates the beginning of Dynasty I B.C. 5004. Dr Brugsch, following the genealogical method, proposed by Prof Lieblein, and treating the reigns of the Tablet of Abydos as generations, but making an exception for the distracted age of the XIII-XVII. Dynasties, when he adopts a series of years derived from Manetho, places the beginning of Egyptian history at B.C. 4400² (*Hist.*, 2d ed. 170). Professor Lepsius adopts the 3555 years as the true duration of the thirty dynasties, and thus lowers the date in question to B.C. 3892. He reduces the length of the dynasties by making some in part or in whole contemporary.³ M. Chabas proposes with much hesitation the 40th century B.C. (*Études sur l'Antiquité Historique*, 2 ed. 15, 16). The following table gives the date of the beginning of each dynasty according to M. Mariette and Professor Lepsius. The less definite schemes of Dr Brugsch and M. Chabas cannot be tabulated in the same manner.

	M. Mariette.	Prof. Lepsius.	
Dynasty I	B.C. 5004	B.C. 3892	
II	4751	3639	
III	4440	3338	
IV	4295	3124	
V	3951	2840	
VI	3703	2744	
VII	3500	2592	
VIII	3500	2522	
IX.	3358	2074	
X.	3249	2565	
XI	3064	2423	
XII	2851	2380	
XIII	2398	2136	
XIV	2398	2167	
XV		2101	
XVI	2214	1842	
XVII		1684	
XVIII	1703	1591	} XVIII of Mariette.
XIX	1462	1443	
XX	1288	1269	
XXI	1110	1091	
XXII	980	961	
XXIII	810	787	
XXIV	721	729	
XXV	715	716	
XXVI	665	685	
XXVII	627	625	
XXVIII	406	625	
XXIX	399	399	
XXX	378	378	
Second Persian Conquest	340	340	

¹ Dr Brugsch escapes this difficulty by adding to the genealogy the reigns of Dynasty XVIII (*Hist.*, 2 ed. 26) as generations, and as these reigns had a shorter average length than generations, he recovers lost time.

² The apparent disagreement of this date and that given p. 27 as the result of the genealogical method is due to the higher date given in the table cited above to the beginning of Dynasty XVIII on chronological data (for XVII. read XVIII. p. 180). The lower date of this epoch is due to the strictly genealogical method in the earlier statement, but it must be admitted that the difference is large.

³ It must be remarked that he modifies the numbers of Manetho where they can be tested by monumental evidence, but in the great periods for which that evidence fails he is forced to accept them as they have come down to us. This system is developed with much skill in the *Chronologie der Ägypter und Königsbuch der Ägypter*.

There are two weak points in all these systems. They rest to a greater or less degree upon numbers either occurring but once or due to a single authority. The sum of 3555 years, which is the foundation of Professor Lepsius's system, occurs in but a single passage, and the same is the case with the round number of 500 years adopted by Dr Brugsch for the doubtful period of Dynasties XIII-XVII; it is taken from Manetho's 511 years of the Shepherd dominion. How if both these numbers are corrupt? If they are not their escape is a marvel, considering to what authors and copyists we owe them. Again, the sums of most individual dynasties rest on Manetho's sole authority, and his lists are in a state which is at present hopeless. It is equally unfortunate that while certain dynasties are represented by monuments from which Manetho's lists can be verified, others have left little or no records. Thus we have no monuments of Dynasties I-III. until the close of the last. Then there is an abundance of monuments of Dynasties IV., V., VI. A blank follows without a monument that we can assign to Dynasties VII., VIII., IX., X. Records reappear under Dynasty XI., of Dynasty XII. they are abundant. Under Dynasty XIII. they become scanty, and of XIV., XV., XVI., XVII. there are but a few, which may be of XV., XVI., or XVII. We have therefore three blank periods, the age before known monuments, the interval of Dynasties VII.-X., and that of Dynasties XIII-XVII. It is significant that whereas M. Mariette's reckoning exceeds that of Professor Lepsius 1112 years in the whole sum of the thirty dynasties, the excess is no less than 966 years in the sums of Dynasties VII.-X. and XIII-XVII. Such a difference between two such great authorities is a proof of the want of even probability for solving this part of the problem. Dr Brugsch, in applying the genealogical method to the lists of the monuments for the first and second blanks, while he rejects it for the third, is manifestly unwary. The evidence of the Turin Papyrus proves that we must not apply any such method to the third blank. How do we know that it can be applied to the other two? It may be argued that Manetho's numbers for the reigns of the first blank are probable, but neither his lists nor the monuments throw any light on those of the second, to which, notwithstanding, Dr Brugsch allows no less a period than about 500 years. His system has also the special fault that it rests on the supposition that the Egyptian reigns are equivalent to generations, which, as already shown, is by no means proved.

In the following sketch of Egyptian history no dates before the Christian Era will be given until the beginning of Dynasty XVIII, when approximative chronology becomes possible. Where, however, we may reasonably conjecture the length of a particular part of history, this will be stated.

The traditional age in Egypt is extremely obscure. History begins with the First Dynasty. The earlier period with Manetho, who is supported by the Turin Papyrus, is mythological, the age of the divine reigns, an idea also traceable in the monuments which treat certain divinities as sovereigns. This age is held to be spoken of on the monuments as that of the Shesu-har, the servants, followers, or successors, of Horus, who, in mythology, aid him in his combats with Seth (Chabas, *Ant. Hist.*, 7, 8; Brugsch, *Hist.*, 2d ed. 23). Manetho completely divests the time of any historical character by making it cyclical. It might be supposed that the Egyptians had some idea of records actually dating from this age, if we could accept M. Chabas's reading of the Ptolemaic inscription relating to the plan of the temple of Dendarah, in which it is stated that the original plan was found in the time of Pepi, of Dynasty VI., in ancient characters on a skin of the time of the Shesu-har. It appears, however, from the context that this inscription was of the time of Khufu, of Dynasty IV., and consequently the parallel expression is merely used to denote remote antiquity (Dumichen, *Bauwerkunde der Tempelanlagen von Dendera*, 15, taf. xvi.; 18, 19, taf. xv., cf., on the other side, Chabas, *Ant. Hist.*, 2d ed. 7, 8).

Egyptian mythology has not been found to contain any allusion to a deluge, nor to have any connection with the Mosaic narrative in reference to the cosmogony and the early conditions of the human race. Similar terms have been pointed out, but the leading facts are wanting. Thus the Egyptian ideas of their prehistoric age have a strange isolation by the side of those of most other nations of remote civilization, which agree in one or more particulars with the narrative of Genesis. Discoveries may, however, modify this view.

In Egypt stone implements have been recently discovered. Owing, however, to the abundance of historical monuments, the prehistorical remains have scarcely received due attention. We do not yet know whether these implements were used by the Egyptians or by savage tribes who may have made incursions into their territory. We find, however, the use of flint arrow-heads in the historical period from the paintings at Beni-Hasan (Dynasty XII.).

It is impossible to conjecture the duration of the prehistoric age in Egypt. M. Chabas has proposed a space of 4000 years before the First Dynasty as sufficient for the development of the civilization which had already attained maturity in the time of the Fourth Dynasty (*Ant. Hist.*, 9, 10). We are, however, so entirely ignorant of the causes of this civilization, and so unable to decide how far it was native to the soil of Egypt, that it is safer to abstain from any attempt to compute a period of the length of which the historical Egyptians themselves do not appear to have had any idea.

With Menes, in Egyptian Mena, the "stable," the history of Egypt begins. It is true that Manetho states cautiously of his successors of the Second Dynasty certain things that are evidently legendary. This must be the natural result of a want of monumental evidence, and a consequent dependence on tradition. At present no monuments are known before the time of the last king of Dynasty III., and this may be the limit at which inscribed contemporary records began. It is, however, agreed by all Egyptologists that the founder of the Egyptian state is no legendary personage. All we know of him wears the air of history, and is consistent with the conditions in which a state would have been formed. Menes was of Thinis, in Upper Egypt, and consequently the first two dynasties are called Thinite. Thinis, or This, in Egyptian Teui, was perhaps only a quarter of the more famous Abydos. Certainly it was obscured by the near neighbourhood of the sacred city. Menes, having gained the sovereignty of Egypt, which probably before his time was divided into two states, founded the city of Memphis. In order to gain sufficient room for the site he changed the course of the Nile by constructing a dike, which turned the stream more to the east. M. Linant believes that this dyke is probably represented by that of Kusheish. The great temple of Ptah, at Memphis, was then founded; and there can be no doubt that the seat of government was, under Menes, or not much later, removed to the new city. Menes made laws and waged a successful war. After a long reign of sixty-two years he was killed by a hippopotamus. All this has a perfectly historical aspect. Only a legislator and warrior, and so a mighty hunter, could have set upon a stable basis the long-lasting fabric of Egyptian polity. The main qualities of the man who did this could not have been forgotten at Memphis, which was great and flourishing, the chief seat of Egyptian learning and wealth, before the close of the Third Dynasty. The reproach that Menes corrupted the primitive simplicity of the Egyptians is probably a perverted tradition, like that which changed the tyranny of Khufu and Khafra to impiety. In later times Menes was revered with other kings, but as far as we know had no special worship, a condition suitable to his historical character, now universally admitted.

Athothis, either Tota or Atot, the first or second successor of Menes, is related to have founded the palace at Memphis, and, being a physician, to have written anatomical books. A medical papyrus in the Museum of Berlin, composed under Ramses II. (Dynasty XIX.), curiously illustrates the second statement. It contains a portion said to have been copied from a very ancient papyrus discovered in the time of Hespiti, or Usaphaidos, a later king of the First Dynasty, and to have been subsequently taken to Senta, or

Sethenes, of the next line (Brugsch, *Hist.*, 2 ed., 42). Under Unephes, the fourth Thinite king, a great famine, the first recorded, ravaged Egypt. He is also said to have raised the pyramids near Kochoe. As Kakem is the monumental name of the part of the Memphite necropolis around the Serapeum, and north of the Pyramid of Steps of Sakkarah, Dr Brugsch and others are disposed to consider that pyramid, which is a very archaic structure among pyramids, to be here intended. The use of the plural "pyramids" by Manetho does not stand in the way of the identification, as we know a case in which a small pyramid was built at the same time as a large one. We do not know the original purpose of the monument. Under the early dynasties it was used as the burial-place of the bulls Apis. As, however, their worship was introduced under Dynasty II., it may have been at first a royal sepulchre, like all other pyramids of which we know the use. Under Semeupses, the seventh king of the dynasty, Manetho speaks of many wonders and a very great plague. Thus the two chief scourges of Egypt appear in this remote age, suggesting a large population, and consequently the length of the period preceding the accession of Menes.

With Boethos, or Bntan, the Second Dynasty begins. Manetho relates that in his time a great chasm opened at Bubastis and many perished. Frequent as volcanic shocks are in Egypt, it is long since an earthquake has been experienced in that country. There are, however, reasons, from the manner in which monuments have fallen and the records of earthquakes in Palestine in antiquity, for supposing that Egypt was anciently more subject to such calamities than in later times. The next king, Kamechos, Kakan, introduced the worship of the bulls Apis at Memphis, and Mnevis at Heliopolis, and of the Mendesian goat, and his name appears to commemorate these innovations, probably a necessary step owing to the increase of population, for animals locally worshipped were thus restricted in number. We also notice that already Heliopolis and Mendes, besides Thinis, Memphis, and Bubastis had been founded. Under the next king, whose name, Binothis, Baunmter, was probably commemorative of the new worship at Mendes, we read that a law was passed that women could hold the sovereign power. This might in a semi-barbarous condition be a relic of polyandry, but in Egypt the civilization of Dynasty IV. forbids such an explanation, and we must rather regard this new law as a proof of advancement. In consequence we find a few reigns of queens in the Egyptian lists, but only one of them, Sebek-neferura (Dynasty XII.), appears in those of the monuments. Succession through an heiress was, however, carefully respected, and it was perhaps for want of a son that Binothis made this edict. It may be chance, but Manetho calls each king of Dynasty I. after Menes, son of his predecessor, whereas under Dynasty II. he drops this characterization. Nothing more is told of this line but two marvels, that under Manetho's seventh king, Nephherches, the Nile was fabled to have flowed mixed with honey for eleven days, and that the eighth, Sesochris, was said to have had a height of 5 cubits and 3 palms, which is not improbably a confused account of a colossal statue.

The royal house now changed by the accession of Dynasty III., the first of Memphites. Manetho relates how, under its head, Necherophes or Necherochis, the Nebka of the monumental lists, the Libyans revolted from the Egyptians but returned to, their allegiance terrified by a sudden increase of the moon. It is useless to speculate on the character of the phenomenon which, unless it be legendary, was probably an eclipse: but the glimpse we thus obtain of an Egyptian dominion beyond the Nile valley at this remote age is most valuable. In Genesis the Lchabim, or Lubim, appear as a race kindred to the Egyptians. In the

Egyptian inscriptions they are called Rebu, or Lebu, and appear on early monuments as a dark people. Under the Empire they have Caucasian characteristics. The change was probably due to the great maritime migrations of the Pelasgic tribes, in which the Libyans had an important share. To the next king, Tosorthros, Manetho assigns the invention of building with hewn stones and cultivation of letters, and says that for his medical knowledge the Egyptians called him Æsculapius. If the Pyramid of Steps dates from an earlier king, the first statement must be qualified, though it is to be remarked that the difference of constructive skill between that monument, if so early, and the works of Dynasty IV., would almost justify the historian, and again the discovery of inscriptions of a less accurately ordered kind than those of Dynasty IV. may support the second statement; the third seems at variance with the Memphite worship of the Egyptian Æsculapius, Imhotep. On the monuments contemporary history begins with the last king the lists assign to this dynasty, Senoferu, probably Manetho's last but one, Sephuris. We may now take a retrospect of the age. It is in some respects curiously primitive in comparison with that which immediately follows it. Dr Brugsch has remarked the general absence in the kings' names of the name of Ra, afterwards essential to throne-names, which from the medallic character of some of these they seem to have been, and the equally general absence of the names of other gods, Ra occurring once in the three dynasties and Seker once. Again he has observed the somewhat plebeian aspect of these names, as proper to men who sternly ruled the masses. Mena is "the stable," he who resists, Tota, "he who strikes," Senta, "the terrible," Huni, "he who strikes." Senoferu is "the betterer." As "the striker of the peoples," for so he is called in his inscription at Wadec Maghârah, in the Sinaitic peninsula, he is a foreign conqueror.¹

From Senoferu, at the close of Dynasty III, to the end of Dynasty VI, we have a succession of contemporary monuments by which history can be reconstructed, not only in its political events, but in those details of the condition of the population which make an essential part of all real history. Under Senoferu we find great material prosperity, and the arts already in that condition of excellence which makes the Pyramid age in some respects the most remarkable in the annals of Egypt. We also find foreign conquest, not as in the time of the Empire for glory, but with the view of extending the Egyptian rule to countries whose products were valuable for the arts. It is thus that this Pharaoh is the earliest who has left a tablet in the Sinaitic peninsula, where perhaps he, as Dr Brugsch thinks, was the first to plant military colonies to protect the workers in the mines of copper and the valuable blue-stone called "maskat," and this idea is supported by his being afterwards worshipped there. He is also the first king whose pyramid is found with its special name on the monuments. Dr Brugsch thinks it is that now called the Pyramid of Meydoom, near which chapels of tombs bearing his name have been discovered, and a group consisting of two statues, remarkable as a splendid specimen of Egyptian archaic art. The subjects, it may be remarked, were usually buried near the pyramid of the reigning king. Senoferu the betterer left a good name as a beneficent king, and his worship was maintained until the Ptolemaic period.

Khufu, the Suphis I. of Manetho and Cheops of Hero-

¹ The chronological length of this first unknown period in the thirty dynasties cannot be determined. In the Turin Papyrus three durations of reigns are preserved. They are each less than Manetho's numbers of the same reigns, however we fit the two lists together. It is further remarkable that while the length of Dynasty I gives nearly a generation of 33½ years to each reign (253—8—31 6) that of Dynasty II gives almost exactly this average (302, Afr.—9—33 5; 297, Lus.—9—33).

dotus, immediately succeeds Senoferu in the lists of the monuments, so that he may be regarded as the legitimate head of Dynasty IV. The list of that dynasty is as follows:—Khufu, Ratatf, Khafra, Menkaura, Shepseskaf, corresponding to eight kings in Manetho, in whom also the order is different, Ratatf (Ratoises) following Menkaura (Mencheres), a natural consequence of the association in fame of the builders of the three most celebrated pyramids, Khufu, Khafra, and Menkaura.²

The age of the pyramid-builders is the most brilliant before the Empire. We can judge from the royal tombs of the magnificence of the kings, and from the sepulchres around of the wealth of the subjects. The construction of the pyramids has perhaps been unduly marvelled at: we should know in what other manner the kings employed the vast amount of manual labour at their disposal, if we would estimate how much they could have effected by it in pyramid-building in the long period of time for which they ruled. If the two reigns of Khufu and Khafra extended over more than a century and a quarter, we may measure what we know them to have done against the works of other states during a like interval, and the comparison reduces our wonder.

The regal power at this time seems to have been very strong. So at least may we infer from the phraseology of the inscriptions, and from the fact that the kings threw much, if not all, of the force of the nation into personal monuments for their own memorial. Never in later times is the royal tomb the chief object of the king's reign, or is he so completely detached from the welfare of Egypt. The pyramids with their priesthoods are proofs that then the Pharaoh was more positively worshipped than ever afterwards.

It must, however, be admitted that the great men whose tombs are planned around the pyramids enjoyed abundant wealth and ease. Their time was passed not in war or in state affairs, but in the management of large estates, probably royal gifts, and in superintending the handicrafts of their people, and giving no small share of their leisure to the pleasures of the chase, to hospitality, and to the enjoyment of musical performances. In the chapels of their tombs these occupations of everyday life are portrayed. There is no sign of war, no great military class. It is true that the common folk seem to have been very poor, but their life in that land of abundance is at least represented as happy. On the other hand, it is significant that the nobility include a large number of the royal family, and that the king is

² The numbers of Manetho are irreconcilable with those of the Turin Papyrus assigned by scholars to this period. There is evidence that they cannot be considered to be consecutive in the inscription which mentions a lady, a Queen Mortitets, as a great favourite of Senoferu and Khufu and attached to Khafra. M. de Rougé remarks that she must have been very old at the time of Khafra (*Six Prem. Dyn.*, 256 seqq.), but in the list of Manetho the intervening reigns (Ratoises 25, Suphis [II] 66) amount to 91 years. If we allow her to have been 14 years old at the end of the reign of Senoferu and to have lived a year into that of Khafra, her age would not be less than 106 years. This is very near the extreme limit of human life in the Egyptian inscriptions, 110 years, and it is based on the minimum of time possible in the case. The length of early kings' lives in the Turin Papyrus supports this view. Probably the reigns overlapped one another. This idea is supported by the two chief chambers in the Great Pyramid, which has already made M. de Rougé suspect that it was the tomb of two kings (*Id.* 261, note 1). A sound argument for the chronology of the time might be found in the size of the three chief pyramids. A pyramid was the great work of a king's reign, and it was so constructed that it might be continually increased in size and yet easily completed at any time. The Great Pyramid would indicate a reign of maximum duration, so, too, the Second, whereas the Third would, in its original size, mark a shorter time. By this method we should be induced to accept Manetho's numbers for Khufu, 63 years, and Khafra, 66, but to doubt the long reign of Menkaura, 63. It would be reasonable on the other evidence to make Ratatf contemporary with Khufu or Khafra.

not represented in the tombs, and when he is spoken of it is in terms of the most distant respect. Similarly there is an extraordinary reserve as to worship. Religious subjects are wanting, and the religious inscriptions are usually limited to the formula of dedication. The priesthood is already numerous, but it is connected with the service of the chapels of the pyramids. In the vast court a baneful bureaucratic class is already growing, in future to destroy the welfare of the people.

The reign of Khufu is principally marked by the building of the Great Pyramid. We learn from a curious inscription of a later date that he rebuilt the temple of Isis, near the Sphinx, carved out of the rock by some earlier king, and that he made a pyramid for the Princess Hent-sen in the same neighbourhood. The charge of impiety which the local tradition reported by Herodotus brings against Khufu thus fails, and the charge of tyranny associated with it, may be equally groundless. The cost of life in building the Great Pyramid can scarcely be compared with that of a long war under conditions resembling those of modern China. It should be noted that Khufu, as well as Khafra and Rataf, were still objects of worship under Dynasty XXVI. (Brugsch, *Hist.*, 2d ed 57, 58). The only record of foreign conquest is a tablet in the peninsula of Sinai, commemorating what was probably no more than a successful maintenance of the posts already there established to guard the mines.

The reign of Khafra is commemorated, like that of Khufu, by the royal sepulchre and the tombs of subjects. From the latter we are able to contradict the tradition of his hostility to the national religion, in which Herodotus associates him with Khufu. The most interesting remains of the time are the statues of this king found in a well near the Sphinx, into which they were probably thrown either by a foreign invader or by early Christians or by Arabs, rather than in a popular revolt after his death (*cf.*, however, Maspero, *Histoire Ancienne*, 73). A statue and a bust of Khafra from this find have been published by M. de Rougé (*Six Prem. Dyn.*, pl. iv. v.). Both are remarkable works, showing a naturalistic style that makes them far superior to later statues. The king's head is evidently a portrait, and the type is more Caucasian than the generality of later subjects.

Menkaura, or Mencheres, the Mycerinus of Herodotus, and the founder of the Third Pyramid, does not seem to have been specially revered in later times, in contradiction to the report of Herodotus. It is, however, interesting, in connection with the tradition of his support of religion, that the Egyptian *Ritual* speaks of its 64th chapter as found by Har-tot-ef, son of Mencheres, at Hermopolis Magna, when he made an inspection of the temples of Egypt, and brought as a precious document to the king (Brugsch, *Hist.*, 2d ed p. 59, 60). It would thus appear that the *Ritual* was not then completed, and Manetho's statement that Suphis I., Khufu, wrote the sacred book may be another hint as to its date. It may also be noticed that the queen of Khafra was priestess of Thoth (*Six Prem. Dyn.*, 277 *seqq.*), and a noble, probably son of Khafra, was high-priest of Thoth at Hermopolis, a dignity held by another prince in the same reign (*Id.* 280, 281).

The most interesting record of Menkaura is his wooden mummy-case, found by General Howard Vyse in the Third Pyramid. In the disappointing silence of those vast monuments, without a single ancient Egyptian writing save the graffiti of workmen and the inscriptions of native visitors, this solitary record of the time is the one authoritative voice from the royal sepulchres, and it tells us in its short archaic formula that the whole myth of Osiris in its relations to human destiny was already matured. The king

as Osiris has become divine and has vanquished his enemies (Brugsch, *Hist.*, 2d ed., 58, 59).

The next family, Dynasty V., continued to rule at Memphis.¹ Of its sovereigns we know but little. The last but one, Asa, is the first Pharaoh whom we know to have had two names, the throne-name as well as the ordinary one. To his son Ptah-hotep is assigned the ancient moral treatise already noticed in speaking of Egyptian literature, which is on the whole the best fruit of Egyptian thought that time has spared. The last king, Unas, varied the form of royal tombs, by constructing the great truncated pyramid now called Mastabat-Faraon, or Pharaoh's Seat, north of the Pyramids of Dahshoor. (*Id.* 67.)

The Sixth Dynasty was probably a family of a different part of Egypt.² It has left many records which indicate less centralization at Memphis than those of the earlier sovereigns, and mark the beginning of wars for predatory purposes and extension of territory. This change is accompanied by a less careful style of sculpture, and less pains in the excavation of the tombs, as though the Egyptians were gaining a larger horizon, or, it may be, exchanging religion for ambition. The interest of the dynasty centres in the undoubtedly long reign of Pepi, second or third king of the line, and the inscription of Unas. In this inscription we first read of great wars, and foreign conquered nations are spoken of by name. A military system had already begun, for we read how the king sent with Unas an officer and soldiers to transport a sarcophagus for the royal tomb from the quarries of Turā. A war is then undertaken against the nomads of the eastern desert—the Amu (Shemites?) and the Herusha, "those who are on the sand." An army is levied from the whole population of Upper and Lower Egypt, as though there were no military caste. Negroes are also enrolled from several countries mentioned by name, which must have been subject to Egypt, and are drilled by Egyptian officers, including priests. Unas is appointed general in chief. Five separate expeditions are conducted by him into the country of the Herusha. It seems an error to suppose that this nation were Arabs of the desert, for the Egyptian general cut down their vines and their fig-trees (?). Another expedition was conducted by water, against the same nation in a country called Takhoba? (De Rougé) or Terehba? (Brugsch), which M. de Rougé conjectures may be Arabia Petraea, or a part of Syria, remarking that it was near Egypt, for the expeditions seem to have been annual. The external activity of the reign of Pepi is also attested by a tablet at Wādee Maghārah, and his public works by many inscriptions, among which we must not omit the occurrence of his name at Tanis, and in the inscription relating to the building of the temple of Dendarah. He founded a city called the "City of Pepi" in Middle Egypt, which has wholly disappeared, and tombs of his time are found in various parts of the Nile valley. His pyramid, which, like Memphis, was called the "good station," Men-nofet, was probably at the ancient capital, and may be one of the two great pyramids of Dahshoor, which

¹ This Dynasty appears to have consisted of nine kings, who probably reigned nearly 200 years (Brugsch, *Hist.*, 1 ed., 288).

² Manetho assigns to Dynasty VI a duration of 203 years. The monumental lists, themselves in disaccord, the Turin Papyrus, and the contemporary inscription of Unas, show that Manetho's list is here hopelessly corrupted. Unas was in office under the immediate or second predecessor as well as under the immediate successor of Pepi, usually identified with Phlopi, to whom the Egyptian historian assigns a reign of 100 or possibly 114 years. M. de Rougé has seen this difficulty, and discussed without finally resolving it (*Six Prem. Dyn.*, 261 *seqq.*). M. Maspero has proposed a most ingenious restoration of the dynasty, on the idea that Neferkara is the long-lived Phlopi, and that his family-name must therefore have been Pepi (*Hist. Anc.*, 96). This conjecture seems to us to be confirmed by the name of the later Neferkara Pepi of the Tablet of Abydos being qualified by the title "seneb," as if to distinguish him from an earlier king of otherwise identical name.

are of later date than Dynasty IV., if we may judge from their structure, and both of which from their size imply reigns of the greatest prosperity and of long duration.

Pepi was succeeded by his son Merenra. The new king made Una governor of Upper Egypt, and employed him to bring blocks of granite from Elephantine for his pyramid, and in various other works of which the inscription already referred to gives most curious details. He was charged to obtain wood, which was provided by the prince of four Ethiopian nations already mentioned among those furnishing negroes to the great army of Pepi. We thus learn that tributary Ethiopia was ruled by a native prince or princes under the governor of Upper Egypt, who also had the power of establishing posts in the dependency. Una made four docks and timber-yards in Ethiopia for building boats, and attached a chapel to each. We may thus expect to find some record of Egyptian rule at this early time, long before the complete reduction of Lower Nubia, in territories far south, for the timber-growing country does not begin for some distance within the tropics.

Merenra was followed by his younger brother Neferkara, and, according to Manetho, the dynasty ended with the beautiful Queen Nitocris, whose name appears in the Turin Papyrus, but whose exact historical place is not certain. If she was buried in the Third Pyramid, of which Manetho, according to the copyists, makes her the builder, she enlarged the original work of Mencheres, and certainly no pyramid is so evidently not merely a double structure but one of double design. Nitocris is almost the only Egyptian whose historical character has been lost in a succession of legends. One version of her story is the most ancient form of that of Cinderella, in another, she still bewitched the Arab of the Middle Ages when he approached her pyramid (*cf.* Maspero, *Hist. Anc.*, 94).

With the later part of Dynasty VI. the second great chasm in Egyptian history begins, and we have no monuments to guide us until the time of Dynasty XI. According to Manetho, Dynasties VII. and VIII. were of Memphites, and IX. and X. of Heracleopolites, the Diospolite or Theban line comprising Dynasties XI., XII., and XIII. Whether the dynasties which intervened between the VIth and XIIth were contemporary or successive, and how much time they occupied, cannot yet be proved. In the Tablet of Abydos, a series of kings unknown from other monuments follows Dynasty VI., and precedes two kings of Dynasty XI. In the Chamber of Kings of El-Karnak other and earlier kings of Dynasty XI. are named, with curious indications that it was first but a local line. To the period of the earlier kings of Dynasty XI. belongs Entefaa, who reigned at least fifty years. It would appear that the Memphite kingdom waned, and that another line arose at Thebes, the house of the Entefs and Mentuhoteps. The power of these kings gradually increased, and at last one of them reunited under a single rule the whole of Egypt. (Maspero, *Hist. Anc.*, 98, 99.) Probably the Heracleopolite line, Dynasties IX., X., was a local house contemporary with the Memphites or Thebans, or both.

With Dynasty XII¹ the Theban line was firmly established over all Egypt. In the circumstances referred to in the "Instructions" of Amenemhat I., its first king, to his son Usurtesen I., we have a glimpse into the unquiet condition of the country when the line arose (*Id.*, 101). Similarly the custom of associating the heir apparent as king with his father, the peculiarity of this dynasty, indicates the dangers that then surrounded the throne (*cf.* *Id.*, 105).

It is to the grottoes of Bence-Hasan that we owe most of

¹ The length of Dynasty XII appears to have been 213 years 1 m. 24 d. (Lepsius, *Ueber die Zwölfte Aegyptische Königsdynastie*, Akad. Berl. 1853.)

our knowledge of the manners and arts of Egypt under Dynasty XII., and much of its history is there told in the memoirs of a family of governors under the first five kings of this house. No one can have examined these beautiful tombs without being struck by the advance in architecture which they show, and the evidence of prosperity and cultivation afforded by their paintings. The subjects resemble those of the tombs of the earlier dynasties, but there is a greater variety, partly due to a more luxurious condition of society, partly to a more flexible art. It is sufficiently evident that the preceding dynasty (XI.) cannot have been weak, and the country under its rule distracted. A time of prosperity must have preceded this bright period of Egyptian history.

Amenemhat I., probably a successful minister of an earlier king (Brugsch, *Hist.*, 2d ed., 79, 80, 84), had an active and prosperous reign, ruling like Pepi beyond Egypt to the south, and occupying himself in the construction of various monuments. As the head of a new line he paid special attention to the boundaries of territories, to the regulation of the inundation, and to the confirmation of hereditary governors (Bence-Hasan inscr., Brugsch, *Hist.*, 2d ed., 94, 95). A very curious view of the state of Egypt in his time is given us by the story of Saneha in a hieratic papyrus of the Berlin Museum (translated by M. Goodwin, in *Records of the Past*, vi. 131, *seqq.*). It is the history of an Egyptian who fled from the king and took refuge with a neighbouring prince, whose territory unhappily we cannot as yet determine, and after a long sojourn sought his sovereign's pardon and returned home to be taken into the favour of Amenemhat. The reception of the fugitive abroad, his home-sickness, and the kindness of the Pharaoh, who at the same time is described in terms of the most abject respect, form an interesting picture, and one remarkably illustrating several events in the history of Egypt.

Under Usurtesen I., the co-regent and successor of Amenemhat I., Egypt had reached its highest prosperity after the age of the pyramid-builders of Dynasty IV. The obelisk which still marks the site of Heliopolis, a fragment of a statue at Tanis, inscriptions on the rocks of the Sinaitic peninsula, and a stele from Wâdee Halfeh, recording foreign conquests in the south, now in the Naples Museum, attest the splendour of this reign. The records of private individuals are, however, its most instructive memorials. Mentuhotep has given us a picture of the power and status of an Egyptian prime minister, holding all or nearly all the functions of the members of a modern cabinet, a position singularly parallel to that of Joseph, to the detail that even great men bowed before him. To his stele we owe the information that he gained successes against the Asiatics, the Herusha, and the negroes. (Brugsch, *Hist.*, 2d ed., 91, *seqq.*)

Of Amenemhat II. and Usurtesen II., the next kings, there is little to relate but that Egypt continued to prosper. It was under Usurtesen III. that a great step in advance was made by the fixing of the boundaries of the Egyptian dominion beyond the Second Cataract, at Semneh and Kummeh, where this king built sanctuaries and fortresses, and placed great boundary-marks in the form of tablets. These in their inscriptions define the limits of the kingdom, and regulate the passage of negroes by the river (*Id.*, 102). Here and throughout Nubia, Usurtesen was worshipped in subsequent times. He had introduced a settled government into the country, which long after was virtually a part of Egypt rather than a dependency. His successor Amenemhat III. is chiefly famous for his great engineering works. That care which the first Amenemhat bestowed on the regulation of the inundation seems to have been the great object of his reign. The rocks of Semneh and Kummeh bear registers of the height of the Nile in several

years of his reign. His great enterprise, the most successful of its kind ever carried out in Egypt, was the construction of a vast artificial reservoir, Lake Moeris, in the province now called the Feiyoom, which received the waters of the Nile by a canal, and after the inundation spread them over the country. Its fisheries were also very valuable. Through the neglect of ages the site of Lake Moeris was forgotten until, in our time, M. Linant traced it. Near the lake, Amenemhat III. built the famous Labyrinth, of which the remains were discovered by Dr Lepsius during the Prussian Expedition to Egypt, and there raised a pyramid. The use of the Labyrinth is unknown; the pyramid was no doubt the royal tomb. Its moderate dimensions and the vast size of the lake show a remarkable contrast to the earlier great pyramids, with apparently no corresponding work of public usefulness. At the time which produced the Lake Moeris civilization had reached a point far above that of the age of Khufu, perhaps the highest Egypt has ever known. Of the short reigns of Amenemhat IV. and Queen Sobek-nefru-ra we know nothing, but that with the latter the dynasty came to a close.

With the accession of Dynasty XIII. we reach the third chasm in the Egyptian monumental records. This line, Theban like its predecessor, but with a special favour for Middle Egypt (*cf.* Brugsch, *Hist.*, 2d ed. 115), seems to have ruled all Egypt. Its power, however, was evidently weakened, either by external war or by internal dissension. Many monuments may have been lost or may yet lie hid in the mounds of towns of Middle Egypt, but the scantiness of records of public works is a proof of its weakness. Where are its tablets in the quarries? In the Turin Papyrus are preserved the lengths of several of the reigns of its kings, who generally bore the names Sobek-hotep or Nefar-hotep. The longest reign is 13 years, and but one other reaches 10, the total of 13 reigns being but 48 years 22 days, and 6 sums of months and 7 of days effaced. Putting the total at 50 years, the allowance for each reign is under 4 years. This must have been a time of disturbance, but not necessarily of disastrous wars; for if we compare the rule of the second line of Memphite sultans we obtain an average reign of 5 years each. This we know to have been the consequence of domestic disturbance, and not of great public disasters at home or abroad. Dynasty XIV., of Xoites, the next in Manetho's list, is the first which had certainly its capital in the Delta. Beyond this fact we can only conjecture its importance and chronological place.

The invasion and conquest, at least in part, of Egypt by the Hyksos, or Shepherd Kings, is undoubtedly the chief cause of the obscurity of this age. The event did not happen until at least some time after the beginning of Dynasty XIII., for the eighteenth king of that line in the Turin Papyrus, who bears the significant name Mer-mesha, "the general," has left a record at Tanis near the eastern frontier, which was probably the chief city of at least one dynasty of the invaders.

Manetho, as cited by Josephus, allows for the stay of the foreigners in Egypt a period of 511 years, which has been supposed to be about the interval between Dynasty XII. and Dynasty XVIII., by which they were expelled. This number, however, rests upon the single evidence of Josephus, and is moreover probably made up of sums of dynasties, which would render its evidence doubtful. A better means of measuring the period would be afforded by the monumental evidence that a Shepherd king ruled 400 years before Ramses II. could we place this foreign sovereign. All that can be said as to the chronology is that Dynasty XV. and XVI. were probably of Shepherds, and Dynasty XVII. was certainly Theban. Judging from the numbering, it is probable that there was a break in the

Theban succession, and that the two Shepherd dynasties were successive, the Xoites perhaps being but a provincial line.¹

The story of the Hyksos is thus told by Manetho. Under a king called Timaioi, or Timaos (not recognized in the list or on the monuments), certain invaders from the East conquered Egypt without a battle, destroying the temples and slaying or enslaving the people. At length they made one of themselves, Salatis by name, king, who ruled at Memphis, and made all Egypt tributary. For the better protection of the eastern border he rebuilt and fortified the city Avaris, in the Sethroite nome in Lower Egypt, where he kept a great force of soldiers. He was succeeded by other kings mentioned by name, who, and their descendants, held Egypt for 511 years. After this the kings of the Thebais and of the rest of Egypt rose against the Shepherd rule, and a great and long war was waged, until Misphragmuthosis drove the Shepherds out of all Egypt except Avaris, where his son Tuthmosis besieged them, and failing to take the place agreed to a capitulation, on the condition that they should be allowed to leave the country. Accordingly they went through the desert to Judæa and founded Jerusalem. They were called Hyksos, or Shepherd kings, and, according to some, they were Arabs.

This narrative, notwithstanding a general confirmation from the monuments, is evidently not wholly correct. In particular it is inconsistent with all other evidence in attributing the foundation of Jerusalem to the Shepherds, which is evidently the result of an endeavour to connect their departure with the Exodus. Manetho seems to have preserved two Egyptian theories of the Exodus, which both explained that event as the retreat of eastern invaders. M. Mariette's researches in the ruins of Tanis have brought to light monuments of the Shepherds, and led to the discovery of others elsewhere, while M. de Rougé and other scholars have explained Egyptian documents connected with the war of independence. From these different sources we learn that the foreigners were of the Shemite or a kindred type, resembling the modern inhabitants of the north-east of Lower Egypt, who still retain the peculiarities already noticed by Greek writers. Though their conquest may have been marked by violence, we find them in their own monuments using and cultivating the manners and civilization of Egypt, and even giving a new and characteristic development to its art in their costly monuments of granite, which show from their material that their rule extended to the southern boundary of Egypt. The war of independence arose between Apepee, one of their later kings, who is described as worshipping Seth only, and one of the three Theban kings called on the monuments Ra-skenen Taa, at this time apparently a tributary prince. The war, contrary to Manetho's statement, does not seem to have been of long continuance, having been brought to a successful end by Aahmes, first king of Dynasty XVIII., between whom and Ra-skenen Taa no great length of time can have elapsed. Manetho's text is again erroneous in making the conqueror Tuthmosis (Thothmes IV.), son (grandson) of Misphragmuthosis (Thothmes III.), sixth

¹ The Tablet of 400 Years states that this period elapsed from some point in the reign of the Shepherd king Set-aa-pelti Nub to some point in that of Ramses II., and again Apepee, whose name corresponds to the Apophis of Manetho, almost immediately preceded Dynasty XVIII. Apophis is mentioned among the only Shepherd kings Manetho names. In the passage preserved by Josephus these are called the first Shepherd rulers, who very properly compose the first Shepherd dynasty, the XVth, in the epitome of Africanus; though Eusebius transfers them to Dynasty XVII., perhaps knowing they immediately preceded Dynasty XVIII. In Africanus, Dynasty XVI. is of Shepherds and XVII. of Shepherds and Thebans. If the identification of Apepee with the Apophis of Dynasty XV. were certain we might have a rough measure of the time of the Shepherd rule, but this is not proved.

and fifth sovereigns of Dynasty XVIII. in his list; but this may be a confusion due to copyists, as there is other evidence that he placed the conquest of the Shepherds under Amosis, or Aahmes. The expulsion of the foreigners was not so complete as Manetho would have us imagine. Several names in their territory remained Shemito, or the population non-Egyptian, and under Dynasty XIX. the prejudice that appears in Dynasty XVIII. seems almost removed.

It must be here noticed that Dr Brugsch has copied a remarkable inscription, from the tomb at Elethyn of Baba, whom he assigns to the latter part of Dynasty XVII., in which mention is made of a famine of successive years. "A famine having broken out during many years, I gave corn to the town during each famine." There are but two known instances in history of a famine in Egypt lasting several years, the seven years' famine of Joseph and the seven years' famine of the Fâtîme caliph El-Mustansir. Dr Brugsch has, therefore, argued with high probability that Baba records the famine of Joseph, and that the old tradition that Joseph governed Egypt under the Shepherd King Apophis is a true one (*cf. supra*, p. 735, note 1). To this we shall recur in speaking of the Exodus. (See Brugsch, *Hist.*, 2 ed. 174, *seqq.*)

The beginning of Dynasty XVIII. (B.C. 1600-1500?) is marked by two great events, the union of divided Egypt under one head, and the victorious end of the great war with the Shepherds.¹ Aahmes, probably a Theban prince, appears to have secured the supreme rule over the various princes of Egypt, without abolishing their rights, and to have gained Ethiopian support by his marriage with Nefru-ari, daughter of a king of Ethiopia. He then directed his whole power to the final liberation of Egypt. The tomb at Elethyn of Aahmes son of Abuna, an officer of the Egyptian flotillas, in an inscription relating his services, throws light on the events of this war. He passed his early youth in the fortress of Elethyn, one of the strong positions where the kings of Dynasty XVII. rallied their subjects. In the reign of Aahmes he was made officer of the ship called the "Calf." Later he went to the flotilla of the north to fight. It was during the siege of the fortress of Avaris. He served in the vessel "Ruling in Memphis," a name no doubt given to commemorate the addition of the ancient capital to the dominions of Aahmes. An engagement took place on the water near Avaris. Subsequently Avaris was taken, and the young officer carried off three captives, whom the king granted him as slaves. This was in the fifth year of Aahmes, in the next we read of the conquest of Sharuhan, the Sharuhan of the book of Joshua, in the south-west of Palestine. The memoir then adds that, after having slain the Shepherds of Asia, the king undertook a successful expedition against an Ethiopian country (See Brugsch, *Hist.*, 1 ed. 80, 81.)

This narrative, while generally confirming Manetho's story, corrects it in some particulars. It states that Avaris was taken, not that it capitulated, and indicates a pursuit of the enemy within the territory of Palestine, where they were again conquered in a city which they attempted to hold. The Ethiopian expedition was a reassertion of the Egyptian dominion to the south. Two tablets in the Turâ quarries record how, in the twenty-second year of his reign, Aahmes restored the temples which had fallen into decay,

¹ The chronology of Dynasty XVIII. is not yet fixed. Manetho's list is here in a very corrupt state. Certain numbers can be corrected or confirmed by the monuments, and if we provisionally accept the others, we obtain a sum of not greatly over two hundred years for the line, supposing it to end with the accession of Ramses I. It must, however, be remembered that those numbers which are provisionally accepted are manifestly unsafe. The sum may be more nearly determined when we know the place of the Shepherd-king Nub, whose reign was 400 years before that of Ramses II.

the blocks being removed by bulls under the charge of Phœnicians? (Fenkhu) (Brugsch, *Hist.*, 2 ed. 173, 174). It may be recollected that the Phœnicians appear as skilled smiths and masons in the time of Solomon, and that as early as the Exodus they were already great metal-workers.

From the time of Aahmes till the close of Dynasty XX. we may reckon the rise, fulness, and decay of the Egyptian Empire. It is a period of abundant monuments, sculptured and painted, and of many papyri, rich in records of the history, manners, and religion of Egypt. The state of the country may be glanced at in this place, where the Shepherd period closes, so as not to break the continuity of the subsequent history.

The sudden growth of prosperity at home and power abroad which marks the early reigns of Dynasty XVIII. is truly surprising. The Egypt of Dynasty XVII. is broken up and only slowly reuniting; that of Dynasty XVIII. is at once solidly bound together, and soon to engage in designs of world-dominion never hinted at in earlier times. These conditions were the result of a great national war, in which the country discovered her hidden force, and was not content to use it only so far as was needful to make a strong Egypt like that of Dynasty XII. Having conquered her foreign rulers at home, she desired to add their native lands to her own dominions. The first effects of these designs were the enrichment of Egypt. In the early reigns of this house the wealth of the subjects as of the king rapidly grew. From the simple monuments of Dynasty XVII. and the first kings of Dynasty XVIII. there is a sudden advance to richness and splendour. Egypt was, however, becoming a military state. The king is constantly more powerful, and his public works more magnificent; the subjects, notwithstanding the luxury of individuals, have not that solid princely strength that we admire in those of the Pyramid kings and Dynasty XII. The appearance of the horse under this dynasty is most significant. The beasts of burden, the ox and ass, now yield in importance to the war-horse, and the landed proprietor journeys in his car whose ancestor went afoot staff in hand. Thus the military man succeeds the farmer. The priest is no longer a great man who has assumed sacerdotal functions, but one of a class immensely extended, reaching from the highest dignitaries, one of whom, strengthened by hereditary power, could at last seize the throne, down to the menial class who lived upon the superstitions of the people. To carry on the government there grew side by side with soldiers and priests a vast official body, clever, ambitious, and unscrupulous, which rapidly on the true bureaucratic principle involved the administration in an entanglement which must have mainly led to the decline of the Empire. Justice, which was difficult at home, must have been almost impossible abroad. We now cease to hear of hereditary nomarchs studying the welfare of provinces to which they were attached by ancestral connection. All posts went by the royal favour. The common people fared ill in this age. Their function was to supply soldiers for the army and navy, and at first to take their share in the construction of public works; their only hope was to rise in the official class. Handicrafts and all labour were beneath a gentleman; hence no one could rise to his grade but through success at the schools, which were open to every one, and where a boy of talent had his chance of a career (*cf. Brugsch, Hist.*, 1 ed. 16, 17).

Of the administration of provinces and conquered states we know little. Lower Ethiopia had always been ruled as a part of Egypt; this system was extended southward. At first the eastern states only paid tribute. Ultimately garrisons were placed in Palestine and Phœnicia (Brugsch, *Hist.*, 1 ed. 135). Compared with the Assyrians the

Egyptians were civilized conquerors, and the sculptures of their battles do not represent any scenes of extreme cruelty. They do not, however, seem to have known the art of effectually holding their acquisitions, which had to be reconquered over and over again, until the inevitable tide of conquest on the other side set in, and the Empire fell.

On examining the earliest monuments of Dynasty XVIII. we are startled by their astonishing resemblance to those of Dynasty XI., a resemblance which would, had we no historical evidence on the other side, justify the leap of the Tablet of Abydos from Dynasty XII. to XVIII. This may be partly explained as a renaissance of art due to a royal descent traced rather to Dynasty XI. than Dynasty XII. Similarly under Dynasty XXVI. there was a renaissance of the art of the age of the early Memphite Dynasties. We must also not lose sight of the local character of Egyptian art and its intense conservatism, which may have preserved an ancient type through many centuries. The early art of Dynasty XVIII. has this character of a survival; that of Dynasty XXVI. is clearly a modern imitation.

The art of this age is in some respects the finest Egypt produced; it is, perhaps, best about the time of Thothmes III. and Amenophis II., the middle of Dynasty XVIII. It is inferior in naturalism to the art of Dynasty IV., and in delicacy to that of Dynasty XII., but it has a certain splendour before wanting. After it had attained its highest point it slowly declined, partly from a decay in the vigour of the national character, perhaps more from the vast size of the later monuments, which must have led to a neglect of finish in the details, though this neglect can only be seen by one who is thoroughly acquainted with the Egyptian styles. At all times there is an invincible patience in the mastery of material and the execution of detail. The temples, not the kings' tombs, are now the largest and most costly edifices; though a compromise with the old idea is effected by making grand temples as sepulchral chapels in religious connection with the royal tombs, commemorating in their sculptures the events of the reigns. The tombs of subjects do not maintain the proportion the earlier ones hold to the royal sepulchres. Their paintings have less of daily life, and religion takes a greater and growing place on the walls. We have, however, a multitude of interesting scenes, which show us a life more luxurious in the many than that of earlier times, but not as splendid in the few. There is more of feasting, of music, and the dance, less of country life and the welfare of the retainers. The royal tombs are now grottoes deeply cut in the rock, and the pictures of their walls are religious, the historical part being left to the funeral temples.

Amenhotep or Amenophis I., son of Aahmes and his Ethiopian queen, carried on the Ethiopian wars. It is of his son, the next king, Thothmes I., that the great eastern campaigns are first recorded. He advanced as far as the Euphrates, and must therefore have subdued, or at least marched through, the greatest part of Phœnicia and Syria. The prosperity of Egypt at this time is shown by the splendid works he executed in the great temple of Amen-ra at Thebes, the earliest of their kind that we can trace, and apparently the beginning of the series which was only to cease with the fall of the Empire. The employment of captives in public works was the main means by which they could be carried out. Probably after a time all that Egypt could do was to furnish men for the army, and in even this she failed when the dynasty came to an end. Before his death Thothmes I. had associated with him on the throne his daughter Hatshepu, or Hatasu (Maspero, *Hist. Anc.*, 201), who succeeded him with her elder brother and husband Thothmes II. Her power is an evidence of the importance the

Egyptians attached to the female line. At the same time their dislike to be governed by a queen is evident in the attempt she subsequently made to assume the character of a king, being represented in male attire, a circumstance to which the monuments present no parallel.

After the seemingly uneventful reign of Thothmes II., Hatshepu was associated, apparently as regent, with her younger brother Thothmes III., and usurped the sole power. It is in this time that she appears as a king. She continued the works of the temple of Amen-ra, where the great obelisk and its fallen fellow bear her name. Her most interesting achievement was an expedition to Punt, either the Somálee country or Arabia Felix. She collected a fleet on the Red Sea, and herself commanded it. The people accepted her rule, and she brought back great tribute, including small spice-trees, which she planted at Thebes. The glimpse we thus gain into the state of the civilization of the spice-growing countries at this remote age is most valuable, and explains the facility with which the southern dominions of Egypt were held. The nations in this direction were not masses of barbarous tribes, but their civilization did not take the direction of the pursuits of war.

Hatshepu had reigned about twenty-one years when Thothmes III. succeeded her. He carefully effaced her name on the monuments, substituting that of his brother and his own, and reckoned his reign from her accession. Whether he thus included his brother's reign or not we do not know. With the sole reign of Thothmes III. a series of great expeditions begins, from the records of which we have great insight into the condition of Syria and Palestine about the 15th century B.C.

It will be well here to glance for a moment at the Egyptian geography of this territory. There is great difficulty in explaining it, probably due to the different names apparently given to the same countries and peoples at one and the same time or at different times. We may, however, gain somewhat in clearness by observing that more than one important geographical name can only be an Egyptian appellative. Thus the Shasu, who were wandering Arabs of the desert, who moved up as now into Palestine for pasturage or on predatory excursions, are nothing but "robbers." Most other names may be probably identified with Semitic equivalents. Syria is called Khal this word is connected with Syria by the late equivalent Asher (cf. Maspero, *Hist. Anc.*, 181, note 1), which shows that the Egyptians then identified Syria and Assyria. The great nation of Syria in the time of Thothmes III. was the Ruten. These may be the Shemites of the stock of Lnd, and may be also the Lydians in a primitive seat. Under Ramses II. the Kheta, a northern division of the Hittites, held the political position of the Ruten, as though the Ruten had migrated. As the Ruten probably represent the Aramæans, so the Hittites represent the Canaanites. The Phœnicians appear to be the Kefa; in the time of Thothmes III. they held an insular position in the Mediterranean, probably Cyprus, under Ptolemy III., they gave their name to Phœnicia. They are clearly the Biblical Caphtorim. The Philistines do not appear until the time of Ramses III. None of the primitive nations whom the Bible mentions as supplanted in the period before Joshua have been traced on the monuments, nor is there any clear notice before the time of Sheshonk I. (Shishak) of the Terahites. The period of Thothmes III. is one of Aramæan supremacy, that of Ramses II. of Canaanite; together they well correspond to the age before the Israelite conquest, while the condition of the time of Ramses III. suits the latest age of the Judges. The names of towns present less difficulty. Many are traceable in Biblical geography, and here but one indication occurs which may point to Israelite occupation.

The Egyptian conquests on the east being tributary, there were constant revolts on the accession of new sovereigns. It was thus that Thothmes III., on becoming sole ruler, had immediately to reduce the Ruten and their neighbours. This caused the series of eastern campaigns, which began in the twenty-second year, very early in his sole reign, and certainly extended to the forty-second, during which whole time there was seldom a year of repose. The history of these wars is told in the Annals of Thothmes III., which contrast favourably with those of the Assyrian kings.

If they were marked by barbarity, there is no boast of ought but conquest and the levying of tribute. The tribute no less than a contemporary painting shows the great material civilization of the Asiatic states. Throughout, the Ruten are the most formidable enemies; the Kheta only appear. The first great achievement was the defeat before Megiddo of a confederacy led by the prince of Ketesh, or Kadesh on the Orontes. In the battle only 83 of the enemy were killed, and 340 taken prisoners; but the magnitude of the success is proved by the capture of 2232 horses, 924 chariots, and the speedy surrender of Megiddo. This town, as in Josiah's time, was the key of the route to the Euphrates, and on its capture the king of the Ruten and the king of Assur are mentioned as becoming tributaries. In the course of the wars Kadesh was captured twice, and the king of Egypt marched as far as Nineveh, and the name of Babel is mentioned. The reign of Thothmes was also marked by expeditions in Ethiopia, and then we first meet with the supposed Egyptian name of the Dauai, with whom he came in contact during some expedition in the Mediterranean. Great buildings commemorate this active reign, and we have a glimpse of the personal character of the king in the eccentric architecture of one of his additions to the temple of Amen-ra at Thebes. After a reign of 54 years 11 months, reckoning from the accession of Hatshepu, Thothmes III. was succeeded by his son Amenophis II.

The accession of the new king was marked by a war in Assyria, in which he captured Nineveh. An incident of his eastern campaigns is remarkable for its Oriental barbarism. He brought back to Egypt the bodies of seven kings whom he had slain with his own hands. The heads of six were placed on the walls of Thebes; the seventh was sent to remote Napata in Ethiopia to be hung on the walls to strike terror into the negroes. After a prosperous but probably short reign, Amenophis II. was succeeded by his son Thothmes IV., of whom we only know that he maintained his father's empire during a reign that probably did not exceed the nine years assigned to him by Manetho.

Amenophis III. succeeded his father, and, during a long and it seems mainly pacific reign, occupied himself in great architectural works. Two temples at Thebes owe their origin to him, that on the western bank, which was the funeral temple of his tomb in the western valley beyond, and of which little now remains but the two great statues in the plain, the Vocal Memnon and its fellow, and also the temple of El-Uksur on the eastern bank. In his time the dimensions of the structures of the earlier kings are surpassed, and the proportions of the greatest monuments of the Empire are almost attained. Probably he was the first of the family after Aahmes who took a foreigner to wife. On the great scarabæi which commemorate his marriage with Queen Tai, we are informed that his rule extended from Mesopotamia to Southern Ethiopia.

Amenophis IV., the son of this foreign marriage, is the most perplexing character in ancient Egyptian history. Under his mother's influence he introduced a new religion, the worship of Aten, the solar disk, and after a time wholly suppressed the national religion, even changing his name to Khn-n-aten. Abandoning Thebes as the capital, he founded a new city in Middle Egypt, where he constructed a chief temple to Aten, and near which his officials excavated their tombs in the mountain. The type under which the king and his family and subjects are represented is unlike any other in Egyptian art. They are all of emaciated and distended figure, and surpassing ugliness. The king is treated with a servile respect nowhere else seen on the monuments. His troops are mixed with foreign mercenaries. But we do not hear of foreign expeditions; every one is occupied in the duties of the new religion, without polytheism or idols. Flowers are the chief offerings and adorn the

temple throughout; hymns chanted to the sound of harps are the form of worship. Was this a foreign religion, or an Egyptian restoration of primitive belief? If it were Egyptian why was the sun called Aten, not Ra? The king was the son of a foreigner, and his type and that which marks his court, probably because some were of his mother's race, and art assumed the fashionable type for the rest, is not recognizable in any of the characteristic representations of foreign races. It is neither Ethiopian nor Shemite nor Libyan. The names of his mother and of her parents, the name of the sun-god, which is Egyptian, and the character of the worship, do not as far as we know point to any of these races. Certainly they are not Semitic. For race and religion we must probably look beyond the horizon of the Egyptian conquests. The type is not without an Indian aspect, and the religion has in its simplicity and the character of its worship a striking likeness to Vedism.

Khn-n-aten had seven daughters and no son. His successor Ai was his foster-brother and the husband of his eldest daughter. Under him the national religion was tolerated. Two other sons-in-law succeeded. Their line then or soon after came to an end, on the accession of Har-em-heb, or Horus, who claimed to be the legitimate successor of Amenophis III., either by descent or on account of the innovations of Khn-n-aten, who with the kindred kings does not appear in the monumental lists, in which Har-em-heb is seen as the immediate successor of Amenophis III. The same order is followed in Manetho's list, in which the house of Khn-n-aten follows Horus. What time this line lasted we do not know. Probably it did not exceed a generation. Horus occupied himself in destroying the monuments of Khn-n-aten and his successors, and no doubt in fully restoring the national religion.

Another family gained the throne after the reign of Horus, that of the Ramessides, forming Dynasties XIX. and XX.¹ Ramses I., who seems to have been of Lower Egyptian extraction, and not impossibly connected by ancestry with the Shepherd kings, seized the royal power, maintained his authority abroad by campaigns in the south and the east, and concluded a treaty of peace with the king of the Hittites. After a very short reign he left the crown to his son Setee I., or Sethos, who strengthened his rights by marrying Tai, a granddaughter of Amenophis III. Ramses II., the son of this marriage, thus became legitimate king, and Setee made him his colleague at a very early age, no doubt to conciliate the Egyptians, a position at first ignored, evidently owing to the difficulty of defining it, but which ended in the virtual abdication of Setee (Maspero, *Hist. Anc.*, 215-217). The troubles that preceded the reign of Ramses I. must have weakened the foreign dominion of Egypt. Wars in the east occupied the earliest years of Setee. The Kheta had now succeeded to the Ruten in the supremacy of Northern Syria. Although Setee conquered the Kheta and captured Kadesh, now their chief town, the war ended by the conclusion of a second treaty between the Egyptian and Hittite kings. It is not necessary to suppose, with M. Maspero (*Hist. Anc.*, 215), that the Egyptian Empire was already waning, because it was thus barred off from Further Asia and obliged to meet the Hittite king on

¹ The chronology of Dynasty XIX. presents one great difficulty. We cannot determine the length of the reign of Setee I. Manetho assigns him more than 50 years, which is most improbable, as Ramses reigned 67 years, and his father and mother were married before his father's succession. Ramses dates from his accession as sole king, and therefore we cannot include a period of co-regency in the Manethonian numbers for Sethos. The size and beauty of Setee's tomb would imply a reign of not under 30 years. The length of the Dynasty cannot have been less than 120 years, and was perhaps as much as 150. It comprised three generations and the rest of the probably long life of the king (Setee II.) whose birth marked the third, which would give 100-40 (?) about 140 years for the total duration.

equal terms. The conditions were no doubt changed from those of the time of Thothmes III., but the list of the confederacy which the next king of the Kheta led against Ramses II., compared with that which Thothmes defeated at Megiddo, shows that the Kheta could bring into the field much more formidable allies than did the Hittites. Moreover there was a change in the foreign policy of Egypt. Phœnicia and Palestine were ruled by means of a chain of fortresses held by Egyptian garrisons. (Brugsch, *Hist.*, 1 ed. 135; Maspero, *Hist. Anc.*, 215.) If the Empire was narrowed in its limits, it was more solidly ruled; and this is quite consistent with the conclusion of a treaty with the Kheta. As a bulwer Setee I. is only equalled by Ramses II. He constructed the great hall of columns of El-Karnak, on the outside of the north wall of which he commemorated his victories in a series of most interesting sculptures. His splendid tomb is in the Valley of the Tombs of the Kings.

Ramses II. is without doubt the greatest figure in the long line of the Pharaohs, and at the same time he is the one of whose character we have the best idea. His early training was in war and in government, for it cannot be a pure figure of speech by which the tablet found near Dakkeh in Nubia says that when he was but ten years old no monuments were executed without his orders (Brugsch, *Hist.*, 1 ed. 137). This position was due to his superior right to the throne. Before the death of Setee I. the maritime nations of the Mediterranean made a descent on Egypt. The Shardana, or Sardones, and the Tuirsha, or Tyrseni, allied with the Libyans in this enterprise. Ramses defeated them so effectually that they do not seem to have again attacked Egypt till the reign of his son Menptah, about seventy years or more later. The captives of the Shardana instead of being employed in public works were enrolled in the king's guard. After an expedition against Ethiopia, Ramses, on the death of Setee, returned to Egypt. Early in his sole reign the peace between the Egyptians and the Hittites was broken. The king of the Hittites formed a great confederacy. The nations of Asia Minor, the Mysians, the Lycians, the Dardans, the people of Ilium, are found in the list of the poem of Pentaur, the Egyptian Ramessesid, which appropriately records the oldest war in which Troy had a part. To bring together the army of the confederates time must have been needed. Probably the war was determined on by the Hittites on the accession of the new king. The great campaign was that of the fifth year of Ramses. The decisive battle was preceded by a repulse, when the Egyptian army, deceived by the Arabs (Shasu), were suddenly, while on the march, attacked and routed by the enemy, who numbered no less than 2500 war-chariots. It was only by the personal bravery of Ramses that the Egyptians escaped destruction. This incident is the main subject of the poem of Pentaur. But on the next day the great battle was fought; the confederates were beaten and retreated into Kadesh. The Hittite king now sued for peace, which was granted. It was speedily broken. In his eighth year Ramses took Shalam, probably Salem or Jerusalem, Maram (Merom), and Tapur (Dabir? near Mount Tabor), Bethanath, and Kamon. In his eleventh year he captured Ascalon. The war does not seem to have been ended until the Hittite king Khetasar proposed conditions of peace which he brought to Ramses written on a silver tablet. The treaty concluded on these bases in the twenty-first year of Ramses is sculptured at El-Karnak. It is a most interesting document, being an alliance offensive and defensive, with articles of extradition, remarkable for their humanity, and others for the protection of commerce (Maspero, *Hist. Anc.*, 222, 223). Both kings swore to observe the compact, which was a renewal of the previous treaties. It is remarkable that in this document the Hittite

prince, instead of being called the "vile chief of the Kheta," is now the "great king," the style given to Ramses also. The eldest daughter of the Hittite king was taken in marriage as queen by Ramses, in whose twenty-third year Khetasar visited his son-in-law in Egypt. This alliance does not seem to have been broken for full a century, and then by conquerors who overcame the resistance of the Kheta and carried them with them. The remainder of the reign of Ramses appears to have been undisturbed by great wars, and given up to those vast buildings which are found throughout Egypt and Nubia, and which give him the first place among the architect Pharaohs. About the thirtieth year of his reign, his fourth son, the eldest surviving, was made regent, and on the death of this prince in the fifty-fifth year, Menptah the thirteenth son, now heir, took this post, holding it for the rest of his father's reign, which ended in the sixty-seventh year. Ramses must then have been at least near a hundred years old, perhaps more.¹ He married three queens, and apparently had by them 23 sons and at least 13 daughters. The whole number of his children was 170, of whom 111 were sons and 59 daughters. All are styled princes or princesses, but probably only the children of queens had the right of succession.

Menptah succeeded Ramses II. There are but few monuments of his reign. The principal event they relate is a great incursion into the Delta of the maritime nations of the Mediterranean allied with the Libyans. By this time the Pelasgic tribes had wrested the dominion of the sea from the Phœnicians. Some causes, perhaps famines, had already disposed them to move from Asia Minor and the Greek islands, seeking new establishments in Egypt. The attempt that Ramses II. defeated in the lifetime of Setee I. was now renewed, apparently on a more formidable scale. The king of the Rebu (Libyans), with the warriors of several tribes joined the Shardana (Sardones), the Shakalasha (Sikels), the Leku (Lycians), the Tuirsha (Tyrseni), and the Akaiusha (Achæans). They had already entered Egypt and spread themselves over the west of the Delta, where they intended to settle, when the Egyptian forces attacked them and put them to rout after a battle of six hours' duration. It is remarkable that in this confederacy the Shakalasha and Akaiusha are added to the former list, and the Leku, who were in the Hittite confederacy against Ramses II., now appear on the west. Everything indicates the growing strength of the maritime nations and that power of united action which marked the period of the Trojan War. For the time the invasion was checked, but the Empire was evidently failing. The Hittites, indeed, were true to the treaty, and during famine were supplied with corn from Egypt, and the external provinces seem to have continued quiet. But side by side with the kingly power that of the high priests of Amen-ra had grown to formidable dimensions, owing probably to the interest Ramses II. and Menptah showed for Lower Egypt, which put the weight of Thebes on the side of the highest local functionary. Menptah was not immediately followed by his son Setee II. There intervened two reigns, those of Amenemeses and Siptah, the first of the Ramses family by descent, the second, apparently, by marriage. They appear to have

¹M. Maspero thinks Ramses II. was at least 50 in the 21st year of his reign (*Hist. Anc.*, 250). This would make him at least 98 at the time of his death, and 30 at his accession. The latter age is barely reconcilable with the fact of three of his sons of the restricted class, which is evidently composed of the children of successive queens, being engaged in the campaign of the 5th year. Putting his marriage at 16, we must allow at least 4 years for the birth of these three sons, and cannot suppose the youngest to have gone to war in his chariot under the age of 14. If so (16 + 4 + 14 =) 34 is the lowest age for the fifth year, and 29 for the accession, or 49 for the 21st year. But it is obvious that probability is against these extreme limits, and the fact that Ramses outlived twelve of his sons of the shorter list is in favour of a greater age.

been of a branch holding a local principality. Setee II. succeeded them and restored the legitimate line. His reign closed in anarchy. There was no longer one king: the chiefs of the nomes ruled and engaged in civil war. A worse period followed. A Syrian, Arisu by name, became chief of the nomarchs, society was dissolved, and the temple-services neglected. We are as yet unable to say how this revolution began. It seems to have had nothing to do with foreign wars, but to have been brought about by internal weakness. The time it lasted must have been long, according to the Papyrus of Ramses III., from which alone we know of it. There "many years" are assigned to the period of the nomarchs and "years" to the rule of the Syrian.

As the Exodus is now generally held to have occurred in the later years of Dynasty XIX., its place in Egyptian history may best be here noticed. The view referred to was first carefully worked out by Prof. Lepsius. It rests upon chronological and historical grounds. Manetho, apparently adopting a tradition, placed the Exodus in the reign of Menptah. The number of generations assigned in the Bible to the interval from the Exodus to Solomon would bring the former event to about the same time. This approximative date is in accordance with that of the Rabbinical chronology, B.C. 1314-13. The coincidence is, however, valueless, for the interval from the Exodus to the building of Solomon's Temple, in the Rabbinical chronology, is that of the Hebrew text, 480 years. The date of the Exodus should therefore be about B.C. 1480. The difference between 1480 and 1314-13 is caused by an error in the date of the building of the Second Temple, which is put B.C. 354, only 46 years before the date of Alexander's death, which is dated B.C. 308, or 15 years too late. There is thus a mistake of more than a century in so cardinal a date as the building of the Second Temple. If an event of this importance, occurring only 800 years before the drawing up of the chronology, is thus incorrectly dated, and a period of Jewish history obliterated, surely the date of the Exodus cannot rest upon any accurate information. The historical grounds are far stronger than the chronological. Manetho, relating, if we may trust Josephus, a current tradition (*ὑπὲρ ὧν δ' ὁ Μανέθων οὐκ ἐκ τῶν παρ' Αἰγυπτίους γραμμάτων, ἀλλ', ὡς αὐτὸς ὁμολογῇ, ἐκ τῶν ἀδεσπότης μυθολογουμένων προστίθει, ὑπερὸν ἐξελέγξω κατὰ μέρος, κ. τ. λ.*, *Contr. Ap.*, 16), and Josephus is here confirmed by the evidence which the narrative shows of historical inaccuracy, has given an account of the Exodus from an Egyptian point of view. This story is the fullest version of one current in various forms in antiquity. As Manetho tells it, the chief points are these. King Amenophis, identified by him with Menptah, who occurs in his lists as Amenophis and Ammenephthis, determined, under the advice of a priest of the same name as himself, Amenophis the son of Papis, to cleanse Egypt of all lepers and other unclean persons, whom, accordingly, he set to work in the quarries. On their petition he gave them the city Avaris, left in ruins by the Shepherds. Having occupied the city, they chose one of themselves, a priest of Helopolis, by name Osarsiph, as their ruler, who changed his name to Moyses. He made laws particularly directed against the Egyptian religion, and sent messengers to Jerusalem to the Shepherds, who had been expelled by the Egyptians, asking their aid and promising to give them their old territory Avaris, and to assist them to subdue Egypt. Accordingly the Shepherds invaded Egypt, when Amenophis came against them, but for superstitious reasons did not fight them, and withdrew to the friendly king of Ethiopia, in whose country he remained thirteen years, his ally protecting the southern Egyptian border. Meanwhile the people of Jerusalem and the unclean Egyptians ravaged Egypt, and destroyed everything connected with the national religion. Afterwards Amenophis

and his son Sethos, also called Ramesses, returned and expelled the Shepherds and the unclean people. Chæremon gives a similar account with the same name for the king. Lysimachus and Tacitus vary in calling the king Bocchoris.

The Egyptian evidence for the date of the Exodus would place it about this time. The geographical inquiries of Lepsius have been carried on by Brugsch, who, in a paper read before the Oriental Congress, has identified the principal geographical names of the narrative of the oppression and of the Exodus (Brugsch, *L'Exode*). In particular, Rameses is shown to have been another name of Tanis. The occurrence of this name in Genesis and Exodus is most important as bearing on the date of the Exodus, for it is almost certain that it was given by Ramses II., who rebuilt the great temple of the town. Another cardinal piece of evidence is the mention of the 'Aperu, or 'Apuriu, as engaged in public works under Ramses II. and later kings, but not after Dynasty XX. In this name that of the Hebrews has been recognized. If the identification were certain we should have much reason for dating the oppression under Ramses II., which would accord with the Exodus under Menptah.

The difficulties of this theory are not slight. On the chronological side Manetho's date is only dependent on a tradition, and we cannot fix the chronology of the dynasty, B.C. 1300 for Menptah being about the middle point in a doubtful two centuries. The evidence of the Hebrew genealogies therefore is not conclusive for a date identical with that of Menptah, which we cannot yet say is irreconcilable with the chronology founded on the interval of 480 years from the Exodus to the building of Solomon's Temple. If, however, the genealogies are to be taken as a guide for the chronology up to the Exodus, Egyptologists prefer for the period of the sojourn the longer intervals stated in the Hebrew text to the very short ones that would result from the genealogical method. Still greater difficulties arise when we give a critical examination to Manetho's story. It reads like a perverted narrative of the calamities which closed Dynasty XIX., for we cannot suppose two conquests by Asiatics and two expulsions, one by Menptah and Setee II., the other by Set-nekht, who subdued the Syrian, nor resort to the violent hypothesis that the Papyrus of Ramses III. attributes to Set-nekht that which Setee II. achieved. The name of Amenophis is suspicious, the two names of his son Sethos, "who is Ramesses," still more so; the recall of the Shepherds from Jerusalem, and the easy conquest of Egypt without a battle, all read like a legend founded on a fusion of the two periods of Eastern occupation. There is, moreover, another suspicious circumstance in the occurrence of the name of Bocchoris in two versions of the story. This would either point to Bocchoris of Dynasty XXIV., in whose time it is quite possible that there was a large number of Israelite fugitives in Egypt, or to some other king of the same or a similar name; we do not, however, know of any earlier Bocchoris. It may be reasonably asked whether this story has anything to do with the Exodus. Those who hold that it has yet, in common with all Egyptologists, argue, when they examine the Biblical data, on the ground of the minute accuracy of many of these data. If, then, the two narratives, that of Manetho and that of the Papyrus of Ramses III., relate to the Exodus, it may reasonably be inferred that the Manethonian is a faulty and distorted one. It is, however, quite possible that Manetho may have known when the Exodus happened, and yet may have confused it with an event of the same period. The argument from the Biblical data that Ramses II. ruled during the oppression of the Israelites is very strong, though it may be conjectured that a redactor has substituted the later name Ramesses for the earlier Zoan.

The name of the 'Aperu, if certainly that of the Hebrews, would be decisive, but it is not a proper Egyptian equivalent, and so exact are the transcriptions of Semitic geographical names into Egyptian, that upon them mainly depends the theory of the sounds of the Egyptian alphabet developed by M. de Rougé and adopted by Dr Brugsch. Here, again, the evidence is inconclusive.

The arguments which would place the Exodus in any other period of Egyptian history are but slight. There is indeed the remarkable occurrence of a name similar to that of Jacob, or identical with it, in a record of the conquests of Thothmes III.¹ This may only be a reminiscence of Jacob, as M. de Rougé suggests, but it would be more natural to take it to indicate that the Exodus was anterior to the time of Thothmes, and there are other names in the list which may possibly point to the same conclusion.¹ Yet the preponderance of evidence is at present greatly in favour of the occurrence of the Exodus towards the close of Dynasty XIX. It is not, however, necessary to accept the date of Prof. Lepsius, in our present state of uncertainty as to the chronology of Dynasty XIX. It is also not a necessary consequence of accepting this historical synchronism, that we should take Manetho's narrative of the Exodus as more than his identification with it of an event of the same period. These may seem but unsatisfactory results of the great erudition which has been bestowed on this question. We refrain from speaking more positively when a discovery may at any moment render speculation needless.

If the Exodus took place towards the close of Dynasty XIX., when did the period of oppression and the government of Joseph fall? The reckoning by generations would place Joseph in the later part of Dynasty XVIII., and the oppression under Ramses II. downwards. It is, however, very generally acknowledged that this method of computation is not consistent with the growth of the Israelites from a family to a nation during the sojourn in Egypt. Scholars are therefore disposed to choose a reckoning by years. Here the Biblical data give either 430 years exactly for the sojourn and 400 for the oppression, or else 215 years for the sojourn. The longer periods are those generally preferred. If we reckon by them, the government of Joseph would have fallen under the last Shepherd king, and the oppression would have probably begun under Aahmes, to be greatly increased in intensity under Ramses II.

Set-nekht, a chief probably of the line of Ramses II., overthrew the Syrian intruder and again restored the Egyptian monarchy. His short reign, which begins Dynasty XX.,² was probably entirely occupied in reorganizing the administration of Egypt. Ramses III., whom his father had already made his colleague (Maspero, *Hist. Anc.*, 262), succeeded to a united Egypt but a distracted Empire. Evidently in the time of anarchy every province and tributary state had fallen away. The new king was equal to the effort of repelling invasion at home and reconquering lost territory abroad. In his fifth year he defeated the Libyan tribes who had invaded the west of Lower Egypt.

¹ In this list Iâkah-nar is read by M. de Rougé as representing Jacob-el, a form like Nathaniel for Nathan (*Rev. Arch.*, n.s. iv, 370).

² The chronology of Dynasties XX. and XXI. is extremely obscure. We know that Ramses III. reigned 32 years, and Ramses XI. or XII. upwards of 32 years. The six successors of Ramses III. probably had very short reigns, as all but the second and sixth were certainly sons of that king, and the sixth probably. The other kings are represented by few monuments. Hor-har, however, may have had a longer reign, the sculptures of the temple of Khons at Thebes giving this impression. There does not seem, however, to be any ground for a duration of more than a century until the Tanites of Dynasty XXI. rose into power. The latest Theban kings probably held a local and constantly diminishing authority for part of the time of the Tanites, of whom the records are extremely scanty and the chronology consequently obscure. Two centuries is a probable measure of the whole interval.

In his eighth, he met another attack from the opposite quarter. The Taanau (Danai?) and the Takkaru (Teucrians), who now first appear, forming with the Tuirsha (Tyrseni), Washasha (Oscans?), Shakalasha (Sikels), Leka (Lycians), and Pelesta (Philistines), a great confederation, which attacked the east of Egypt by sea and land. Their army conquered and carried with it the Kheta and neighbouring tribes. Their fleet, manned by the Takkaru and Shardana, reached Egypt at the same time. The Egyptian army and fleet encountered and defeated them. This campaign, and particularly the sea-fight, form the subjects of interesting reliefs in the great sepulchral temple built by Ramses III. in western Thebes. In his eleventh year a second invasion of the west of Egypt, by the Libyans, aided by the Tuirsha and the Leka, was equally unsuccessful. The eastern provinces and tributary states were recovered, and an expedition was sent to the Somâlec country on the eastern coast of Africa or Arabia Felix. This last great conqueror finally preserved Egypt from the maritime nations. The course of their migrations seems to have been changed. All that remained of their invasions were the Philistine settlement in Palestine and one of the Mashuasha, a Libyan tribe, in the Delta, from whose race the Egyptians drew mercenaries (Maspero, *Hist. Anc.*, 266). The importance of these forces is evident in the Biblical notices of Egypt of the time of the Hebrew kings.

The historical value of the Egyptian notices of the primitive populations of the Mediterranean is being more and more perceived. It is at first perplexing that we find the nations afterwards settled in well-known seats either far to the east or in constant movement. Yet the key thus afforded to the earliest Greek colonization is most valuable, and it is significant of the historical character of the documents that new names appear, as we should expect, in such a manner as to explain the confusion of the Greek terms, which speak of Achæans and Danai, Dardans and Teucra, at the same time indifferently, whereas the Egyptian documents show that they are not interchangeable. Ramses III., besides constructing the magnificent temple at Medinet Haboo, enriched the temples of Egypt with splendid gifts, during a prosperous reign of thirty-two years. The later kings of the dynasty do not appear to have achieved anything remarkable. They maintained the Empire, but their authority at home waned, while that of the high-priests of Amen grew until, towards the close of the dynasty, Her-har, one of these high-priests, gained the royal power. Probably the close of the dynasty was occupied by a struggle between the last Ramesside kings and the high-priests, as well as by the additional distraction caused by the rise of another line, Dynasty XXI., of Tanite kings. Probably the Tanites ultimately gained the sole authority. The high-priests of Amen-ra, about this time, certainly not later than the rise of Dynasty XXII., retreated to Ethiopia, where they founded a kingdom, of which the capital was Napata. The Pharaoh whose daughter Solomon married was, if Manetho's numbers are correct, Psusennes II., Har-Psiuukha, last king of Dynasty XXI. He seems to have endeavoured to restore the military power of Egypt, for he made an expedition into Canaan and captured the town of Gezer, which he gave to his daughter, Solomon's queen.

During the later period of the Empire, partly through marriages of the Pharaohs, partly in consequence of the large employment of mercenaries, chiefly Libyans, great settlements of foreigners, Asiatic as well as African, were established in Egypt. So far from the Shemites being then disliked, a multitude of Semitic words were introduced into Egyptian, and it even became the fashion to give a Semitic form to native words (Maspero, *Hist. Anc.*, 337, 338). A Shemite family, settled at Bubastis, or in the Bubastine

nome, succeeded by the command of mercenaries and by alliances with the Tanite family in establishing a new royal line, Dynasty XXII, which is remarkable for its foreign names. The royal names Sheshonk, Osorkon, Takolot are all either Assyrian or Babylonian. Still more striking is the name Nemrut, or Nimrod, borne by non-kingly members of the family. Probably it came from the further East.

Sheshonk I., the Shishak of the Bible, may have gained the royal power peaceably. His son Osorkon married the daughter of the last king of the Tanite Dynasty, to whom Sheshonk succeeded. He seems early to have entertained the design of restoring the Egyptian rule in the East, for he received Jeroboam when he fled from Solomon. The revolt of the Ten Tribes enabled him to carry out this project, and late in his reign he marched against Rehoboam, and returned with the treasures of the Temple and the palace. A remarkable sculpture at the temple of El-Karnak gives a list of 130 names of towns and peoples conquered by Shishak in this expedition. Long as is the list, it is not like the rolls of the conquerors of the Empire. The items are far less important, and the Hagarites recur several times, as if to record the subjugation of a series of small Bedawee tribes. Cities of Judah and Israel appear in the list, but the towns in the kingdom of Jeroboam seem to be Levite and Canaanite, and it is probable that the Israelite king was not averse to their overthrow. With this occurrence we gain the first good chronological footing in Egyptian history. The Hebrew chronology is indeed not as yet fixed. The Assyrian monuments seem to indicate a reduction of at least twenty-three years in the ordinary dates. The invasion of Shishak is ordinarily dated B.C. 971, but may thus have to be lowered to about B.C. 948; and as it probably took place in about the twentieth year of the Egyptian king's reign, his accession may be dated approximately B.C. 967.

The government of Egypt under the kings of Dynasty XXII, underwent an important change. They made the high-priesthood of Amen-ran an office of a prince of the family, usually the eldest son, and gave high governments to other princes. Thus the power of the Pharaoh ultimately became merely nominal, and Egypt resolved itself into an aggregate of principalities. A further cause of decay was the importance of the Libyan mercenaries which each of the princes commanded. Under a new dynasty, XXIII, said to be of Tanites, but probably kindred to the Bubastites, Egypt was, for a time at least, reunited under a single rule, but towards its close the process of disintegration had already again set in, and the country was divided among nearly twenty princes, at least four of whom took the royal insignia (Maspero, *Hist. Anc.*, 378 seqq.).

Among these small princes but one was capable of attempting to reunite Egypt under his rule. This was Tafnekht, Tnephachthos, prince of Sais, who reduced great part of the country, and would probably have achieved complete success, had not the yet unconquered princes called in the priest-king of Napata, Piankhi Meriamen. While Egypt had declined, Ethiopia had constantly risen, and at this time part of the Thebais owed it allegiance. Piankhi, the descendant of the priest-kings of Thebes, was not unwilling to recover his ancient dominions. In one brilliant campaign he defeated Tafnekht and his allies, captured their strongholds, and obtained the sovereignty of Egypt, leaving the small princes to rule as his vassals. The ancient Empire was thus in part restored, but as it was ruled from Ethiopia, and the little princes constantly strove for independence, it had no real durability. Piankhi was succeeded by Kashta, who was probably an Ethiopian, owing his throne to his intermarriage with a princess of the Theban line.

Bokenranf, or Bocchoris, son and successor of Tafnekht, no doubt seizing this occasion, was able to carry out the pro-

ject of his father and make himself king of Egypt. After a short reign marked by energy and prudence he perished in a fresh Ethiopian invasion. Shabak, or Sabakon, conquered Egypt, and having taken Bokenranf in his capital, Sais, put him to a cruel death. It was no longer an Egyptian prince who ruled at Napata; all the circumstances we know of Shabak and his dynasty indicate an Ethiopian line, governing Egypt as a conquered country, not as their ancient territory. Still Shabak's connection with the priestly line was not forgotten. His sister, Queen Ameniritis, governed Thebes, and the power of the local rulers was limited, not destroyed. Hoshen, king of Israel, sent presents to Shabak,¹ who was subsequently drawn into a confederacy of Syrian and other princes against Sargon king of Assyria, but, as in all these wars, the Ethiopian king was a tardy ally. His capital lay too far south, and in crossing the eastern border of Egypt he left the ill-affected princes of the Delta in the lino of his communications. He therefore came into the field too late, and it was but little east of Egypt that he met the Assyrians and experienced a disastrous defeat at Raphia. He lost great part of Egypt, in which the small princes again established themselves, now as vassals of Assyria, Shabak only retaining Ethiopia and part of Upper Egypt.

Shabatok, or Sebichus, was the son and successor of Shabak. He made himself supreme king in Egypt, but appears to have lost Ethiopia to Tahraka. Towards the close of his reign the Egyptian dynasty joined in an alliance against Sennacherib, who had recently succeeded Sargon. The confederates were defeated, or made their submission one by one. The Egyptian princes lost a battle in southern Palestine, in the territory of their ally Merckiah, who was the last in the East to submit. But the Egyptians again advanced, encouraged by Tahraka, king of Ethiopia, who marched to their support. No battle was fought. The Assyrians moved against the Egyptians, but in one night the invading army perished, and Sennacherib fled to Nineveh. The tradition of the Egyptians agrees with Biblical history in relating the destruction of the Assyrians as miraculous; and it should be noted that for the rest of his reign Sennacherib never ventured again to invade Palestine. During this interval of respite Tahraka entered Egypt, slew Shabatok, and made himself master of the whole country (B.C. 692).

After twenty years of what seems to have been a peaceful reign, the Assyrian war began afresh, Esarhaddon, son and successor of Sennacherib, resolving on the subjugation of Egypt. Tahraka was vanquished and fled to Napata, and Memphis and Thebes were taken. The country was divided between twenty princes, with Neku I. of Sais as their chief. The fortresses were garrisoned with Assyrian troops (B.C. 672). In a few years, however, Tahraka returned, defeated the Assyrians, and captured Memphis. In commemoration of the earlier subjugation or of this one, the Ethiopian king puts the name of Egypt among those of conquered nations not only at Napata but also at Thebes (Maspero, *Hist. Anc.*, 427; Brugsch, *Hist.*, 1 ed., 244, 245). Soon after Esarhaddon abdicated in favour of his son Asshur-bani-pal, who speedily invaded and reconquered Egypt, driving out Tahraka and restoring the tributary princes. As soon, however, as he had left, a conspiracy broke out, and these chiefs sent emissaries to Tahraka. They were overcome by the Assyrians, and Neku and two others sent in chains to Nineveh, before Tahraka could come to their aid. But he again reconquered Thebes and Memphis. Asshur-bani-pal now made a politic use of the Egyptian party, treated Neku with honour, and sent him back to Egypt as ruler of Sais, giving a second principality to his son Psametik. Neku returned to find that Tahraka

¹ With this transaction Shabak's record at El-Karnak of the tributes of Syria has been connected (Maspero, *Hist. Anc.*, 380).

had left Egypt (B.C. 666). Urdamen, Tahraka's son-in-law and successor, held Upper Egypt, and at once attacked the Assyrians, captured Memphis from them, and took Neku, whom he put to death, while Psametik fled into Syria. Asshur-bani-pal now invaded Egypt, defeated Urdamen, and sacked Thebes, carrying the whole population captive. The twenty principalities were again set up, but Psametik was not the chief.

After a time the Egyptian princes became independent of Assyria, but they had once more to submit to an Ethiopian invader, Nout-Menamen, who reconquered the country without much difficulty, but does not seem to have long held it. The Saite prince Psametik, whose ambition excited the jealousy of the other dynasts, at last achieved the object for which his predecessors had pertinaciously fought. By the aid of Carian and Ionian mercenaries he put down his rivals, and by a marriage with the niece of Shabak rendered his line legitimate. This alliance with a princess only a generation younger than the first Ethiopian king brings into striking relief the vicissitudes which Egypt underwent during the Assyrian wars. Calamities were crowded into those years which usually occupy centuries. Yet under the new king, who was the real founder of Dynasty XXVI., Egypt rapidly recovered, and during the rule of his successors it was for the first time since the Empire strong and united, enjoying a true national existence. Public works of all kinds were carried on with energy. Art, which had fallen under the Bubastites and their followers, now suddenly revived, and with its recovery the ideas of the primitive dynasties came into fashion. The style of the age may be best compared with that of Dynasties IV. and V. It is, however, wanting in vigour, using elongated forms and abundant details. Still it has an elegance and a mastery of material which show that Egypt had not lost the true feeling of its art, in spite of the disastrous wars which had threatened the overthrow of all the institutions of the country.

Psametik I., or Psammetichus, employed his long reign in strengthening Egypt and in restoring the temples and making additional monuments. He recovered from Ethiopia a part of Lower Nubia, and made a successful expedition into Philistia. His designs of conquest were, however, frustrated by a wholesale desertion of Egyptian troops, caused by jealousy of the Ionian and Carian mercenaries to whom Psametik owed his throne. The mutineers, whose number Herodotus puts at 240,000 men, were too strong to be resisted, and deaf to the king's intreaties marched to Ethiopia and received lands from the king of that country. All that the Egyptian sovereign could do was to form a new army and build a fleet. He thus missed the opportunity afforded by the decline of Nineveh of winning back the influence Egypt had long lost in the East. An interesting memorial of his reign is the Greek inscription on one of the colossi of Aboosimbel, in Nubia, recording the visit of mercenary and Egyptian troops.

Neku II., B.C. 611, son and successor of Psametik, inherited his father's energy but not his prudence. He attempted to complete an enterprise of the Empire and connect the Red Sea with the Nile, and so with the Mediterranean, by a canal. Under his orders Phœnician seamen circumnavigated Africa. Less fortunate was his attempt to recover the eastern rule of Egypt. He marched against Megiddo, still the key to the route to the Euphrates. Here he was met by the forces of Josiah, king of Judah, with whom he unwillingly fought. Josiah was slain, and the king of Egypt advanced to Carchemish on the Euphrates. Thus the Egyptian Empire was for a moment restored. There was no great eastern rival to contest its supremacy. Assyria had fallen, Babylon was not yet firmly established. After about three years Nabopolassar, the king of Babylon,

sent his son Nebuchadnezzar against the Egyptians. At Carchemish the armies met. Neku was defeated, and the Egyptian rule in the East finally destroyed. Soon after the king of Egypt died, leaving his throne to his son Psametik II., B.C. 595, whose short reign was only marked by an expedition against the king of Ethiopia. The next king, Psametik's son, Uahabra, or Apries, the Pharaoh Hophra of Scripture, B.C. 590, inherited the energy and ambition of the Saite house. His accession was the signal for a general confederation of Palestine and Phœnicia against the king of Babylon. The war was speedily ended by the capture of Jerusalem, which Uahabra in vain endeavoured to prevent. He was, however, successful at sea. His Greek ships beat the Phœnician fleet of Nebuchadnezzar, and for a time he held the Phœnician coast, and aided Tyre in a resistance of thirteen years against the Babylonian besiegers. A great disaster lost Uahabra his throne. He engaged in a war with the Greeks of Cyrene. His Egyptian troops were defeated. The native soldiers believed that he had planned their destruction that he might put mercenaries in their place. They revolted and chose Aahmes, or Amasis, king. Amasis defeated the mercenary troops of Uahabra and dethroned him, B.C. 571. It is to this time that the conquest of Egypt by Nebuchadnezzar is assigned by Josephus. The silence of Herodotus and the other Greek historians, and the prosperity of Egypt under Amasis, have induced modern scholars to suppose that Josephus based his statement on the prophecies of Jeremiah and Ezekiel. If, however, we read between the lines of the story of Herodotus, we need some other cause than the disaffection of the Egyptian troops to account for the sudden success of Amasis, and especially for his easy defeat of the mercenaries with a discouraged native force. Again, the conquests of Egypt by the Assyrians, though predicted by Isaiah and noticed as past by Nahum, are unrecorded by Herodotus and the Greeks. The prosperity of the country in the reign of Amasis might as easily follow a Babylonian conquest as that under Psametik I. followed the terrible Assyrian wars. The scantiness of the native records of Nebuchadnezzar's reign leaves us without Babylonian evidence.

Amasis took to wife a grand-daughter of Psametik I. and his heiress-queen Shapentap, thus legitimatizing his pretensions. He greatly embellished the temples of Egypt. It may be that, as in the time of Psametik I., they needed restoration. His foreign policy was marked by energy and caution. He transferred the Ionian and Carian mercenaries to Memphis itself as a force of guards. He granted the Greeks the free use of Nauaratis as a Hellenic settlement and trading port. He conquered Cyprus, and kept up the influence of Egypt in Phœnicia. He had friendly relations with the Greek states, and instead of conducting an expedition against the Babylonians during their Empire or against the rapidly rising power of the Persians, he joined in an alliance of which Crœsus, king of Lydia, was the head, and agreed to furnish him with an Egyptian contingent in his war with Cyrus. After the fall of Crœsus other wars kept Cyrus from any designs on Egypt, and it was not until the accession of his son Cambyes that the Persians could attempt its reduction. Meanwhile Amasis died, leaving the crown to his son Psametik III., the Psammenitus of Herodotus, who, after a single well-fought battle near Pelusium, and the capture of Pelusium and Memphis, lost his kingdom, B.C. 525.

Cambyes, as we learn from the narrative of the Egyptian priest Uta-lar-sun of Sais, at first adopted the style of a Pharaoh, and was initiated into the mysteries of Neith at Sais. It was not until the failure of an expedition against the Oasis of Ammon, and of another directed by himself against the Ethiopian kingdom of Napata, that Cambyes, probably aware of the satisfaction the Egyptians must have

felt at these reverses, changed his policy, and vented his rage upon the monuments and objects of worship in Egypt. The Saite priest, in general terms, describes this as a time of calamity such as had never before befallen his country. Cambyzes left Egypt, which was so completely crushed that the subsequent usurpation of the Magian was marked by no revolt. One of the first cares of Darius I. was to charge Uthar-sun with the restoration of the disordered country. In a visit to Egypt at the moment when a revolt had broken out, he pacified the people by supporting their religion, in the most marked contrast to Cambyzes. For the rest of his reign he endeavoured to promote the commercial welfare of Egypt, in particular opening the canal from the Nile to the Red Sea. In the Great Oasis he built a temple to Ammon. It was not until the very close of his reign that the Egyptians rose against his rule, and expelled the Persians, choosing as king Khabbash, whose name has been discovered in the Sarapeum. The revolt lasted but three years, and Xerxes I. suppressed it with severity. Achæmenes, the brother of Xerxes, was made satrap. Egypt did not again rise until the troubles which marked the accession of Artaxerxes I. The insurrection was led by Inaros, prince of Marea, who immediately concluded an alliance with the Athenians. Supported by 200 Athenian triremes, he defeated and slew the satrap Achæmenes, and besieged in the citadel of Memphis the remnant of the Persian army, which, though it included Egyptian soldiers, held out until the attacking force was drawn off by a fresh Persian army. The Egyptians and their allies were now driven to the island of Prosopitis, and there besieged for eighteen months. At last Inaros was taken and put to death, Amyrtæus, an Egyptian who reigned with him, fled to the marshes, where he long maintained himself. Artaxerxes, after this serious revolt of six years, modified the administration of Egypt, recognizing Thanuyras, son of Inaros, and Pausiris, of Amyrtæus, as vassal kings. The government was, however, held by a Persian satrap; these were merely local princes.

An Amyrtæus, probably son of Pausiris (Maspero, *Hist. Anc.*, 562), revolted, and on the death of Darius II., B.C. 404, made Egypt virtually independent. He is the one king of Dynasty XXVIII., Saite. His successor, Naïfaaurut I., founded Dynasty XXIX. of Mendesians, B.C. 399. With him the monuments, silent since the rising of Khabbash, again give us information, and under the next dynasty show that the Saite art still lived in spite of the misfortunes the country had undergone. The Mendesians Naïfaaurut and Hakor are chiefly known for the part they took in aiding the enemies of Persia. Hakor was followed by Naïfaaurut II., and then the sovereignty passed to Dynasty XXX. of Mendesians, the last native Egyptian line. The first of these kings, Nekht-har-heb, or Nectanebes I., came to the throne when a Persian invasion was imminent, B.C. 378. Hakor had already formed a powerful army, largely composed of Greek mercenaries. This army Nekht-har-heb intrusted to the Athenian Chabrias. The Persians, however, succeeded in causing his recall and in gaining the services of his fellow-countryman Iphicrates. The invading army consisted of 200,000 barbarians under Pharnabazus and 20,000 Greeks under Iphicrates. After the Egyptians had experienced a reverse, Iphicrates counselled an immediate advance on Memphis. His advice was not followed by Pharnabazus, the Egyptian king collected his forces and won a pitched battle near Mendes. Pharnabazus retreated, and Egypt was free.

Nekht-har-heb was succeeded by Tachos or Teos, whose short reign was occupied by a war with Persia, in which the king of Egypt secured the services of a body of Greek mercenaries under the Spartan king Agesilaus and a fleet under the Athenian general Chabrias. He entered

Phœnicia with every prospect of success but having offended Agesilaus, he was dethroned in a military revolt which gave the crown to Nekht-nebf, or Nectanebes II., the last native king of Egypt. At this moment a revolt broke out. The prince of Mendes almost succeeded in overthrowing the new king. Agesilaus defeated the rival pretender, and left Nekht-nebf established on the throne. But the opportunity of a decisive blow against Persia was lost. The new king, Artaxerxes III. Ochus, determined to reduce Egypt. A first expedition was defeated by the Greek mercenaries of Nekht-nebf, but a second, commanded by Ochus himself, subdued Egypt with no further resistance than that of the Greek garrison of Pelusium. Nekht-nebf, instead of endeavouring to relieve them, retreated to Memphis and fled thence to Ethiopia, B.C. 340? Thus miserably fell the monarchy of the Pharaohs after an unexampled duration of nearly 3000 years, or as some think far longer. More than 2000 years have since passed, and though Egypt has from time to time been independent, not one native prince has sat on the throne of the Pharaohs. "There shall be no more a prince of the land of Egypt" (Ezek. xxx. 13) was prophesied in the days of Apries as the final state of the land.

The causes of the downfall of Egypt are sufficiently evident in the previous history. The weakness of the later Thebans fostered divisions. The Bubastites aided the natural tendency of the country to break up into small principalities. The Ethiopians, while they brought a new force to resist the Assyrians, increased the divisions of Egypt, which had to choose to which of two foreign empires it would submit. The Saïtes restored nationality, but they maintained it at the cost of alienating the native troops, and thus could not effectually resist Persia. Although their gallant struggles brought out the fighting qualities of the Egyptians, these Pharaohs could never venture on a great war without Greek mercenaries. Hence constant discontent and an inharmonious military system. At length the native energy was worn out.

The barbarian Ochus used his success mercilessly, rivalling the worst acts of Cambyzes. Under him and his successors Egypt made no movement, and when Alexander entered the country as the conqueror of Persia he was welcomed as a deliverer. The Persian governor had not forces enough to oppose him, and he experienced nowhere even the show of resistance. He visited Memphis, founded Alexandria, and went on pilgrimage to the oracle of Jupiter Ammon. He then organized the government under two officers, who from their names appear to have been a Greek and an Egyptian. He left the Egyptians satisfied with his reverence for their religion, and for the rest of his reign the country remained a peaceful province of his great empire. With Alexander, the Macedonian dominion began. It lasted for 302 years, after the Empire the brightest period of Egyptian history, during the whole of which no general native revolt broke out. From this time the Egyptian local princes, who for five centuries, except only during the rule of Psametik and his house, had caused all the divisions of Egypt, disappear from the scene. This final settlement was probably due to the policy of Alexander, under whose successors we see the real government of the country, with its centre in the Greek city he had founded, and the control of the army and navy, intrusted to Greeks; whereas the native religion was protected, but wholly left to the Egyptian priests, except so far as the king himself acted as one of the priesthood. Thus the foreigners had all the true power, while the natives were satisfied with a semblance of it, and the local importance this semblance gave to their functionaries. Routes of trade were actively pushed, and works of public benefit carried out, and the Egyptians grew more and more

wealthy, in Egyptian towns, where a Greek was rarely seen, and the king only appeared in the character of a Pharaoh to show respect to the religion of the country. The learned men of both races drew nearer together, and Greek speculation had its effect on Egyptian thought. The less cultivated settlers were attracted by the native superstitions, and at last the Alexandrian was far more an Egyptian than even a Macedonian.

On the division of Alexander's dominions, Egypt fell to the share of Ptolemy, son of Lagus and Arsinoë, a concubine of Philip's, whose son he was supposed to have been. Of all Alexander's generals he was the most far-sighted. Instead of aiming at the rule of the empire, he secured the least exposed province and employed its resources rather for defence than offence. One of his first acts was to divert the burial of Alexander from Macedon to Egypt. The body was taken to Memphis, but under Ptolemy's successor it was removed to Alexandria, so that the conqueror rested in the city he had founded. His first conquest was the Cyrenaica (B.C. 322), a valuable province outside the field of the contests of his rivals, yet greatly useful for naval enterprises against them. Yet he did not declare himself independent; as a subject of the phantom kings Philip Arrhæus and Alexander Ægus, he inscribed their names in his restorations of Egyptian temples, and alone of all the generals struck money in the name of Ægus so long as that last heir of Alexander lived. He was not long left in undisturbed occupation of his government. The regent Perdiccas, finding that Ptolemy was engaged in a league against his authority, marched into Egypt, B.C. 321; but the resistance of Ptolemy and a mutiny in the invader's army, which resulted in his death, delivered Egypt from this danger. The succeeding years were occupied in attempts to add Cœle-Syria and Phœnicia to the Egyptian dominions, which can scarcely be considered rash when we remember the importance of these provinces to the security of Egypt against invasion, and for winning of the maritime supremacy of the eastern Mediterranean. During this time Cyprus was made a dependency, and the Cyrenaica, which had revolted, was finally reduced by Ptolemy's step-son Magas. A great calamity now arrested the growing power of Egypt, when Demetrius, son of Antigonus, defeated Ptolemy in a sea-fight off Salamis of Cyprus (B.C. 306). Antigonus then assumed the royal diadem, and Ptolemy followed his example. Antigonus and Demetrius immediately attacked Egypt, but without success; and Ptolemy, rapidly recovering his strength, aided the Rhodians when besieged by Demetrius (B.C. 305-4). It is related that when the siege was raised the Rhodians gave Ptolemy, as their "preserver," the title of *Σωτήρ*. This appears in his hieroglyphic inscriptions as his distinctive title, and upon the coins of his successors struck in his name in Phœnicia. After this Ptolemy again attempted without success the conquest of Cœle-Syria and Phœnicia, but ultimately seized and held Cyprus, B.C. 295, which thus became a part of the Egyptian monarchy for nearly its whole duration. His later years were passed in consolidating his power. Seleucus was master of a Syrian empire, too firmly ruled to be attacked with any chance of success, and stretching too far eastwards to make its master aggressive on the Egyptian border. The government of Egypt was assured by the care taken to maintain and increase the Greek element in the country. Alexandria was made a seat of Hellenic culture, and if it is not absolutely certain that Ptolemy founded the Library and the Museum, he undoubtedly gathered the necessary intellectual materials. The great Greek colony of Ptolemais, in the Thebais, was established. Thus the native and foreign elements were kept apart, conflicts avoided, and strong Hellenic centres secured. The

Egyptians were flattered by the arrival of the image of Sarapis from Sinope and the spread over Egypt, under the king's influence, of a Hellenic form of their religion. The king's portrait on his coins shows us him in old age, and is distinguished by resolution, keenness, and craft.

Having ruled thirty-eight years, the old king abdicated in favour of his young son Philadelphus, chosen to the prejudice of his elder brothers (B.C. 285), and died two years later (B.C. 283).

Ptolemy Philadelphus ruled for thirty-eight years of almost undisturbed peace. His half-brother Magas, probably soon after the death of Ptolemy Soter, declared himself king in Cyrenaica, and attempted to invade Egypt. Ptolemy remained on the defensive, and at last a treaty was signed by which Ptolemy, heir of the Egyptian crown, and Berenice, heiress of Cyrenaica, were betrothed, Magas retaining the power if not the name of king. Philadelphus was also fortunate in recovering Phœnicia and Cœle-Syria. This probably took place not much before B.C. 266, for that is the earliest date in the series of coins struck at Tyre during his reign. He secured the friendship of the Phœnician and Palestinian coast-towns, by granting them a degree of autonomy, for their coins, though dated in his reign, were struck at each town, and bear not his name but that of his father. In Egypt he paid great attention to the extension of commerce. He reopened the canal of the Red Sea and established a desert route from Coptos to Berenice on the coast which he had founded. He made war in Ethiopia, but according to his custom he was content to be on friendly terms with the Ethiopian king Ergamenes. His Ethiopian expedition led to his establishing a station for the purpose of securing a supply of elephants for war. An ambassador was sent to India. Thus the trade of Ethiopia, Arabia, and India was secured for Egypt, and continued to enrich it for eighteen centuries. Not less wisely Philadelphus made Alexandria, with the Museum and Library, the heart of the learning of Greece. Many cities were founded by him, or like Ptolemais in Galilee, refounded. In his long reign there was little expenditure but such as was calculated to enrich his empire. At his death his dominions equalled those of his father. He held Cyprus, much of the coast of Asia Minor, the Cyclades, and part of Ethiopia and Arabia. The Cyrenaica was only to be separated for the life of Magas. He twice married. His second wife was Arsinoë II, his full sister, whom he married in accordance with Egyptian rather than Greek notions. She was a woman of great beauty and force of character, and much loved by her husband. The character of Philadelphus is marked by the craft rather than the force of his father's; but he inherited to the full his love of literature and his love of pleasure, both undisturbed by warlike ambition. He is the last representative of the old Greek "tyrannos," whom Pindar has made known to us, rather than one of the restless "diadochoi."

Ptolemy Energetes, son of Philadelphus and Arsinoë I, by his accession, B.C. 247, reunited the Cyrenaica to the Egyptian empire. A quarrel between Egypt and Syria immediately broke out. The Syrian king Antiochus II. had married a daughter of Philadelphus. She was now put away, and, as well as Antiochus, murdered by her rival, his first wife Laodice, who set up her son Seleucus II. Ptolemy invaded Syria, which he speedily subdued, and then following the traditions of Egyptian conquest, he passed the Euphrates and reduced the whole of the eastern dominions of Seleucus. He returned to Egypt with vast treasures, including the statues of the gods which Cambyses had carried away, and which he restored to the temples. At sea he was equally fortunate, and the maritime territories of Egypt in the eastern Mediterranean were greatly enlarged. For a moment the old Egyptian Empire was again revived

in larger proportions, extending from the Thracian coast to Ethiopia, from Cyrene to the border of India. The eastern provinces speedily returned to the Syrian rule, and Ptolemy was content with a moderate accession of territory on that side. He, however, retained his Greek conquests and pushed far south in Abyssinia. Euergetes was not merely a warlike king. He cared for literature, and more than his predecessors laboured to please the Egyptians. He is the first Ptolemy whose Egyptian structures are worthy of the wealth of the country. Art had lost its ancient delicacy, yet the sumptuous architecture of this age merits admiration as showing a new though somewhat false development of the ancient style. His reform of the native calendar, as recorded in the Decree of Canopus, is another mark of his wise interest in Egypt. He was fortunate in his marriage with Berenice II., who as queen of Cyrene is the first Egyptian queen who has the same regal style as her husband. Having reigned twenty-five years he left his kingdom to his son.

Ptolemy Philopator, who began to reign B.C. 222, immediately on his accession put his mother Berenice and others of his nearest kindred to death, and, leaving the management of the state to Sosibius, abandoned himself to luxury. Antiochus III., king of Syria, seized the opportunity to wrest from Egypt all the eastern provinces. Ptolemy at length took the field himself in defence of Egypt, and defeated Antiochus at Raphia, where his success was greatly due to the courage of Arsinoë III., his sister and wife (B.C. 217). By this victory Coele-Syria and Phœnicia were recovered. Ptolemy returned to his former life, and Arsinoë was put to death. He left his kingdom, greatly weakened by bad administration and growing disaffection, to a child, Ptolemy Epiphanes. The other two Macedonian kings, Philip V. and Antiochus III., now allied themselves to despoil Egypt of the provinces. Everything but Cyprus and Cyrene was taken, and the Egyptian ministers only saved the country by having called in the aid of Rome. The Republic had long been friendly to the Ptolemies, and nothing suited her policy better than a protectorate of Egypt. Accordingly M. Æmilius Lepidus was sent as regent to Alexandria, and Antiochus was commanded to restore what he had conquered. It was finally settled that Ptolemy should marry Cleopatra, daughter of the Syrian king, and that she should take back Coele-Syria and Phœnicia. From this time Rome ruled Egypt with reference to her own eastern policy. The kingdom of the Ptolemies was not allowed to fall, but it was kept within the most moderate limits. Consequently the weak kings were supported and the strong kings thwarted in every way. Egypt could not rid herself of a bad ruler or enjoy the full advantage of a good one. The rest of the minority of Ptolemy was marked by a serious revolt in Lower Egypt, put down with great difficulty. In B.C. 196, when but thirteen or fourteen years old, the young king was crowned at Memphis, when the decree of the Rosetta Stone was issued. The place of coronation and the terms of the decree show a policy of conciliation towards the Egyptians which the revolt probably rendered especially necessary. The marriage of Ptolemy and Cleopatra I. took place B.C. 193-2, but the dowry was not handed over. Ptolemy continued true to the Romans in their war with Antiochus, but was not allowed to act as their ally, and gained nothing in the subsequent treaty. Another revolt broke out in Lower Egypt, and was cruelly suppressed, B.C. 185. Ptolemy perished by poison in B.C. 181, leaving two sons surnamed Philometor and Euergetes, who ruled Egypt in succession. Epiphanes inherited the weakness and cruelty of his father, and with him Egypt lost for a time her influence in the affairs of the world.

Cleopatra I., who like Berenice II. was queen as heiress,

now became regent for Ptolemy Philometor, and ruled well until her death, about B.C. 174. The ministers then made war on Antiochus IV. (Epiphanes) for the disputed provinces. The Egyptian forces were defeated, Egypt invaded, and Ptolemy seized (B.C. 170). His younger brother, Euergetes II., with an audacious courage that marks his whole career, declared himself king at Alexandria, where Antiochus besieged him in vain, and Roman ambassadors interfered for his protection. Antiochus retired, leaving Philometor as king at Memphis. The two brothers now made terms, agreeing to a joint rule. Antiochus again invaded Egypt, and marched to Alexandria, but was forced to retire by the resolution of a Roman ambassador, M. Popilius Lænas (B.C. 168). From this time Egypt was more than ever in the hands of the Romans, and in consequence of the manner in which Philometor had yielded to Antiochus while Euergetes had resisted his pretensions and depended on their support, we find them constantly aiding Euergetes, whose abilities, if equal to those of Philometor, were weighted by a perfidious and cruel disposition. It was not long before Euergetes succeeded in driving Philometor from Alexandria. The fugitive went to Rome B.C. 164, and the senate agreed to reinstate him. Euergetes was spared by his brother, and the Roman deputies obtained for him the kingdom of Cyrene, where he occupied himself in ceaseless plots to obtain Cyprus, assisted by the active support of Demetrius I. of Syria and the unjust diplomatic aid of the Roman senate. Philometor had the courage to oppose his brother, who invaded Cyprus with Roman ambassadors ordered to settle him in the government of the island. Philometor defeated and took him prisoner, but again spared his life, and left him the kingdom of Cyrene (B.C. 154). The Romans did not interfere with this settlement.

The part Demetrius I. had played in the war in Cyprus led Philometor to take the side of the usurper Alexander I. (Balas), to whom he gave his daughter Cleopatra to wife (B.C. 150). When Demetrius II. endeavoured to recover his father's kingdom Ptolemy advanced to the support of Alexander, but thinking him treacherous, he turned his arms to the aid of the legitimate king. Rapidly subduing the country, Ptolemy entered Antioch and was hailed king of Syria, to the crown of which he had a claim as descended maternally from the Seleucid line; but he admitted the higher right of Demetrius, whom he aided in resisting an invasion by Alexander. In a decisive victory Ptolemy was thrown by his horse and mortally injured (B.C. 146).

It was in the reign of Philometor that Onias founded the temple at Onion in Egypt, which tended to increase the importance of the Jewish colonies and to separate the Alexandrian from the Palestinian school.

With this king the power of Egypt finally fell. He was the last Ptolemy who had the capacity to rule amidst the growing difficulties of the time. In his wars he showed courage and generalship, in his dealings with Rome caution and decision, in his rejection of the Seleucid diadem moderation and justice, in his treatment of his brother and his subjects an extraordinary clemency and humanity.

Cleopatra II., the sister and widow of Philometor, put their son on the throne.¹ Euergetes at once marched from Cyrene to Alexandria. The Romans as usual took his part, and stopped the war on the condition that Euergetes should marry his brother's widow. The young king was instantly put to death. Ptolemy reigned as he had begun: Alexandria was depopulated by his cruelties, though the rest of Egypt seems to have fared better in consequence of his want of ambition. He divorced Cleopatra II. to

¹ There is difficulty as to his name. In Egyptian documents Eupator precedes or follows Philometor (Lepsius, Berl. Akad. 1853, 464, *seqq.*); but in a Greek inscription in Cyprus the later place is stated (Hogg, J., "Inscr. from Cyprus," *R. S. Lit.*, 2 ser., vii 387, *seqq.*).

marry her daughter, his niece, Cleopatra III. In B.C. 130 he was driven out of Egypt by a revolt, and Cleopatra II. became queen. In revenge he put to death their son. Cleopatra having asked the aid of Demetrius II., Ptolemy was recalled, B.C. 127, and for the rest of his reign adopted a more conciliatory policy. He engaged in war against Demetrius II., and supported the usurper Alexander II., against whom he subsequently turned, apparently with reason. The reconciliation with the Seleucids led to the recall of Cleopatra II., with whom Ptolemy now reigned. He died B.C. 117, in the fifty-fourth year from his first accession. This king, the worst of the Ptolemies, as Philometor was the best, is significantly known by the nickname Physcon, or Fat-paunch, but he was also called by his subjects the Ill-doer, Kakergetes, instead of the Well-doer, Euergetes. Some of his latest coins present, instead of the idealized head of Ptolemy, the founder of the line, bloated and cruel features which can only be those of Physcon. His one good quality was a hereditary love of letters.

Cleopatra III., surnamed Cocce, widow of Euergetes and heiress of Philometor, succeeded, and, in deference to the popular will of the Alexandrians, associated with her Ptolemy Soter II., surnamed Lathyrus, or Lathyrus, her elder son, instead of Ptolemy Alexander I., the younger, whom she preferred. They ruled together with little concord, and at length Cleopatra expelled her colleague, who had been the real sovereign, and recalled Alexander from Cyprus, where he had already ruled independently for seven years (B.C. 107). Cyrene was probably lost to Egypt about this time. Physcon had left this kingdom to his base son Ptolemy Apion, who is generally supposed to have at once succeeded. The coins, however, show that the latest Cyrenaic coinage of Physcon was continued by Lathyrus. Cleopatra III. now ruled with a stronger authority, but by degrees Alexander gained the upper hand, and ultimately dissensions arose which ended by his causing her death (B.C. 89): this occasioned troubles which lost him his throne, and brought about the recall of his brother (B.C. 89). During the interval Lathyrus had ruled in Cyprus, and both brothers had engaged on opposite sides in the wars of the Seleucid princes. As king of Egypt, Lathyrus had to subdue a native revolt, the first we know to have happened in Upper Egypt in the time of the Ptolemies. Thebes seems to have been its centre, and here the insurgents stood a siege of nearly three years, when the city was taken and reduced to the ruined state from which it has never since risen. Lathyrus died in B.C. 81. He appears to have been weak and cruel, with some qualities as a politician and general. He left one legitimate child, a daughter, Berenice III., who succeeded him. Her step-son, Alexander II., son of Alexander I., came from Rome as Sulla's candidate, and married her. The nuptials were almost immediately followed by the murder of the queen by her husband's order, and his deserved death in a popular tumult which was thus excited (B.C. 80). In default of legitimate issue, two base sons of Lathyrus now shared the Egyptian dominions, the elder, Ptolemy Neus Dionysus, surnamed Auletes, the Flute-player, taking Egypt, and his younger brother Ptolemy acquiring Cyprus. Auletes inherited the vices without the ability of Physcon, and having spent great sums in obtaining the recognition of the senate, who probably would not readily part with the claim based on the legacy which either Alexander I. or II. had made of his kingdom to the Romans, he wearied the patience of his subjects by heavy taxation, and was expelled by the Alexandrians B.C. 58. His wife Cleopatra V. and daughter Berenice IV. now reigned together, but, on the death of the elder, the younger became sole queen. Berenice was twice married, first to Seleucus, a pretended Seleucid,

whom she put to death, and then to Archelans. With the support of Gabinus, proconsul of Syria, Auletes at length recovered Egypt, B.C. 55. He punished his daughter with death, and in B.C. 51 his troubled reign came to an end. At this time his family consisted of two sons and two daughters,—the famous Cleopatra and Arsinoë, all of whom in turn exercised regal power, three in Egypt.

Ptolemy, the elder son of Auletes, and Cleopatra VI., his elder daughter, succeeded in accordance with their father's will, which the Roman senate ratified. In B.C. 48 her brother expelled Cleopatra, who fled into Syria. Advancing to conquer Egypt by force of arms, she was met by her brother's forces near Pelusium. Here it was that Pompey, after the ruin of his cause, was assassinated by order of Ptolemy's ministers as he sought the king's protection. Caesar, following Pompey, reached Alexandria. Here Cleopatra, giving up her ideas of war, made her way to Caesar and secured his interest. After a struggle with the Egyptian ministers, who almost succeeded in overpowering Caesar's small forces, and who ultimately had the support of young Ptolemy, who escaped from the Romans, the Egyptians were defeated and the king drowned (B.C. 47). Cleopatra now became queen, associated with a phantom king, the younger Ptolemy. In B.C. 45 she went to Rome with her brother and young Ptolemy Caesar, her son by the dictator, wishing to be acknowledged Caesar's wife, and that the boy should be made his heir. Next year Caesar was murdered, but by his will his nephew Octavius became his heir, Cleopatra's son, his only surviving child, being necessarily set aside. The queen determined to secure for her son Egypt at least, and made away with her unfortunate brother. She next appears when, after the battle of Philippi, the triumvir Antony made his progress through Asia Minor. It was necessary that the queen of Egypt should conciliate the ruler of the Eastern world. Cleopatra resolved to govern him. As Caesar seven years before, Antony now was instantly captivated by the Egyptian queen. She was past thirty, but if her beauty had waned her wit had grown. Her portrait on her coins is that of a woman of intellect and charm, not of beauty. A broad head with wavy hair, an aquiline nose, large deep-set eyes, and a full eloquent mouth, is supported by a long slender throat. To these personal qualities she added a mind singularly cultivated, ready discourse in several languages, and, what that so often lacks, as ready wit. She took Antony to Alexandria and governed the East for him. While her power waxed his waned. Asia Minor was overrun by Q. Labienus at the head of a Parthian army, and Palestine and Phœnicia by another led by Pacorus, the Parthian king's son. In Italy Antony's adherents were routed. He now resolved to attack Italy itself, and a great war was only averted by the armies, which forced the generals to conclude a peace (B.C. 40). Octavia, his rival's sister, was given in marriage to Antony, and for three years Cleopatra lost her power. In B.C. 36 Antony deserted Octavia and returned to Alexandria and the Egyptian queen. With the exception of an unsuccessful Parthian campaign and an inglorious Armenian one, Antony effected nothing. He was amused by the luxurious life of Alexandria; and, while Cleopatra maintained her Egyptian rights and ruled with Ptolemy Caesar, she shared Antony's government of the East, appearing as queen with him as triumvir upon the coins of Antioch. In B.C. 32 Octavian declared war against Cleopatra, and Antony took his revenge by divorcing Octavia. Then followed the conflict in the Adriatic for the world's empire, in which Antony's old military skill failed him, and Cleopatra, leaving the battle, perhaps through a woman's fear, drew him away also (B.C. 31). Arrived at Alexandria, Cleopatra showed more energy than Antony, and, when Octavian reached

Egypt, more policy. Antony, on the false news of the queen's death, stabbed himself; and Cleopatra, finding Octavian resolved to make her walk in his triumph, perished by her own hands in some unknown way. Thus Egypt became a Roman province, B.C. 30. The young Ptolemy Caesar, in spite of his double claim, perished by the command of Octavian, but the beautiful Cleopatra, Antony's daughter by the queen, was generously taken by his divorced wife Octavia, brought up with her own children, and married to a king, Juba II. of Mauretania. With their son Ptolemy, whom Caligula put to death A.D. 40, this great line came to an end. Its genius ended with Cleopatra. The dislike of the Romans for her has tended to give the moderns too low an estimate of her abilities. When we see what Egypt was under Auletes and under her we are astonished to perceive how much she accomplished by her management of Caesar and of Antony. After all the other independent states had been absorbed by Rome, Egypt was raised from a mere protected province to be once more a kingdom, and at last Alexandria became again a seat of empire. But the task Cleopatra set herself was beyond accomplishment; the more she turned Antony into an imperial ruler the less could he control the Roman armies by which he governed. Thus the fabric she had raised was rotten at the base, and with her fall it disappeared.

The history of Egypt under the Romans being that of a province, and the most interesting events matters of ecclesiastical history, may here be told very briefly. Worn out by the cruelty and avarice of a succession of bad rulers, the country must have welcomed the Romans almost as it had welcomed Alexander, and so soon as it was known that the native religion would be protected, all discontent must have vanished. The temples were still the care of the rulers. Art had indeed fallen very low, yet it continued to produce buildings with a certain rich grandeur, that did not begin to give place to Græco-Roman structures till the time of Hadrian and the Antonines.

Ælius Gallus, prefect of Egypt under Augustus, was ambitious to enlarge the province by foreign conquest. He failed in an expedition into Arabia Felix, but repelled an Ethiopian invasion, and in return penetrated as far as Napata, the capital of Queen Candace, which he captured. In later reigns the chief events were troubles connected with the Jewish population. In the time of Vespasian, the temple on Masada had founded was closed, and a great Jewish revolt in the reign of Trajan, which was not easily suppressed, cost the Jews the privileges which, in common with the Greek population, they had enjoyed above the native inhabitants. Hadrian twice visited Egypt (A.D. 130, 134). He renewed the old privileges and granted new ones. The foundation of Antinöe shows how low the nation had then fallen. Under Antoninus Pius, a Sothiac Cycle began (A.D. 139). In the next reign, Avidius Cassius, prefect of Egypt, having suppressed a serious revolt, usurped the purple, and was acknowledged by the armies of Syria and Egypt. On the approach of Marcus Aurelius, the adherents of Cassius slew him, and the clemency of the emperor restored peace. After the downfall of the house of the Antonines, Pescennius Niger, who commanded the forces in Egypt, was proclaimed emperor on the death of Pertinax (A.D. 193). Severus overthrew his rival (A.D. 194), and, the revolt having been a military one, did not punish the province, but gave great privileges to the Alexandrians. In his reign the Christians of Egypt suffered the first of their many persecutions. When Christianity was planted in the country we do not know, but it must very early have gained adherents among the learned Jews of Alexandria, whose school of thought was in some respects ready to welcome it. From them it rapidly passed to the Greeks. Ultimately, the new religion spread to the Egyptians, their own creed was worn out, and they found in Christianity a doctrine of the future life, for which their old belief had made them not unready, while the social teaching of Christianity came with special fitness to a subject race. The history of the Coptic Version has yet to be written. It presents some features of great antiquity, and, unlike all others, has the truly popular character of being written in the three dialects of the language. Side by side there grew up an Alexandrian Church, philosophic, disputative, ambitious, the very centre of Christian learning, and an Egyptian Church, ascetic, contemplative, mystical. The two at length influenced one another; still we can generally trace the philosophic teachers to a Greek origin, the mystics to an Egyptian.

Caracalla, in revenge for an affront, massacred the population of Alexandria. Under Decius the Christians again suffered from persecution. When the Empire broke up in the weak reign of Gallienus, Æmilianus was made emperor by the troops at Alexandria,

but, after a short and vigorous reign, was conquered by the forces of Gallienus. Zonobia, queen of Palmyra, after an unsuccessful invasion, on a second attempt conquered Egypt, which she added to her empire, but lost it when Aurelian made war upon her (A.D. 272). The province was, however, unsettled, and the conquest of Palmyra was followed in the same year by the suppression of a revolt in Egypt (A.D. 273). Probus, who had governed Egypt for Aurelian and Tacitus, was subsequently chosen by the troops to succeed Tacitus, and is the first governor of this province who obtained the whole of the Empire. The country, however, was still disturbed, and under the reign of Diocletian, in A.D. 292, a formidable revolt had broken out, led by Achilleus, who as emperor took the name Domitianus Domitianus. Diocletian, finding his troops unable to determine the struggle, came to Egypt and reduced the strongholds of the country. After he had left, Domitianus again raised his standard and captured Alexandria, but Diocletian returning to Egypt took the city and put his rival to death (A.D. 297). This revolt has very distinctly the character of a native rising, for it was not localized in Alexandria, but spread over the country.

The reign of Diocletian is the turning-point in the history of the Egyptian Church. The edict of A.D. 303 against the Christians, and those which succeeded it, were rigorously carried out in Egypt, where Paganism was still strong, and face to face with a strong and united church. Galerius, who succeeded Diocletian in the government of the East, implacably pursued his policy, and this great persecution did not end until the persecutor, perishing, it is said, of the dire malady of Herod and Philip II. of Spain, sent out an edict of toleration (A.D. 311). The Copts date from the accession of Diocletian (A.D. 284), which they call the Era of Diocletian or of the Martyrs.

By the Edict of Milan (A.D. 313), Constantine, with the agreement of his colleague Licinius, acknowledged Christianity as having at least equal rights with other religions, and when he gained sole power he wrote to all his subjects advising them, like him, to become Christians (A.D. 324). The Egyptian Church, hitherto free from schism, was now divided by a fierce controversy, in which we see two Greek parties, rather than a Greek and an Egyptian, in conflict. The Council of Nicæa was called together (A.D. 325) to determine between the orthodox and the party of the Alexandrian presbyter Arius. At that council the native Egyptian bishops were chiefly remarkable for their manly protest against enforcing celibacy on the clergy. The most conspicuous controversialist on the orthodox side was the young Alexandrian deacon, Athanasius, who returned home to be made archbishop of Alexandria (A.D. 326). For the long period during which he presided over the Church of Egypt, his history is that of the struggle of the two parties. Four times expelled by the Arians, and once by the emperor Julian, he employed each banishment for work in the cause to which he was devoted, and on each restoration he used his success with a moderation in marked contrast to the persecuting policy of his enemies. His name and person were at last known to the whole empire, which unconsciously recognized in him an ecclesiastical ruler of Christendom, rather than the chief prelate of a province. He was more a man of action than of thought, more an administrator than a student, but his intrepid patience, his moderation, and his indomitable energy, all directed to the welfare of the church and to no personal ends, gave him an influence never afterwards obtained without the support of a vast ecclesiastical machinery. His is the latest character which was formed upon the model of St Paul's, and the most remarkable of his age. He died A.D. 373, at the moment when an Arian persecution began. The reign of Theodosius I. witnessed the overthrow of Arianism, which was followed by the suppression of Paganism, against which a final edict was promulgated A.D. 390. In Egypt, the year before, the temple of Sarapis at Alexandria had been destroyed, and to the same period we must assign the beginning of a partial destruction of those Egyptian temples which had escaped the Persian conquerors. Generally the Coptic Christians were content to build their churches within the ancient temples, plastering over or effacing the sculptures which were nearest to the ground and in the way of the worshippers. They do not seem to have been very zealous in the work of destruction. The native religion was already dead and they had no fear of it. The prosperity of the church was the sign of its decay, and before long we find persecution and injustice disgracing the seat of Athanasius. Cyril the patriarch of Alexandria expelled the Jews from the capital with the aid of the mob, and by the murder of the beautiful philosopher Hypatia marked the lowest depth to which ignorant fanaticism could descend. A schism now produced lengthened civil war, and alienated Egypt from the empire. The Monophysites, after a struggle of two centuries and a half, became utterly hostile to the Greek rule. It was in these circumstances that a country which, remote from the great conflicts that destroyed the Western Empire and threatened the existence of the Eastern, had enjoyed uninterrupted freedom from an invader since its conquest by Zonobia, and had known no rebellion since that of Achilleus, fell without a

conflict when attacked by Chosroes (A.D. 616). The success of Heraclius restored Egypt to the Empire and for a time it again received a Greek governor. The Monophysites, who had taken advantage of the Persian occupation, were persecuted and their patriarch expelled. The Arab conquest was welcomed by the native Christians, but with it they ceased to be the Egyptian nation. Their language is still used in their churches, but it is no longer spoken, and its literature, which is wholly ecclesiastical, has been long unproductive.

The decline of Egypt was due to the purely military government of the Romans, and their subsequent alliance with the Greek party of Alexandria which never represented the country. Under weak emperors, the rest of Egypt was exposed to the inroads of savages, and left to fall into a condition of barbarism. Ecclesiastical disputes tended to alienate both the native population and the Alexandrians. Thus at last the country was merely held by armed force, and the authority of the governor was little recognized beyond Alexandria, except where garrisons were stationed. There was no military spirit in a population unused to arms, nor any disinclination to be relieved from an arbitrary and persecuting rule. Thus the Muslim conquest was easy.

[In the year 639 of our Era, or the eighteenth of the Flight,¹ Egypt was invaded by the Muslims, under the celebrated 'Amr Ibn-El-As (or El-Asee). Entering the country from Syria, at the head of only 4000 men, he besieged Pelusium, and took it after thirty days. This town was considered the key of Egypt on the Syrian frontier, and its capture was, therefore, an important advantage, which opened the country southwards to the Arab general. He marched thence to 'Eyn-Shems, the ancient Heliopolis, where he found the Greeks collected in force, and commanded by John Mukowkis, or rather John the Mukowkis, or Gureyg the Mukowkis,² the governor of Memphis, a native Egyptian. They offered a vigorous defence, but were put to the rout, and 'Amr advanced to the banks of the Nile and laid siege to Egyptian Babylon, a fortress of great strength, and garrisoned by a Roman legion. Here he received two reinforcements of 4000 Muslims each, and after a protracted siege of seven months he took the place by assault. In an enemy's country, and far from all supplies, the small army of the Arabs was still in a critical position and unable to push on against the capital, Alexandria, when the enmity of rival Christians and the perfidy of Mukowkis decided the balance in their favour. The persecutions which the Copts had suffered had greatly embittered them against the Greeks, and, as Gibbon observes, had "converted a sect into a nation, and alienated Egypt from their religion and government." Mukowkis, who governed Memphis, was in heart a Monophysite, and had also withheld the tribute due at Constantinople; and both he and his Coptic brethren, after the first resistance, hailed the new invaders as their deliverers from the Greek yoke. On the fall of Babylon they entered into

¹ The years of the Muslim era, the Hyrah, or Flight of Mohammad from Mecca, are generally used in this portion of the history, as they are more convenient to Oriental scholars. The principal dates are, however, given according to both methods of computation.

The authorities upon which this sketch of the history of Egypt under Muslim rule is based are these:—Eutychius, *Annales*, the *Kāmil* of Ibn-el-Atheer (ed. Tornberg); Abu-l-Fidā, *Annales Muslemica* (ed. Reiske); El-Makreeze's *Khutat*; El-Ishākee (MS.); Ab-ul-Mahāsini; Ibn-Khalikān's *Biogr. Dict.* (trs. De Slane); Es-Sayootee's *Kitāb Husn el-Mohādarah* (MS.) and *Ta-reekh El-Khulafā*; El-Makreeze's *Kitāb-es-Sulook* (trs. Quatremère); Bahā-ed-Deen's *Vita Salādini* (ed. Schultens); El-Gabartee's *Annals* (MS.); Wüstenfeld's *Die Statthalter von Aegypten zur Zeit der Chalifen* (1876); Weil's *Geschichte der Chalifen*; Quatremère's *Vie de Moazz-li-din-Allah*, and *Mémores géogr. et hist. sur l'Égypte*; Michaud's *Hist. des Croisades*; Joinville's *Vie de Saint Louis*; Marcel; Mongin's *Hist. de l'Égypte*; Sir R. Wilson's *History of the British Expedition*; Lane's *Modern Egyptians*; Mrs Poole's *Englishwoman in Egypt*; McCoan's *Egypt as it is*, &c.,

² Mukowkis, meaning a kind of ring-dove, seems (according to the *Kāmoos*) to have been the symbol of the governor of Egypt under the Greeks, just as the hawk was the symbol of the Pharaohs. Gureyg may also be written Jureyy, but the former, representing the Egyptian pronunciation of the letter *j*em, is preferred in this article in this and similar instances.

a treaty with the Arabs, engaging to pay to them a poll-tax of two deenārs on every adult male, and agreeing to furnish them with supplies and assistance while completing the subjugation of the country. Having concluded this treaty, and founded the city of El-Fustāt on the site of his first encampment on the banks of the Nile, with the mosque known by his name, 'Amr marched against Alexandria; and after overcoming many obstacles, and disputing the whole way with the Greeks, who conducted their retreat, in the face of a victorious army, with great ability, in twenty-two days he appeared before it. Fresh warriors continued to arrive from Syria to strengthen the besieging force; but the defence was as obstinate as the attacks of the Muslims were brilliant, and was protracted for fourteen months. At length, on the 10th December 641, the metropolis of Egypt, the first city of the East, capitulated; but it is said that this conquest was only achieved with the sacrifice of 25,000 Muslims. Abu-l-Farag relates that 'Amr, wishing, at the earnest request of John the Grammarian, to spare the famous Library, wrote to the caliph (Khaleefah) Omar, asking his instructions respecting it, and that he answered: "As to the books you have mentioned, if they contain what is agreeable with the book of God, in the book of God is sufficient without them; and if they contain what is contrary to the book of God, there is no need of them; so give orders for their destruction." The historian adds, that they were burnt in the public baths of the city, and in the space of six months were consumed.³ The conquest of the rest of Egypt was soon effected, and the various strongholds successively fell into the hands of the invaders.

'Amr governed the country with much wisdom for four years, but was dismissed by 'Othmān, who appointed in his place 'Abd-Allah Ibn-Saad Ibn-Abee-Sarh. The latter reduced Alexandria, which had been retaken by the emperor Constans II, and pushed his conquests beyond Africa Proper. He died at Ascalon, in the year 36, having governed eleven years. His successor's rule was short, and the next viceroy, Mohammad, son of the caliph Aboe-Bekr, on assuming the reins of government acted with such tyranny towards the followers of 'Othmān, that Mu'awiyeh was compelled to dispatch 'Amr to Egypt with a force from Syria, and a great battle was fought in A. H. 38 between the two armies of Muslims, in which 'Amr was again victorious. As a reward for this service, he was a second time appointed governor of Egypt, and he died there at the age of ninety years, in A. H. 43.

From this time to A. D. 868, or for rather more than two centuries, Egypt was governed by a succession of viceroys, appointed by the caliphs of Damascus and Baghdad. Their period was distinguished by intestine troubles and a constant change of rulers, resulting from the caprice of the caliphs or the vicissitudes of their fortunes. Here we may mention, that shortly after the overthrow of the Amawee ("Ommiade") Dynasty of Damascus, and the accession of the house of 'Abbās, which ruled at Baghdad, the city of El-'Askar, immediately to the north-east of El-Fustāt, was founded, and the seat of government removed thither. The site is without the walls of modern Cairo, and is marked by extensive mounds of rubbish.

In A. D. 868 (A. H. 254) Ahmad, the son of Toeloen, a Turkish slave who held a high office at Baghdad, was appointed governor of the province of Misr by the caliph El-Moatezz, and two years after of that of Alexandria also, by his successor El-Muhtadee. His temporal allegiance to the caliph soon became merely nominal, and he was virtually sovereign of Egypt; but at the same time he endeavoured to avoid a complete rupture by continuing the prayer for the Prince of the Faithful in the mosques, and the mention of his name on the coins which he struck. Later in his reign, however, he forbade the mention of the next caliph's brother and colleague El-Muwaffik in the prayers and state-documents of Egypt, and El-Moatemid, who was a weak prince, was prevailed on to denounce

³ This tradition is, we believe, only mentioned fully by Abu-l-Farag, but he was a Christian, and Muslim writers would consider it an occurrence of no importance. Abd-el-Lateef merely says, "Here was the library which 'Amr Ibn-El-As burned by permission of Omar;" and El-Makreeze, speaking of Pompey's Pillar, says, "It is said that this pillar is one of those which stood in the portico of Aristotle, who there taught philosophy, and that his academy contained a library which 'Amr Ibn-El-As burned by direction of Omar." See *Englishwoman in Egypt*, vol. i. 40, *seq.*

him publicly as a traitor from the pulpits throughout his dominions. Yet that he secretly favoured him is proved by his vain attempt to escape to Egypt from the tyranny of his warlike brother Ahmad founded the dynasty of the Bence-Tooloon, which lasted for a period of 37 years. He built the royal city of El-Katâf, between El-'Askar and Monnt Mukattam, enriched it with splendid buildings, and constituted it the seat of his government. Its site is now covered with ruins, only his great mosque remaining a proud example of his wealth and magnificence, still the largest mosque of Cairo, and, as presenting the earliest specimens of the pointed arch, noteworthy in the history of architecture. The reign of this vigorous and wise prince was remarkable for prosperity at home and conquests abroad. He took Barkah, and in Syria in 264 captured Damascus, Hims (Emessa), Hamâh, and Aleppo; after which he proceeded to Antioch, and the governor refusing to surrender, he took that city by storm. He then advanced towards Tarsus, but his supplies failing he was compelled to retire. About five years later, Lu-lu, his deputy and governor of Aleppo and other towns in Syria and in Mesopotamia, revolted and entered into a league with El-Muwaffik. It was apparently after an expedition against this rebel that Ahmad died, in the year 270 (A.D. 884). During the latter years of his reign, he had abandoned that simplicity of life which had distinguished his youth, and had given himself up to boundless luxury. At his death, there was found in his treasury ten millions of denârs, and his establishment was discovered to consist of 7000 mounted memlooks, 300 picked horses for his own use, a body-guard of 24,000 slaves, besides 6000 asses and mules, 10,000 camels, and 100 wherries. By what oppression the revenue necessary to maintain such a household was raised some idea may be formed, when it is stated that at the time of his death 18,000 persons were confined in Ibn-Tooloon's prisons.

Khumaraweyh, on the death of his father, was appointed his successor by the army, he being then twenty years old, and he inherited a kingdom extending from the Euphrates to Nubia. He fought a battle with the forces of the caliph, commanded by a son of El-Muwaffik (afterwards the caliph El-Moatadid), between Damascus and Rameleh, in which his army gained the victory, although he himself, never having seen a battle before, fled the scene of action in a panic, drawing a large part of his troops after him. But he soon reversed the independent policy of his father, and making peace with the caliph in 278 he not only put the latter's name with that of his brother El-Muwaffik in the public prayers, but entirely omitted his own, though it must be allowed he did not pursue the same servile course in his coinage. On the accession of El-Moatadid in 279, Khumaraweyh continued his conciliatory policy and offered his daughter Katr-en-Nedh (Dewdrops) in marriage to the caliph's son. In 282 he made an incursion into the Greek territory, and died at Damascus. It is said that he was fearful of assassination, to avoid which he had trained a lion to guard him while he slept on his bed of quicksilver. His fears were justified, for he was put to death by his women, or according to some by his eunuchs.

His eldest son, Geysh Abu-l-'Asâkir, not yet fourteen years old, succeeded him. This prince was killed in less than eight months. His youth, which rendered him unfit to govern, occasioned his fall, for he had discarded from his society those who were in favour with his father, and associated with none but worthless men. He was succeeded in 283 by his brother Hâroon, the principal events of whose rule were a great tempest and earthquake in Egypt in 286, and a treaty which he concluded with the caliph, by which the provinces of Awâsim and Kinnerreen were ceded to him and the annual tribute from Egypt was fixed at 450,000 denârs. He reigned upwards of eight years, but gave himself up to pleasure, and, as some say, was put to death in 292 by his uncles Sheybân and Ade'e, sons of the founder of the dynasty, the former of whom succeeded to the government. In the meantime, at the instigation of the generals of Hâroon, Mohammad Ibn-Suleymân, a scribe of Lu-lu, advanced against Egypt with a numerous and heavily equipped army. Sheybân went forth to meet him with all the forces he could muster, but numbers of his troops deserted to the invader, and he was soon compelled to surrender. Mohammad Ibn-Suleymân burned El-Katâf, and sacked El-Fustât, reducing the women to slavery, committing many atrocities, and exiling the family of Ahmad Ibn-Tooloon, with all their adherents (A.H. 292, A.D. 905).

Having thus completed his conquest, and restored the province of Egypt to the house of 'Abbâs, Ibn-Suleymân yielded the government to 'Eesâ En-Nôsharee, appointed by El-Muktefee. He died in 297, and was followed by Tekeen El-Gezeere, under whose rule Egypt was invaded by the forces of 'Obeyd-Allah El-Mahdee, first prince of the dynasty of the Fâtîmees, which had succeeded the Bence-l-Aghlab in the dominion of Northern Africa. His general Hubashch, having taken Barkah, advanced (in 302), with an army of 100,000 men, to Alexandria, which he found deserted, and thence marched to the Feiyoöm, where Tekeen, reinforced with troops from El-Irak, gave battle, and defeated the enemy in a sanguinary conflict. In the following year, he was succeeded by Abn-l-Hasan Zeke'e Er-Roomee, in whose time El-Mahdee again attempted the conquest

of Egypt with an army under the command of his son, Abn-l-Kâsim; Alexandria fell into his hands in 307; its inhabitants fled, and Zeke'e entrenched himself in El-Gezeeh, on the western bank of the Nile, and shortly afterwards died. In this emergency Tekeen was reinstated in his office, and a fleet of twenty-five sail was sent from Tarsus by the caliph, which meeting with the flotilla of the enemy off Resheed almost annihilated it. Tekeen, meanwhile, had defeated the Africans, but without decisive effect. At length, being twice reinforced from Baghdad, he drove Abu-Kâsim back to Barkah. After rendering this important service Tekeen was again recalled. Three other governors were then successively appointed, but the troops revolting, and much sedition and rapine ensuing, Tekeen was once more despatched to Egypt, where he remained until his death in the year 321 (A.D. 933).

He was followed by Abou-bekr Mohammad El-Ikhsheed Ibn-Taghagh, afterwards the founder of the dynasty of the Ikhsheedes, who was almost immediately superseded by another governor; and for one year more Egypt continued to be a province of the caliphs of Baghdad. In the year 323, El-Ikhsheed again succeeded to the government. About this time little remained to the caliph of his once broad empire beyond the province of Baghdad, and even there his power was but nominal. Khurasân, Fars, Karman, Rei, Ispahân, Mosul, and the provinces of Mesopotamia, were either in a state of revolt, or nearly or wholly lost to him. Spain was governed by the Dynasty of Umeiyeh, and Africa by that of El-Mahdee; and we have seen the distracted state of Egypt since the fall of the Bence-Tooloon. El-Ikhsheed availed himself of these circumstances to make himself the independent sovereign of Egypt and Syria, continuing, however, to acknowledge the spiritual supremacy of the caliph. Shortly after, he defeated the forces of El-Mahdee, who had again made an inroad into the country, and in 327 he was decorated by Er-Râdee with the title of El-Ikhsheed, a name borne by the rulers of the province of Ferghâneh in Transoxania, from whom he was descended. In the following year Ibn-Râik subdued a great part of Syria, and having taken Damascus advanced to the frontier of Egypt, where after a very severe engagement he was utterly routed and pursued by the troops of El-Ikhsheed as far as Damascus. There, however, the fortune of war turned against El-Ikhsheed, and for a time he was deprived of the province of Syria, though he subsequently regained possession of it. During his reign, the caliphs of Baghdad were daily losing power, and in the year 333, El-Muktefee wrote to him lamenting his miserable state; whereupon El-Ikhsheed immediately repaired to him at Rakkah with valuable presents and offered him assistance and an asylum in Egypt, of which the caliph was too timid to avail himself. About this time, also, he conducted a war with various success against Seyf-ed-Dowleh the Hamdânee, who had attacked Syria. He died at Damascus in 334 (A.D. 946), in the 66th year of his age, and was buried, as were his sons, in the mosque of Omar at Jerusalem.

Of El-Ikhsheed's two sons and successors, Abu-l-Kâsim Oongoor (who died in 349), and Abn-l-Hasan 'Alee, little is known, their vizar Kâfoor, a black eunuch, being the actual ruler. In the reign of the former, in the year 343, a great fire occurred in El-Fustât, which destroyed 1700 houses and much merchandise. Kâfoor succeeded to the throne in 355, and was acknowledged throughout Egypt, Syria, and the Higaz. He ruled with great ability, and was a patron of literature; his name is celebrated by the poet El-Mntanebbe, who was his boon-companion, and whom, as well as other learned men, he rewarded with magnificent presents. On his death in 357, internal dissensions respecting the succession of Abn-l-Fuwârs, a son of 'Alee, presented a favourable opportunity to the Fâtîmee caliph to renew the often-repeated invasions of Egypt.

Hitherto, with few exceptions, the most notable of which are the reigns of Ibn-Tooloon, Khumaraweyh, El-Ikhsheed, and Kâfoor, the Muslim rulers of Egypt had not much benefited the country, or rescued it from the anarchy and troubles in which it had become involved under the Lower Empire. But the incidents of the time are so little known that they have been deemed worthy of more mention in this article than perhaps their importance would otherwise warrant. From the period at which we have now arrived, however, the annals of Egypt contain much important matter, and are so closely interwoven with the events of the Crusades as to render them deeply interesting to the student of European history. The rise of the schismatic caliphs of Africa is a remarkable episode in the early days of El-Islâm, and most of the princes of that dynasty were not unworthy of their successors, the renowned Salâdin and his family, and the Memlook sultans.

In the year 358 (A.D. 969) El-Mo'izz h-deem-llâh, the fourth Fâtîmee caliph, equipped a large and well-armed force, with a formidable body of cavalry, the whole under the command of Abn-l-Hoseyn Gôhar el-Kâid, a native of Greece, and a slave of his father El-Mansoor. This general, on his arrival near Alexandria, received a deputation from the inhabitants of El-Fustât, charged to negotiate a treaty. Their overtures were favourably entertained, and the conquest of the country seemed probable without bloodshed.

But, while the conditions were being ratified, the Ikhsheedees prevailed on the people to revoke their offer, and the ambassadors on their return were themselves compelled to seek safety in flight. Góhar lost no time in pushing forward. Before El-Geezeh a partial combat took place; several days were passed in skirmishes, and at length he forced the passage of the Nile a few miles south of that town, at the head of his troops. Here the Ikhsheedees offered a brave resistance; the greater part were left dead on the field, and the remainder, taking what valuables they could carry off, fled from El-Fustát. The former mediators were now brought to intercede for the inhabitants and the women of the fallen dynasty, and to the honour of the African general it is related that they were pardoned and the city was peaceably occupied. The submission of the rest of Egypt was secured by this victory; and all the Higáz, including the holy cities, and the Yemen, speedily acknowledged the authority of the Fátíme El-Mo'izz. In the year 359 Syria was also added to his dominions, but shortly after was overrun by the Karmatees (Carmathians), the troops of El-Mo'izz met with several reverses, Damascus was taken, and those lawless freebooters, joined by the Ikhsheedees, advanced to 'Eyn-Shems. In the meanwhile, Góhar had fortified El-Káhíreh,¹ or Cairo (the new capital which he had founded immediately north of El-Fustát), and taken every precaution to repel the invaders; a bloody battle was fought on Friday, the 1st of Rabee' el-Owwal, in the year 361, before the city walls, without any decisive result. On the following Sunday, however, Góhar obtained a great victory over the enemy, who experienced a reverse more complete than any before, suffered, and the camp and baggage fell into the hands of the conqueror.

At the earnest solicitations of his lieutenant, who had ruled Egypt both ably and justly, with almost absolute authority, El-Mo'izz at length determined to remove his court to his new kingdom. In Ramadán 362, he entered El-Káhíreh, bringing with him the bodies of his three predecessors and vast treasure. El-Mo'izz reigned about two years in Egypt, dying in the year 365. He is described as a warlike and ambitious prince, but, notwithstanding, he was especially distinguished for justice and was fond of learning. He showed great favour to the Christians, especially to Severus, bishop of El-Áshmoneyn, and the patriarch Ephrem, and under his orders, and with his assistance, the church of the Mu'allakah, in Old Misr, was rebuilt. He executed many useful works, (among others rendering navigable the Tanitic branch of the Nile, which is still called the canal of El-Mo'izz), and occupied himself in embellishing El-Káhíreh. Góhar, when he founded that city built the great mosque named El-Azhar, the university of Egypt, which to this day is crowded with students from all parts of the Muslim world. The principal event of his reign in Egypt was the second irruption of Hasan the Karmatee. The enemy, as on the former occasion, reached 'Eyn-Shems; but now he gained more advantage over the African troops. Although he was twice defeated in different parts of Egypt, and constantly harassed in his advance, the capital was closely besieged by him, and its defenders were driven across the fosse. Thus straitened, El-Mo'izz had recourse to stratagem, and succeeded in bribing Hasan Ibn-El-Garráh (who, with a body of the tribe of Tei, fought with the Karmatees) to desert them in the heat of the next battle. The result of this plan was successful, and again Hasan was defeated and compelled to flee. This event, which occurred in the year 363, relieved Egypt of another invader, an ally of Hasan, by name Abd-Allah Ibn-Obeyd-Allah (formerly governor of Syria under Káfoor), and obtained for the arms of El-Mo'izz various successes in Syria.

El-'Azeez Aboo-Mansoor Nízár, on coming to the throne of his father, immediately despatched an expedition against the Turkish chief El-Eftekeen, who had taken Damascus a short time previously. Góhar again commanded the army, and pressed the siege of that city so vigorously that the enemy called to their aid the Karmatees. Before this united army he retired by little and little to Ascalon, where he prepared to stand a siege; but being reduced to great straits, he purchased his liberty with a large sum of money. On his return from this disastrous campaign, El-'Azeez took the command in person, and meeting the enemy at Ramleh, was victorious after a bloody battle; while El-Eftekeen, being betrayed into his hands, was with Arab magnanimity received with honour and confidence, and ended his days in Egypt in affluence. El-'Azeez followed his father's example of liberality. It is even said that he appointed a Jew his vizir in Syria, and a Christian to the same post in Egypt. These acts, however, nearly cost him his life, and a popular tumult obliged him to disgrace both these officers. After a reign of twenty-one years of great internal prosperity he died (A.H. 386) in a bath at Bilbeys, while preparing an expedition against the Greeks who were ravaging his possessions in Syria.

¹ The modern Cairo was originally called El-Mansooriyyeh; El-Mo'izz, however, changed its name to that of El-Káhíreh, by reason of an omen at its foundation. For details respecting this and the other capitals of Egypt under the Muslims, see the sketch in the *Englishwoman in Egypt*, vol. i. 124, *scgg.* in which the author has availed herself of the valuable MS. notes of Mr. Lane.

El-'Azeez was distinguished for moderation and mildness, but his son and successor rendered himself notorious for very opposite qualities. El-Hákím bi-amr-illáh Abco-'Alee Mansoor began his reign, according to Muslim historians, with much wisdom, but afterwards acquired a character for impiety, cruelty, and unreasoning extravagance, by which he has been rendered odious to posterity. He is described as possessing at once "courage and boldness and cowardice and timorousness, a love for learning and vindictiveness towards the learned, an inclination to righteousness and a disposition to slay the righteous;" and this character is fully borne out by his many extravagances. Of his cruelty numerous anecdotes are told us, especially in the discharge of his functions as Mohtesib, or "regulator of the markets and of the weights and measures," an office which he assumed, and in which he became the terror of the inhabitants. But his cruelty was surpassed by his impiety. He arrogated to himself divinity, and commanded his subjects to rise at the mention of his name in the congregational prayers, an edict which was obeyed even in the holy cities, Mecca and Medinah. He is most famous in connection with the Druses, a sect which he founded and which still holds him in veneration and believes in his future return to the earth. He had made himself obnoxious to all classes of his subjects, when, in the year 397, he nearly lost his throne by foreign invasion. Hishám, surnamed Abco-Rekweb, a descendant of the house of Umeiyeh in Spain, took the province of Barkah with a considerable force and subdued Upper Egypt. The caliph, aware of his danger, immediately collected his troops from every quarter of the kingdom, and marched against the invader, whom, after severe fighting, he defeated and put to flight. Hishám himself was taken prisoner, paraded in Cairo with every aggravation of cruelty, and put to death. El-Hákím having thus by vigorous measures averted this danger, Egypt continued to groan under his tyranny until the year 411, when he fell by domestic treachery. His sister Seyyidet-el-Mulook had, in common with the rest of his subjects, incurred his displeasure, and being fearful for her life, she secretly and by night concerted measures with the emeer Seyf-ed-Dowleh, chief of the guard, who very readily agreed to her plans. Ten slaves, bribed by 500 deenárs each, having received their instructions, went forth on the appointed day to the desert tract southward of Cairo, where El-Hákím, unattended, was in the habit of riding, and waylaid him near the village of Hulwán, where they put him to death.

He was succeeded by his son, Edh-Dhábir (commonly pronounced Ez-Záhir) bi-lláh Abu-l-Hasan 'Alee, who ruled with justice and moderation for nearly sixteen years. In 414 Aleppo was taken by Sálíh Ibn-Mardás, and although he was defeated and slain by an Egyptian force sent against him, a son, Shibl-ed-Dowleh, yet retained possession of that city. At this time also Hasan, of the tribe of Tei, before mentioned, had made himself master of Ramleh; and indeed from this caliph's reign we may date the decline of the Fátíme power, especially in Syria.

In the year 427, El-Mustansir bi-lláh Abco-Tameem Ma'add came to the throne at the age of seven years. His reign occupied a long period, rendered remarkable by the unparalleled troubles which befell Egypt. It commenced prosperously with the defeat and death of Shibl-ed-Dowleh. Aleppo was taken, and the submission of the rest of Syria followed; and the general who had conducted the expedition against that province assumed its government. On his death, Mo'izz-ed-Dowleh, a brother of Shibl-ed-Dowleh, retook Aleppo in 433, but the various fortunes of this prince and his nephew Mahmood, from this time and during the calamities of Egypt, are too complicated and subordinate to claim a place here. In the western provinces, the rebel El-Mo'izz (the third successor of Yoosuf Ibn-Zeyree, who was appointed governor on the conquest of Egypt), was punished by an irruption of wild Arab tribes in the pay of El-Mustansir.

In the year 450 (A.D. 1058), the Fátíme caliph was publicly prayed for in Baghdád,—a remarkable event, of which the immediate cause was briefly as follows. El-Besásceeree, a powerful Turkish chief exercising unbounded authority in that city, had fallen into disgrace, and received supplies of men and money from the caliph of Egypt; and while the Selhooke sultan Tughril-Beg espoused the cause of the 'Abbásce caliph, his brother Ibraheem Eynál revolted, joined El-Besásceeree, and defeated Tughril-Beg. El-Besásceeree entered Baghdád, in which the combat continued to rage; and the unfortunate city was devastated by massacre and pillage. El-Mustansir was solemnly declared Prince of the Faithful, and the insignia of the legitimate caliph was sent to El-Káhíreh. The success of El-Besásceeree, however, was but transient; Tughril-Beg had, in the meantime, defeated and killed his brother Ibraheem; he then entered Baghdád in Dhul-Kadál 451, and despatched a force against El-Besásceeree, who fell in a battle near El-Koofeh.

A persecution of the Christians of Alexandria occurred about this time; and in 454 commenced a desolating struggle between the blacks and the Turks, both of whom had become numerous in Egypt. The former were succoured by the mother of El-Mustansir,

herself a negro, while the command of the latter was taken by Nasir-ed-Dowleh Ibn-Hamdan, a general of El-Mustansir, more than once governor of Damascus, and at this period governor of Lower Egypt. To this man's unscrupulous ambition was due much of the trouble which ensued. After many battles the Turks succeeded in destroying the power of their adversaries, and their leader assumed almost absolute authority, while they not only extorted from the caliph immense sums of money and treasure, but even rifled the tombs of his predecessors for the valuables which they contained. At the same time the bulk of the valuable library of the Fátimées was dispersed by these brigands. But the very power of Nasir-ed-Dowleh threatened his overthrow. His sense of security in his position rendered him regardless of the support of the Turks; and when at length his schemes for the deposition of El-Mustansir brought matters to a crisis, a large portion of the army declared against him. Defeated and driven from the metropolis, he succeeded in possessing himself of Lower Egypt, and a terrible civil war raged between the contending parties. But an even heavier calamity afflicted Egypt. For seven successive years the inundation of the Nile failed, and with it almost the entire subsistence of the country, while the rebels intercepted supplies of grain from the north. El-Makreezi informs us that El-'Askar and El-Kata' were depopulated, and that half the inhabitants of El-Fostat perished, while in El-Káhreh itself the people were reduced to the direst straits. Bread was sold for 14 dirhems the 1 lb loaf, and all provision being exhausted, the worst horrors of famine followed. The wretched people resorted to cannibalism, and organized bands kidnapped the unwary passenger in the desolate streets by means of ropes furnished with hooks and let down from the latticed windows. In the year 462 the famine reached its height. It was followed by a pestilence; and in the midst of these horrors, Nasir-ed-Dowleh advanced on El-Káhreh at the head of an enormous army; he was induced to withdraw by the promise of large concessions, only to repeat the attack, and finally to make himself master of the city, after having inflicted a signal defeat on the caliph, who became only the nominal ruler of Egypt, a condition which lasted until the assassination of this powerful rebel in the year 465.

While these events were occurring in Egypt, Syria was in a continual state of anarchy and war. A distinguished general, the emir El-Guyoosh Badr-ed-Deen El-Gemálee, held the government of Damascus during these times, and now El-Mustansir wrote, recalling him to assume the office of vizir of Egypt. On the condition of being allowed to bring with him a veteran force, he, happily for the country, obeyed the summons, and to his talents was owing the restoration of order and even prosperity which followed. By a massacre of emirs at a grand banquet shortly after his arrival, and by numerous executions, he subdued all opposition in the capital, and in a series of brilliant victories he annihilated the savage hordes who infested the country throughout its whole extent, having either been called to the aid of the contending parties, or voluntarily taken advantage of the universal confusion to commit their lawless ravages.

In concluding this necessarily extended notice of the reign of El-Mustansir, the invasion of Aksees with an army of Turkomans, Kurds, and Arabs, in the year 469, must be mentioned. Spreading devastation around them, they encamped near El-Káhreh, and in the first engagement defeated the forces of El-Gemálee, but fortune favouring him in a second battle, the enemy was totally routed with immense carnage.

El-Mustansir reigned 60 years, and died in the year 467. He was a weak prince, solely given up to pleasure. El-Gemálee had governed with almost absolute authority and great ability for a period of 29 years, dying only a few days before the caliph. While admiring El-Gemálee's talents, we cannot but condemn his avarice. He built the mosque which gives its name to the mountain immediately S. E. of the citadel of El-Káhreh (Gebel-El-Guyoosh), and the second wall of the city, with its three principal gates, Bab-Zeyzeleh, Bab-en-Nasr, and Bab-el-Futooh. These gates, which are very fine specimens of architecture, are said to be the work of three Greek brothers.

El-Mustansir's son, El-Fázil Abn-el-Kásim Ahmad succeeded his father; but as son of El-Gemálee, El-Afdal, had the principal management of the affairs of the kingdom. This caliph's reign is memorable for the first Crusade. El-Afdal had taken Jerusalem from the Turks in the year 491 (A. D. 1098); and a few months later it yielded to the Crusaders, after a siege of 40 days. El-Afdal arrived at the city after its fall with a reinforcement of 20,000 men, but he was defeated in the battle of Ascalon. Later, an Egyptian army, commanded by Saad-el-Dowleh, was worsted by Baldwin, count of Flanders, and the general was killed in the action. From this period, with the exception of some efforts made in the next reign, to the time of Saláhdin ("Saladin"), Egypt was too much engaged with internal troubles to equip expeditions against the west, except as when it struggled for the possession of Syria. El-Mustansir died in the year 495. He is stated to have been a Shi'ite, a strange anomaly in a dynasty of Shi'ite.

His son El-A'mir bi-ahkám-lááh Aboo-'Alee Mansoor came to the throne at the age of five years, and until his arrival at manhood the government was conducted by El-Afdal. The first act of the caliph, however, on taking it into his own hands, was to put his minister to death, and appoint in his stead a man whose wickedness obliged him to imprison him and afterwards condemn him to death. The rule of El-A'mir was chiefly remarkable for his impiety and tyranny, and for the successes of the Crusaders, who, having reduced many of the principal coast-towns in Syria, meditated the conquest of Egypt, and crossed the frontier, but were deterred from the prosecution of their enterprise by the illness of Baldwin, whose death took place at El-Areesh, on his way back to Jerusalem. El-A'mir was put to death in 524, at the town of El-Geezeh, it is said by partisans of El-Afdal, whose son then usurped the entire government, setting up, as caliph, El-Háfídh h-deeni-lááh Abd-El-Megeed, a grandson of El-Mustansir (El-Anur having left no male issue), but without the usual ceremonies of installation. This vizir, Aboo-Alee Ahmad, even forbade the mention of El-Háfídh in the public prayers, and inserted his own name in his stead. He perished in a popular tumult, roused by his extortions and arbitrary rule, and El-Háfídh was duly declared caliph and received the oaths of allegiance. After the death of Ahmad, he successively appointed three other vizirs; but these proving equally refractory, he at length dispensed with that office altogether. He reigned nearly 20 years. The licentiousness of his son and successor, Edh-Dháfir bi-aadái-lááh Aboo-Mansoor Isma'eel, occasioned his death in four years and seven months at the hand of his vizir El-'Abbás.

El-Fázil bi-lááh Abn-el-Kásim 'Eesa Ibn-'Alee was, on his accession in 549, only five years of age, and the history of his times presents merely the contentions of rival vizirs, of whom the chief were El-Melik Es-Sálih Tatáe Ibn-Ruzzeyk, and his competitor El-'Abbás, before named. The latter, finding his power failing, gathered together the wealth he had amassed and fled to Syria, where he fell into the hands of the Crusaders, who stripped him of all that he had and detained him a prisoner. Eventually he was given up to Tatáe and crucified over the gates of the palace.

El-Fázil died in the year 555, and El-'Adil h-deeni-lááh Aboo-Mohammad Abd-Allah, a grandson of El-Háfídh, and the last of the Fátimée caliphs, was raised to what was then but the shadow of a throne, the entire power being in the hands of Tatáe, who by his oppression and cruelty well-nigh rendered El-'Adil, by nature benevolent and wise, as tyrannical as himself. He was assassinated after a year by the secret orders of the caliph, and the latter to conceal his agency in this act installed his son El-'Adil in his place. At this time the well-known Sháwír was governor of the Sa'ced (or Upper Egypt), a post next in importance to that of prime minister. During the last three reigns the vizirs had been rapidly increasing in power, and the annals of the period are entirely occupied with the rise and fall of potent grandees, all eager for a post which conferred on its possessor the supreme authority. At length, in the reign of this unfortunate prince, they consummated the ruin of the dynasty and overwhelmed themselves in its fall. In 558 El-'Adil dispossessed Sháwír of his government, and the latter had immediate recourse to arms, marched against his enemy, and succeeded in putting him to death. He then constituted himself vizir, but in his turn was compelled to flee from a more powerful rival, Ed-Dirghám Noor-ed-Deen (Nonreddin), the sultan of Damascus, received the fugitive with favour; and in the course of the next year (559) despatched an army to Egypt, under the command of Asad-ed-Deen Sheerkooch, to reinstate him. In the meantime Ed-Dirghám had been busy putting to death the great men of the empire, and having thus weakened his power, he offered but a feeble resistance, was overthrown in a battle near the tomb of the Seyyideh Nefeesch, on the S. of El-Káhreh, and Sháwír was restored. No sooner, however, was this effected, than he forgot the engagements into which he had entered with Nouredin, and threw off his allegiance to him. Sheerkooch retired to the Sharkeeyeh, and occupied the town of Bilbeys, and thence threatened Sháwír. In this position of affairs the latter had recourse to the Crusaders, who willingly responded to his call, and Ananry, king of Jerusalem, arrived with a considerable force. With these allies, Sháwír besieged his former protector in Bilbeys, until, hearing of Nouredin's successes over the Franks in Syria, they negotiated a peace, and permitted Sheerkooch to withdraw from Egypt. About two years later, Nouredin, determined on punishing the treachery of Sháwír, again sent Sheerkooch into Egypt with a great army, and accompanied by his nephew, the famous Saládhin. Sháwír again sought to strengthen himself by an alliance with Amaury, from whom he received the first intelligence of the meditated invasion. Apprised of this knowledge of his movements, Sheerkooch changed his course from Bilbeys, entered the valley of the Nile at some distance above Cairo, and crossing the river marched northwards to El-Geezeh. Here he endeavoured to raise the people against Sháwír and his Frank confederates; and had in some measure succeeded when the superior forces of the enemy

compelled him to retreat southwards as far as El-Bábeyn, near Ashmooneyn, where he risked an engagement, and gained a complete victory. This success opened to the invaders the greater part of Egypt, and Alexandria itself fell into their hands. Saladin was placed in that city with a numerous garrison, and his uncle departed to subdue the rest of Egypt. The Crusaders, however, at once closely invested Alexandria, and so pressed the siege for three months, as to oblige Sheerkooli to come to its relief. An honourable compromise was effected, by which the Syrians agreed to resign their conquests and evacuate Egypt. But fresh troubles were in store for this unfortunate country. Amaury, irritated at the result of a campaign in which he had only lost, determined on an expedition against his recent ally, and, entering Egypt, took Bilbeys, putting its inhabitants to the sword, and laid siege to El-Kalureh, his course being marked by the most dreadful barbarities. On his approach, the ancient city of El-Fustát was set on fire by order of the vizir, to prevent it falling into the enemy's hands, and it continued burning somewhat more than fifty days. El-'Adid now earnestly sought the aid of Noureddin; and that monarch, actuated by religious zeal against the Franks, who had already felt his power in Syria, and by the desire of conquest, once more despatched Sheerkooli. In the meantime negotiations had been opened with Amaury to raise the siege of El-Kalureh, on payment of an enormous sum of money; while, however, the conditions were yet unfulfilled, the approach of the Syrian army induced him to retreat in all haste. Sheerkooli and Saladin entered the capital in great state, were received with honour by the caliph and with obsequiousness by the peridious Sháwir, who was contriving a plot which was fortunately discovered and for which he paid with his head. Sheerkooli was then appointed vizir by El-'Adid, but dying very shortly, he was succeeded in that dignity by Saladin 564 (A.D. 1169).

For the short period which elapsed before Saladin's assumption of the title of sultan a few words will suffice. One of his first acts was to put to death the chief of the eunuchs, and a revolt of the blacks resulted; a combat took place in El-Káhireh in the street called Beyn-el-Kasreyn; and the malcontents being worsted, the disturbances were quelled. Babá-ed-Deen Karikooshi, a white eunuch, who afterwards played a prominent part in the reign of Saladin, was appointed to the vacant post. This gave the vizir great influence in the palace, of which he judiciously availed himself. In 565 we hear of Amaury with Greek allies unsuccessfully besieging Damietta; and in the following year, Saladin conducted an expedition against the Franks to Ascalon and Ramleh. In 567, by order of Noureddin, he suppressed the name of El-'Adid in the congregational prayers, and substituted that of the 'Abbásee caliph, a masterly stroke of policy to secure the adhesion of the orthodox Muslims. The last of the Fátimées was lying dangerously ill, and his relations concealed from him his degradation. He died without the knowledge of it, and with him perished an illustrious but unfortunate dynasty.

Saladin was thus relieved of the most serious obstacle on his way to the throne; yet he dared not throw off his allegiance to the sultan of Damascus, but prudently waited for a favourable opportunity. Noureddin's suspicion was already aroused, and he died (in 569) while secretly preparing to proceed in person to Egypt. Saladin almost immediately proclaimed himself sultan of Egypt, and inaugurated his reign with a series of brilliant successes. With the conquest of El-Mo'izz, Egypt again took an important place among the nations; and by the wars of Saladin it became the nucleus of a great empire. But military glory was not the sole aim of this prince and his successors. The patronage they continued to extend to letters and the arts had the most beneficial effect upon the civilization of the country.

Saladin, whose full appellation was El-Melik En-Násir Salih-ed-deen Yoosuf Ibn-Eiyoub, acquired his greatest renown by his campaigns against the Crusaders in Syria. As these belong, however, more properly to the history of those wars than to that of Egypt, they will be more briefly noticed in this place than would otherwise be necessary. The youth of El-Melik Es-Sálih Isma'eel, the son and successor of Noureddin, and the consequent confusion which prevailed in his dominions, gave Saladin a fair pretext to occupy Damascus, as the guardian of the young prince, and enabled him to wrest from him his kingdom. He thus considerably enlarged his territory, made himself master of a great portion of Syria, and continued to consolidate his power in those parts until the year 572 (A.D. 1178), when

Philip, count of Flanders, laid siege to Antioch, and Saladin entered Palestine. Having encamped before Ascalon, the Egyptian troops ravaged the neighbouring country, and set fire to Joppa, until at length Baldwin the Leper, king of Jerusalem, issued from Ascalon and gave them battle. The result was disastrous to Saladin: his army was totally routed, and he himself fled alone on a dromedary. After this, however, he gained some partial advantages over the Christians, till a terrible famine induced him two years later to conclude a truce with the king of Jerusalem and to retire to Egypt.

In the year 576 he again entered Syria and made war on Kilij-Arslán, the Seljooke Sultan of Anatolia, and on Leon, king of Armenia, the Cilicio-Armenian kingdom, both of whom he forced to make terms of peace. Not long after his return, Saladin departed from Egypt (A.H. 578) to prosecute a war with the Crusaders in which neither side desired peace. Their hostility was aggravated by the following circumstances. A vessel bearing 1500 pilgrims had been wrecked near Damietta, and its passengers captured; and to the remonstrances of the king of Jerusalem the sultan replied by complaining of the constant inroads made by Renaud de Châtillon. At this time the latter turbulent chief undertook an expedition against Eyleh, and for this purpose constructed boats at Karak and conveyed them on camels to the sea; but this flotilla was repulsed, and the siege raised by a fleet sent thither by El-'Adil ("Saphedin"), the brother of Saladin, and then his viceroy; and a second attempt was still more unfortunate, the Christian captives on that occasion were sacrificed in the valley of Minna. Having threatened Karak, Saladin encamped at Tiberias, and ravaged the territory of the Franks; he then besieged Beyroot, but in vain; and thence turned his arms against Mesopotamia and subdued the country, but the city of Mosul successfully resisted him. In the meanwhile, the Crusaders contented themselves with miserable forays across the enemy's borders, and made no serious preparations for the return of their redoubtable antagonist. The latter, having been almost everywhere successful in Mesopotamia, took Tell-Khálid and 'Eyn-Tab in Syria and obtained possession of Aleppo; he again besieged Karak, ravaged the territory of Samarra, and later received the fealty of the lord of Mosul, but not the keys of the city.

In the year 582 (1186 of our era) war again broke out between Saladin and the Crusaders. The sultan had respected a truce into which he had entered with Baldwin the Leper, and Renaud, before named, was the first to break it. The capture by the latter of a rich caravan enraged Saladin, who despatched orders to all his lieutenants and vassals, summoning them to assist in the "Holy War." He marched (A.D. 1187) from Damascus to Karak, and there laid close siege to Renaud; at the same time a large body of cavalry under the command of his son, El-Afdal, advanced on Nazareth; and here a body of 130 Knights Hospitallers and Templars, seconded by a few hundred foot soldiers, and encouraged by the heroic Jacques de Moillé, marshal of the Temple, by their devotion immortalized their memory. Only the Grand Master of the Temple and two of his knights escaped from the unequal struggle. Soon after, Saladin approached in person at the head of an army of 80,000 men; and the Christians with their whole force encountered him on the shore of the Lake of Tiberias. The result of the battle which ensued was the heaviest blow which had yet fallen on the Crusaders. Weakened by thirst, shaken by the flight of a part of their troops on the second day of combat, and overwhelmed by numbers, the knights fought with desperate courage, but at length were forced to the hills of Hitteem. A multitude fell in this bloody fight, and among the prisoners were Guy

de Lusignan (the king of Jerusalem and successor of Baldwin), with his brother and Renaud de Châtillon. The number of prisoners is almost incredible; and the massacre of many of them is an indelible stain on the glory of the generally merciful Saladin. Tiberias, Ptolemais (Acre), Nablus, Jericho, Ramleh, Cesarea, Arsour, Joppa, Beyroot, and many other places successively fell into the hands of the conqueror. Tyre resisted his attacks; but Ascalon surrendered on favourable terms, and the fall of Jerusalem crowned these victories. The great clemency of Saladin on this occasion is chronicled by Christian historians, though it is but slightly mentioned by the Muslims, who took offence at the mercy shown to the enemies of their faith.

After these events Tyre was again besieged, and when about to capitulate was relieved by the arrival of Conrad, son of the marquis of Montferrat. The valiant defence of the town worried Saladin, who turned his arms against Tripoli, but here he met with no better success. Bohemond, prince of Antioch, and at that time possessor of Tripoli also, was, however, glad to obtain a truce of eight months, and some strongholds (among others Karak) were taken. But now the fortune of war turned against the sultan. The ever-memorable siege of Acre, maintained with equal constancy by both Christians and Muslims, lasted upwards of two years, and attracted the attention of the whole western world. At length the immense reinforcements received by the besiegers, and the presence of Richard Cœur de Lion of England and of Philip II. of France, enabled them to overcome all resistance, and the standards of the Cross floated on the ramparts of the city (A.D. 1191). A horrible net of barbarity was here perpetrated: 2700 Muslim captives were massacred in cold blood, in consequence of Saladin's having failed to fulfil the terms of the capitulation; and the palliative plea of the heat of an assault cannot be urged in extenuation of this enormity. Richard has been accused of being its author; but Michaud believes with reason that it was decided on in a council of the chiefs of the Crusade. On another occasion, however, that king was certainly guilty of similar cruelty.

After a period of repose and debauchery, the army of the Crusaders, commanded by Richard, directed its march towards Jerusalem. Saladin harassed his advance on every point, rendered the cities and strongholds defenceless, and ravaged the country. Richard, nevertheless, was ever victorious, his personal bravery struck terror into the Muslims, and he gained a signal victory over the sultan in the battle of Arsour. But dissensions among the chiefs of his army and the uncertain temper of the commander himself deterred the Crusaders from the attainment of their great object, the deliverance of the Holy City; and when all the coast from Joppa to Tyre was in the hands of the Christians, and the army of Saladin was threatened with disorganization, a treaty was concluded, and Richard set sail on his return to England. The glory acquired by Saladin, and the famous campaigns of Cœur de Lion, have rendered the Third Crusade the most memorable in history, and shed a lustre on the arms of both Muslims and Christians greater than they ever attained in those wars, either before or afterwards.

Saladin died about a year after the conclusion of this peace (A.D. 1193 or 1193 of our Era) at Damascus, at the age of fifty-seven years. Ambition and religious zeal appear to have been his ruling passions; he was courageous, magnanimous, and merciful, possessed of remarkable military talents and great control over himself. His generosity to the vanquished and his faithful observance of his sacred word are lauded by the historians of the Crusades; the former brought on him much obloquy from his own forces, and is a trait in his character which is mostly of note in the annals of a time when this

virtue was extremely rare. While engaged in the conduct of his continual wars, he was not unmindful of the welfare of Egypt, and during his reign many public works were executed. Of these we may mention especially the citadel of Cairo, with the magnificent buildings which, until very recently, it contained; the third wall of the city; and the repair of the great canal called the Bahr Yoosuf, a very important and useful work. From the year 578 until the period of his death he had not entered Egypt; but his brother El-Melik El-'Adil Seyf-ed-deen (Saphedin) and other princes of his family successively governed that country, and the eunuch Karakoosh, who also defended Acre, held a large share of authority.

On the death of Saladin, his extensive dominions were divided chiefly among his sons, and Egypt fell to the lot of one of them, El-Melik El-'Azeez Imad-ed-Deen 'Othman. The grandees supported his claim to the throne, and he proved himself worthy of their choice. In conjunction with El-'Adil, we find him warring against the leaders of the Fourth Crusade. He reigned nearly six years, and was succeeded (in 595) by his son El-Mansoor Mohammad, whose uncle El-'Adil was compelled to relinquish the government of Damascus and assume the regency of Egypt. Disagreement among the sons of Saladin had occurred soon after that monarch's death, and now hastened the rise of El-'Adil, who, by his military talents and other remarkable qualities, had excited the fears of even his brother. With the view of checking his growing ascendancy, El-'Adil formed an alliance against him with Edhi-Dhahir, another son of Saladin and lord of Aleppo, and besieged him in Damascus; but coming to strife, they raised the siege in 597. This attempt proved fatal to the power of El-'Adil. He was pursued to Egypt, in his turn besieged in El-Kähireh, and forced to flee, and El-'Adil was proclaimed sultan. Having dethroned El-Mansoor, he speedily recovered Damascus from the hands of the confederate brothers, and Syria with Egypt acknowledged his supremacy. El-'Adil (as Saphedin) is especially known by his opposition to the Fourth and Sixth Crusades, the former of which took place before his accession to the throne. He repulsed the Christians near Nablus, captured Joppa, and encountered the enemy between Tyre and Sidon. He was there defeated with heavy loss, and Sidon, Laodicea, Gibleh, and Beyroot were taken. But the Crusaders wasted their strength before the fortress of Thoron. El-'Adil raised the siege of that place, and although afterwards he met with a reverse near Joppa, his adversaries bought a dear victory; and, having come to terms of peace, they returned to Europe. In the year 600 (A.D. 1204) he departed to Syria with the object of securing Jerusalem against threatened attacks, and concluded a truce which he offered to renew when about to expire; and to prove his good faith, he strengthened that offer by promising to cede ten castles to the Christians. These overtures were refused, and the Muslim army drove the newly arrived king of Jerusalem, Jean de Brienne, back to Europe. Those who remained then professed their willingness to accede to conditions of peace, and we do not again hear of El-'Adil in Palestine until 614 (A.D. 1217), when he was once more called thither to oppose the Crusaders; but a serious invasion of Egypt by these troublesome adventurers hastily recalled his king, and he died of grief, it is said, on hearing of the advantages gained by them.

El-Kamil immediately (615) came to the throne, and took the most energetic measures for the protection of his kingdom. In the meantime, the Franks had besieged Damietta both by sea and land, and, notwithstanding every effort for the relief of the place, its garrison was forced to capitulate. El-Kamil summoned to his aid the princes of his family, and with every available man watched the enemy's movements. Flushed with success, Jean de Brienne commenced his march on the capital; and with the characteristic carelessness of the Crusaders he took no measures to secure supplies. His advance was stopped at the junction of the canal of Ashmoon with the Nile, where he found El-Kamil in a very strong position. Encamped on the opposite shore, the invaders depended for supplies on Damietta and its immediate district; but the inundation of the Nile gradually obstructed land-carriage, and El-Kamil, skilfully availing himself of this natural ally, caused boats to be carried overland to the enemy's rear, and, thus cut off by land and water, they were compelled to attempt a retreat. At Beyrmoon, however, all further progress was found to be impossible, the inundation had covered the level country, and the sultan's boats blockaded the Nile. The Franks surrendered, and evacuated Damietta, but not before Egypt had suffered severely from the ravages they committed. The town of El-Mansoorah was founded on the site of El-Kamil's camp, and commemorates his energy and sagacity. The Seventh Crusade was invited by the same sultan who had thus suffered by an invasion of the Franks. In A.D. 1228, El-Kamil invoked the aid of Frederick II. against his brother El-Moadhdham, lord of

Damascus, and, in consequence of this alliance, Jerusalem, with Bethlehem and the places between it and Joppa and Acre, Nazareth and the territory of Thoron and Sidon, with its dependencies, was ceded to Frederick on the 20th of Feb 1229. Between these two monarchs existed the most friendly relations, presenting a curious spectacle in the midst of the intrigues and hatred of their subjects for each other, and endangering their popularity and even their lives. After various expeditions against his brother and his successors, El-Kâmil gained possession of Damascus, and died there in the year 635 (A.D. 1238). He was distinguished by military talents and rare moderation, and was also a learned man, a patron of the arts, and a good king.

His son, El-Melik El-'Adil the Younger, was declared sultan of Egypt and Syria, with the consent of the nobles, and he speedily banished those ministers whose counsels he feared, and appointed creatures of his own. Oppressed by his tyranny, and impoverished by his extravagance, the people called his brother Es-Sâlih Negmed-Deen Eiyoub to the throne; and he deposed and imprisoned El-'Adil in the year 637, and to replenish his exhausted treasury, ordered all who had received presents from the late sultan to restore them to his successor. In the next year serious disturbances broke out in Syria, 'Imâd-ed-Deen, who had taken Damascus in the reign of El-'Adil, formed an alliance with the Franks, and purposed the conquest of Egypt, the hostile armies met at Acre, and the Muslim soldiers of 'Imâd-ed-Deen deserting to the banner of Es-Sâlih Eiyoub, the Franks were routed. Negotiations for peace were then attempted, but these failing, the Franks were again induced to take the field by the cession of Jerusalem and other places. The king of Egypt, on his part, called to his assistance the Tatars of Khâresm, who took Jerusalem and overran Syria. In the next campaign (642) they were joined by the army of Es-Sâlih, under the command of his favourite slave Beybars, or Eibars, who was destined to play a conspicuous part in Egyptian history. At Gaza the allied army met the Franks, eager to avenge themselves on the Khâresmees for the horrible atrocities of which they had been guilty in the preceding campaign, and willingly joined by the Muslim princes of Damascus, Hims, and Karak; on the first day the battle raged with unabated fury from daybreak to sunset, and was continued on the morrow until the prince of Hims, having lost 2000 men, gave way and fled towards Damascus. The Christians maintained the unequal fight with great constancy, and were only vanquished after the greater number had fallen. In these encounters 30,000 men (Christians and Muslims) were either killed or taken prisoners. Various successes followed this victory, Jerusalem was taken by the Egyptians, and Es-Sâlih laid siege to Damascus in person. The city having capitulated on favourable conditions, his fierce allies, enraged at the loss of pillage, quarrelled with him, and soon after joined his rebellious subjects. Damascus was reduced to the direst straits, but again fortune favoured Es-Sâlih. He hastened from Egypt, whither he had returned, and totally defeated the enemy. Other advantages were gained by his commander Fakhr-ed-Deen over the Franks in 645.

Although attacked by illness, the sultan was once more called to Syria to quell fresh troubles; but at Damascus news reached him of the threatened invasion of Egypt by the Crusaders under St Louis, and he travelled back in great suffering from his malady. Damietta, which he rightly judged would be the first point of attack, was strengthened and well stored, and its defence was intrusted to Fakhr-ed-Deen. On Friday, June 4, A.D. 1249, the French anchored before the place, and the next day landed opposite the camp of the Egyptian general, who offered but slight opposition, and in the course of the next night betrayed his trust and retreated southwards. His army was precipitately followed by the entire population of Damietta, and this important town with its stores fell into the hands of the invaders without a blow. Fakhr-ed-Deen nearly lost his life for this act of cowardice, and fifty-four of his principal officers were put to death. In the meantime the sultan's illness gradually increased, but nevertheless he caused himself to be removed to the town of El-Mansoorah, which he fortified, and there he expired on Nov. 21, at the age of forty-four, and after a reign of ten years. He it was who introduced the Bahree Memlooks, a body of Turkish slaves, who composed his body-guard, and eventually usurped the supreme power. Their name *Bahree* (or "of the river") originated in their being trained and quartered on the island of Er-Rôdah, where the sultan had built a palace.

The French were advancing southwards, and, notwithstanding the precautions of Sheger-ed-Durr (the widow of Es-Sâlih, who assumed the regency), were apprised of the death of the sultan. Many partial actions took place on the march, and on Dec. 19, their army appeared before El-Mansoorah, the scene of the disaster of Jean de Brienne. Skirmishing continued until Shrove Tuesday, when, a traitor having shown the enemy a ford over the canal of Ashmoon, they surprised the camp and town. Very severe fighting ensued, Fakhr-ed-Deen fell early in the struggle, and the place was nearly lost, when the Bahree Memlooks led by Beybars furiously charged the assailants, and completely turned the fortune of the day. The morrow witnessed another battle, also disastrous to the

Crusaders, and a succession of misfortunes followed. Tooran-Shâh, on hearing of the death of his father, travelled in all haste from Mesopotamia to Egypt, and having reached the camp assumed the command. He had recourse to the stratagem which had proved so successful under the direction of El-Kâmil, and cut off the supplies of the enemy. This, coupled with disease, soon reduced St Louis to great straits, and he sent to propose a truce, but not coming to terms he resolved on retreating to Damietta. A memorable conflict took place by land and water, and St Louis with his troops surrendered themselves prisoners of war.

Tooran-Shâh now gave himself up to debauchery, offended his nobles by bestowing his favours only on certain creatures whom he had brought with him from Mesopotamia, and alarmed the queen by forcing her to render him an account of his father's wealth. Sheger-ed-Durr appealed to the Memlooks, a conspiracy was formed, and the sultan was attacked in his palace. He fled to a pleasure-tower built on the banks of the Nile, which was set on fire in the presence of his army, the wretched king, from the summit, in vain promising to abdicate. He perished miserably, and his corpse lay unburied for many days on the bank. On his accession he had strangled a brother, and his fate deserves no pity.

Sheger-ed-Durr (vulgarly called Shegeret-ed-Durr), herself a slave, and the first of the Dynasty of the Bahree, or Turkish Memlooks, succeeded to the throne, and 'Izz-ed-Deen Eybek was appointed commander of the forces. After many delays, St Louis agreed to pay 400,000 livres as a ransom for himself and his army, 200,000 to be paid in Egypt, and the remainder on the fulfilment of certain stipulations at Acre. Damietta was surrendered and Egypt evacuated. Thus ended the last invasion of Egypt by the Crusaders. Sheger-ed-Durr, in order to strengthen herself on the throne, shortly after married the emeer Eybek, and caused him to be proclaimed sultan, with the title of El-Melik El-Mo'izz, in the year 648. The followers of the late Es-Sâlih, however, obliged Eybek to associate with himself in the sovereignty a young prince of the family of Eiyoub, El-Melik El-Ashraf Muddaffar-ed-Deen Moosâ. En-Nâsir, a son of El-'Azeer, invaded Egypt, and after many combats was driven back to Syria, but the country continued in a very unsettled state. The chief of the adherents of the fallen dynasty was arrested by Eybek, and Beybars and other leading men having repaired to the citadel to demand satisfaction, his bloody head was thrown to them from the ramparts, and in terror they fled to Syria. El-Ashraf was then cast into prison, and there he died. But Eybek soon roused the jealousy of his beautiful and ambitious wife, and he was assassinated by her orders (655, A.D. 1257). In her turn she was beaten to death, not many days after, by the wooden clogs of the female slaves of another wife of Eybek, and her corpse was exposed for three days in the moat of the citadel.

El-Melik El-Mansoor Noor-ed-Deen 'Alce, son of Eybek, was now raised to the throne, and Beybars being apprised of the death of his rival attempted to regain his power in Egypt; but Kutiz, the viceroy of Eybek and also of his son, attacked and routed him, and he soon after (657) deposed El-Mansoor, and declared himself sultan. El-Melik El-Muddaffar Kutiz began his reign by putting to death El-Mansoor and Sharaf-ed-Deen, the able minister of the last Eiyoobee kings and of the first of this dynasty. A reign thus cruelly commenced ended tragically. Kutiz was diverted from these severe measures by the advance of Hoolagoo, grandson of Genghis-Khân, who, with a formidable army, overran El-'Irâk and Syria. By great efforts Kutiz raised a considerable force and marched to meet him. The intelligence of the death of the Moghul emperor had, however, in the meantime recalled Hoolagoo, who left Ketbooghâ to encounter the Egyptian sultan. The battle declared in favour of the latter, and Syria was restored to his rule. Returning in triumph to Egypt, he was assassinated on the frontier by Beybars in the year 658, and thus Memlook (who had but recently fought under his banner against the Tatars) was forthwith chosen by the emeers to be his successor.

The brilliant reign of El-Melik Edhi-Dhâhir Beybars El-Bundukdâree is so perplexed and full of incident as to render a concise account of it very difficult. It began with the reduction of a revolt in Syria. The rebels were supported by a Tatar army under Hoolagoo, but Beybars was everywhere victorious, and Damascus surrendered at discretion. Having subdued all opposition in this quarter, he endeavoured to improve the condition of Egypt, abolished the exorbitant imposts under which the people groaned, and welcomed to the court Ahmad, son of the caliph Edhi-Dhâhir, who was declared Prince of the Faithful with the title of El-Mustansir bi-Ilâh, and furnished with a small force, by which he hoped to establish himself in Baghdad. He was, however, repulsed by the Tatars and put to death. The succeeding line of caliphs, by the Tatars and put to death. The succeeding line of caliphs, possessed of spiritual, but no temporal authority, remained at the court of the Memlook sultans until the Turkish conquest. From this time, Beybars continued to extend and confirm his rule. His first expedition was to Syria against the Christians, and the Church of the Nativity at Nazareth was destroyed. Thence he went to the fortified town of Karak, which had more than once resisted the attacks of Saladin, but opened its gates to the Memlook conqueror,

and its territory was added to his dominions. A great scarcity afflicted Cairo in 662, and Beybars threw open the Government stores, and strove in every way to alleviate the sufferings of his subjects.

In 663 he again entered Syria, and took Casarea and Ursoof; and in the next year he commenced a series of campaigns against the Christians, notwithstanding the earnest remonstrances of the kings of France, of Aragon, and of Armenia. To raise the necessary funds for the expenses of the war, he took occasion from the occurrence of many incendiary fires in Cairo, during his absence, to mulct their co-religionists of the sum of 500,000 *deenârs*, ostensibly to repair the damage caused by these fires. He threatened Acre, and took Safad, and relieved from the apprehensions caused by the advance of the Tatars by the death of Hoolâgôo and the retreat of his army, Beybars despatched a force which effected the conquest of Armenia, and penetrated to the borders of Anatolia, a transient success which was speedily annulled by the advent of Abâkâ Khân, the son of Hoolâgôo. In the next war, Beybars again attacked the Christians, burning their churches and enslaving the people. He took Antioch, with horrible carnage, advanced to Hims and Hamâh, and thence returned to Cairo. After a campaign against the Tatars, he ravaged the country around Acre (the constant object of his attacks), and the "Assassins," so long the terror of dynasties, submitted to his power. About this time the Tatars renewed their inroads and besieged Beyrah; and in the year 671 Beybars took the field against them with two armies, one commanded by himself in person, the other by Kalâ-on El-Elfee. In the battle of Beyrah the sultan was completely victorious, and the Tatars fled to the mountains of Kurdistan. In consequence of this victory, Armenia again fell into his hands, and was given up to pillage. Abâkâ Khân afterwards was again repulsed at Beyrah. Nubia also about this time acknowledged the authority of Beybars. He died at Damascus in the year 676, after another expedition against Anatolia, attended with various success, in which the Tatars were leagued against him. Great military talents, coupled with the most indefatigable activity, Beybars certainly possessed, but he used his conquests numerically, on many occasions he ravaged whole provinces, and sacked many towns, putting great numbers of the inhabitants to the sword. The melancholy annals of the Crusades bear ample testimony to this fact, and while the example of other monarchs, and of the Franks themselves, may be urged as some palliation, nevertheless his barbarity remains an indelible blot on his character. In Egypt he endeavoured to reform abuses and suppress vice, and numerous public works were executed by his orders. Damietta was razed and rebuilt farther inland, and the mouth of the Nile was protected by a boom against sudden invasion. He repaired the fortifications of Alexandria and the Pharos, the mosque El-Azhar in Cairo, and the walls of the citadel, and built the great mosque known by his name to the north of the city.

The son and successor of Beybars, El-Melik Es-Sa'eed Barakeh Khân, was exiled after a short reign of two years, and a younger brother El-'Âdil Selâmish, raised to the throne, Kalâ-on El-Elfee acting as regent. This Memlook had married a daughter of Beybars, and was consequently nearly allied to the sultan. He nevertheless conspired against him, and was soon proclaimed king by the title of El-Melik El-Mansoor. Distinguished in former wars, he achieved many successes during his reign of ten years. On his accession he despatched an army to reduce disturbances in Syria, and took Damascus. Peace was thus established in that province; and in the year 680 he in person defeated a very superior force of Tatars and raised the siege of Rahabeh. Later in his reign (in the year 688) he besieged Tripoli, which for nearly two centuries had been in the possession of the Christians and was very rich and flourishing. The town was sacked and its unfortunate inhabitants put to the sword. His memory is still preserved in Cairo by his hospital and mad-house adjoining his fine mosque in the principal street of the city. This charitable institution he is said to have founded as an expiation for great severity towards the citizens in enforcing an obnoxious edict. His son, El-Ashraf Khaleel, rendered himself famous by the siege and capture (in the year 690) of Acre, the last stronghold of the Crusaders in Syria. Many thousands of its inhabitants were massacred; and 10,000 who pre-empted themselves before the sultan and demanded quarter were slaughtered in cold blood. He also took Erzeroum in 691, and two years after was assassinated in Egypt (A.D. 1294).

El-Melik En-Nâsir Mohammad, another son of Kalâ-on, succeeded him at the age of nine years. The regent Ketbooghâ, however, followed the example of Kalâ-on, and usurped the sovereignty, with the title El-Melik El-'Âdil. Pestilence and famine were followed by war with the Tatars, who again ravaged Syria. Ketbooghâ despatched an army against them, but the valour of his troops was unable to withstand overpowering numbers, and Lâgzen, Kalâ-on's governor in Syria, was driven into Egypt with an immense crowd of fugitives. Ketbooghâ was deposed on the allegation that he had not commanded in person, and El-Melik El-Mansoor Lâgzen was elevated in his stead. In little more than

two years this king was deposed in a conspiracy. His character was amiable, and he deserved a better return for the equity and kindness he showed to his subjects.

A short period of confusion then ensued, during which an emeer was proclaimed king En-Nâsir Mohammad, however, was at length recalled from his exile at Karak, and restored in the year 698. Having firmly established himself in Egypt, he led an army against the Tatars, but met with a severe reverse in the plains of Hims, a second expedition proved more fortunate, and En-Nâsir, then only nineteen years of age, gained a bloody and decisive victory over the enemy near Damascus, in the year 702. The battle lasted three days, during the first two the result was not decisive, although En-Nâsir held the field, on the third day the Tatars were utterly routed and pursued for many hours. The sultan on his entry into Cairo after this achievement was preceded by 1600 prisoners, each one carrying the head of a comrade slain in the combat, and 1000 other heads were borne on lances in the procession. En-Nâsir reigned until the year 707, when he went to Karak and voluntarily abdicated. He had long struggled against the control of two powerful emeers, Beybars and Sulâr; and in despair of throwing off their ascendancy, he then openly yielded the reins of government to those who had long really held them. Since this prince's accession the Christians and Jews of Egypt suffered the most severe persecution (excepting that of El-Hâkim) which had yet befallen them. In the year 700, they were ordered to wear blue and yellow turbans respectively, and forbidden to ride on horses or mules, or to receive any Government employment. The people took advantage of these measures to destroy many churches and synagogues. The churches continued shut for about a year, but some of those which had been destroyed were afterwards rebuilt at the request of Lascaris and other princes.¹ Another event of this period was a great earthquake which half ruined Cairo, giving it the appearance of a city demolished by a siege; Alexandria and other towns of Egypt, as well as Syria, also suffered from it considerably.

On the abdication of En-Nâsir, El-Melik El-Mudhafar Rukn-ed-Deen Beybars II. was saluted sultan; but ere long En-Nâsir recovered his courage, and having collected an army marched to Damascus, where he was acknowledged, and thence to Egypt, entering Cairo without opposition. El-Mudhafar had fled at his approach, and, never a favourite of the people, he was attacked on his exit from the metropolis, by a crowd of the citizens, who loaded him with abuse, and pelted him with stones. El-Nâsir now for the third time ascended the throne of Egypt, and took the entire authority into his own hands. The remainder of his life was a period of profound peace, during which he occupied himself in improving his dominions, and in embellishing Cairo. But another persecution of the Christians occurred in 721, and all the principal churches in Egypt were destroyed by certain fanatical Moslems. The sultan threatened a general massacre of the inhabitants of Cairo and El-Fustât; the Christians, however, took revenge themselves by setting fire to very many mosques and houses in the metropolis; much tumult ensued, and many Christians and Muslims were executed. The threats of the mob indeed induced En-Nâsir to permit the people to murder and plunder any Christian whom they might meet in the streets, and the oppressive rules before enacted were rigorously enforced, and made even more degrading.

The sons of En-Nâsir followed him in succession, but the reigns of most of them were short and troublous. El-Mansoor Seyf-ed-Deen Aboo-Bekr, El-Ashraf 'Alâ-ed-Deen Koojook, En-Nâsir Shihâb-ed-Deen Ahmad, Es-Sâlih 'Imâd-ed-Deen Ismâ'el, El-Kâmil Zeyn-ed-Deen Shâabân, and El-Mudhafar Zeyn-ed-Deen Hâggee were only raised to the throne to be either exiled or put to death. After these, the sultan Hasan deserves notice. He was deposed by his brother, Es-Sâlih Salâh-ed-Deen, whose minister was Sheykhoon, a man well known to students of Egyptian subjects, but he soon regained his authority, reigned seven years, and at length fell by the swords of his memlooks in the splendid mosque which he built in the open space beneath the citadel of Cairo. Four more Memlook kings bring the history to the accession of a new dynasty. These were El-Mansoor Nâsir-ed-Deen Hâggee (son of El-Mudhafar), deposed in six months, El-Ashraf Shâabân (son of Hasan), an unfortunate prince, whose reign passed away amid the intrigues of the *favourite* caliphs and the struggles of the now too powerful emeers, by whom he was ultimately strangled; his son, El-Mansoor 'Alâ-ed-Deen, the victim of similar troubles, in whose time the celebrated Barkook rose to the regency; and Es-Sâlih Hâggee, a brother of the last king. Exiled by Barkook, who was proclaimed sultan, he unsuccessfully endeavoured to recover his throne in the year 784; in 790 (A.D. 1388) he was restored, but he was soon once more dethroned, this time with the loss of his life.

The sultan Edh-Dhâhur Seyf-ed-Deen Aboo-Sa'eed Barkook was

¹ See *Modern Egyptians*, supplement, El-Makreeze, *Hist. des Sultans Mamlouks*, trs. Quatremère, tom. II., livr. II. 177, seqq., and, for further information on the persecutions of the Christians, Quatremère's *Mémoires sur l'Égypte*, tom. II. 220-266.

now undisputed master of Egypt. He was the first prince of the Dynasty of Burgee or Circassian Memlooks. As the preceding dynasty was founded by the Turkish Memlooks of Es-Sâlih Eiyoub, so this dynasty was composed of the Circassian slaves whom those kings from time to time bought with the view of strengthening their power. They were originally placed in garrison-towns, and hence their name *Burgee*, signifying "of a tower or castle." It is worthy of remark that, while many of the sultans of both these dynasties held an insecure tenure of power, many of the former met with a violent death, but few of the latter. The reign of Barkook is memorable for his war with Teemoor, or Teemoor-leng, commonly called by us Tamerlane, who had extended his conquests towards his dominions, but found him not unprepared, for he had foreseen the threatened danger. In the year 795, Karâ-Yoosuf, lord of El-Mederyeh, and Ahmad Ibn-Uweys, sultan of Baghaddâd, fled to his court for succour. The inhabitants of Edessa had been put to the sword, and Aleppo was menaced with a similar catastrophe, when Barkook at the head of his army came to its relief. Ahmad was reinstated in Baghaddâd, as a vassal of Barkook; and soon after the 'Othmânîco Bâyezid, commonly called by us Bajazet, concluded a treaty with the sultan of Egypt. His designs against India diverted Teemoor from his projects in Syria, but Barkook continued vigilant and by every means sought to insure the safety of his kingdom. He died suddenly in 801, much beloved by his subjects and regarded by less powerful chiefs as their strongest bulwark against the Tatar monarch. He was called "Sheykh" for his wisdom and learning, and combined with these qualities those of a skilful general and a good king. He was active, wary, and provident, and possessed the military talents of Beybars without his severity. He seems to have been fond of riches and display, and he certainly left his treasury in a very flourishing condition, besides much wealth in stores, slaves, horses, and the like.

His son, El-Melik En-Nâsir Abu-s-Sa'îdât Farag, fell a prey to intestine troubles and the inroads of the invader. He had overcome a revolt of the governor of Syria, when Teemoor again threatened that province. Karâ-Yoosuf and Ahmad sought refuge with the son of their former protector, and Farag's refusing to betray his guests gave occasion to the enemy to continue the war; a battle was fought, Farag was defeated, Aleppo and Hims fell into the hands of the victor, and the Egyptian forces returned and were concentrated in Egypt. Intimidated, however, by the fall of his ally Bajazet, Farag sent an embassy to Teemoor with presents and offers of amity, and at length concluded a peace at the sacrifice of territory. Teemoor died in the year 807 (A.D. 1405), and Farag was preparing an expedition to recover his Syrian possessions, when he was surprised in his palace by an insurrection, headed by his brother, 'Abd-el-'Azeez, and compelled to take to flight. The people believing that he had perished proclaimed El-Mansoor 'Abd-el-'Azeez his successor. In the space of less than three months, however, he was deposed in favour of Farag, who thenceforth reigned at Damascus, until the caliph El-Musta'een bi-lâh, at the instigation of the emeer Sheykh El-Mahmoodce, who had raised an army, boldly declared himself sultan, by an appeal to religion gained numbers to his side, instituted criminal proceedings against Farag on the plea of the exactions which he had been forced to levy for the conduct of the war against Teemoor, and accomplished his death. Farag was beheaded in the month of Safar in the year 815, and his corpse was left unburied. Abu-l-Mahâsin gives him the character of an extravagant, cruel, and voluptuous king.

El-Musta'een bi-lâh, with the title of El-Melik El-'Adil Abu-l-Fadl, began his reign well; but he had appointed El-Mahmoodce his vizir as a reward for his services, and this powerful and vigorous chief soon obliged him to abdicate and eventually exiled him to Alexandria, where he passed the remainder of his days.

El-Melik El-Mu-eyyad Abu-n-Nasr Sheykh El-Mahmoodce (originally a memlook of Barkook's) waged three successful wars in Syria, in the first of which he was guilty of a breach of faith in putting to death the governor of Damascus and part of the garrison of that city, after they had surrendered on promise of safety. He reigned peacefully in Egypt, and his name is recorded as that of a king who studied the happiness of his subjects and favoured the learned, who counted him among their number. But he was avaricious; although one might judge the contrary from his beautiful mosque and the minarets over the Bâb-Zuweyleh in Cairo, held to be among the chief ornaments of the city.

Three kings followed in rapid succession:—El-Madhaffar Ahmad, a son of El-Mu-eyyad, under two years of age at his accession, Edh-Dhâhir Tatar, and his infant son, Es-Sâlih Mohammad, who was deposed by Barsâbay Ed-Dukmâkee. This Memlook assumed the title of El-Melik El-Ashraf, and worthily continued the prosperous reign of El-Mu-eyyad. In power and virtue he ranks second only to Barkook among all the kings of this dynasty. He is known in European history by his expedition in 827 (A.D. 1424) against John III., king of Cyprus, who became his vassal, and by the part he took, about seven years later, in the dissensions of the house of Savoy and the government of Cyprus. He ruled for seventeen

years with great clemency, and died in 841. El-'Azeez Yoosuf, his son, was deposed by El-Mansoor Abou-Sa'eed Jakmak El-'Alâ-ee, a good prince, and a patron of the learned. After a peaceful reign he abdicated at the age of about eighty years in favour of his son, El-Mansoor Abu-s-Sa'îdât 'Othmân, who was overthrown by the intrigues of the caliph El-Kâim bi-amr-ilâh, and was succeeded by an aged Memlook, El-Ashraf Abu-n-Nasr Eynâl, followed by his son, El-Mu-eyyad Shihâb-ed-Deen Abu-l-Fet-h Ahmad. Edh-Dhâhir Seyf-ed-Deen-Khoshkadam, a Greek by birth, superseded him, reigning himself for seven years, with equity and benignity, presenting a contrast to the cruelty and oppression of his appointed successor, Ed-Dhâhir Abou-Sa'eed Bilbây El-'Alâ-ee, which caused the latter's fall and the elevation of the sultan Abou-Sa'eed Temerbeg Edh-Dhâhree, who, in his turn, was deposed to make room for El-Ashraf Kâit Bey, a prince who deserves especial notice for his struggles with the Turks, whereby the conquest of Egypt by the Porte was deferred for a few years. After a period of quiet which followed his accession, he was alarmed by the victory gained by Mehemet II. over his ally the king of Persia, and posted a considerable force on the frontier of Syria. The successes of the conqueror of Constantinople made him desire to abdicate; but the emeers prayed him to defend his rights, and he consequently prepared for the war. The death of Mehemet, and the dissensions between Bajazet II and Jem (or Zizim) temporarily relieved him of these apprehensions. The fall of Jem, however, and his arrival at the Egyptian court, implicated the Memlook sultan in the quarrel, and on the final overthrow of this prince Kâit Bey made sure of a war with the more fortunate Bajazet, and himself began aggressive measures, intercepted the Turkish caravan of pilgrims, and an ambassador from India who was on his way to Constantinople with presents, and took Tarsus and Adanoh. A remonstrance from Bajazet was answered by a successful attack on his Asiatic commander, 'Alâ-ed-Dowleh. In the meantime Tarsus and Adanoh were recovered from him; but the emeer El-Ezbekee, to whom was entrusted the conduct of all future wars, being despatched against these towns, retook them, defeated an army sent to chastise him, and annexed Karamania. Another force was speedily equipped, and took the field in 893; conditions of peace were refused, and considerable success attended the Turkish arms. El-Ezbekee was, therefore, again ordered to Syria; a Turkish squadron conveying troops was dispersed, and at Tarsus he gave battle. The result was at first unfavourable to the Memlooks, whose commander, however, rallied them under cover of the night, and succeeded in surprising and totally defeating the Turks. Long negotiations followed this victory; and at length Kâit Bey, who was always most anxious for peace, ceded the disputed towns of Tarsus and Adanoh, and secured repose during the rest of his days. He died in 901, having designated El-Melik En-Nâsir Abu-s-Sa'îdât Mohammad as his successor. This weak and barbarous king was put to death after four years, during which he was deposed, and Kânsouh, surnamed Khamsameeyeh, and Edh-Dhâhir Abu-n-Nasr Kânsouh were successively installed. The first reigned but eleven days, and the latter abdicated after five months of great difficulty and danger. On the death of En-Nâsir, El-Ashraf Kânsouh Jambâkî was elevated to the throne, but six months sufficed to accomplish his fall, and he was fortunate in preserving his life. The next sultan, El-Melik El-'Adil Too-mân Bey, was acknowledged both in Egypt and Syria. He, however, was overthrown and killed in a few months.

The Memlooks now compelled Kânsouh El-Ghooree to assume the dangerous dignity, with the title of El-Melik El-Ashraf. This prince very unwillingly yielded. His previous life shows him to have been both virtuous and learned; and he proved himself to be an able ruler. After an unsuccessful expedition against the Portuguese in the East, he reigned in peace until the year 915, when Kerkood, the father of Selim I., the Turkish sultan, obtained his protection and assistance. Events similar to those which accompanied the end of Jem followed; and Selim availed himself of a pretext to declare war against Egypt. The first reverse which the Egyptians suffered occurred to an army commanded by 'Alâ-ed-Dowleh, formerly defeated by Kâit Bey, but now in the pay of El-Ghooree. The winter was passed by the latter in preparing energetically for the inevitable struggle, and in the spring he advanced in person. Selim, on his part, pretended to march towards Persia; but at the same time he sent to demand of El-Ghooree wherefore he opposed his passage and commanded in person on the frontier. El-Ghooree replied that his was merely an army of observation, and that he was desirous of mediating between Selim and Ismâ'el Shâh. Selim, however, rapidly advanced, refused to listen to an attempt at negotiation, and was met by El-Ghooree on the plain of Marj-Dâbik, near Aleppo. A long and sanguinary battle ensued, and victory declared for neither side, until Kheyr Bey, commanding the right wing, and El-Ghazâlce the left, of the Egyptian army, basely deserted to the enemy with their troops. The centre then gave way and fled in utter confusion, notwithstanding the efforts of the sultan to rally them. He was trampled to death by his routed cavalry, while (according to some) in the act of prayer.

This event took place on the 26th of Regeh 922 (A.D. 1516). With his death Egypt lost her independence. The shattered remains of the army collected in Cairo. Toomán Bey, a nephew of the deceased king, was elected sultan, and at once determined on every resistance to the conqueror. His general in Syria, El-Ganbardee, disputed the road with Selim step by step, and Toomán Bey awaited his arrival near Cairo. Between El-Khánkah and the metropolis, at the village of Er-Reydíneeyeh, the opposing armies joined battle, on the 29th of Zu-l-Heggeh (January 1, 1517). The fall of a favourite general, Sinán Pasha, infuriated the Turks, and the brilliant bravery of the Memlooks availed them not. Immense numbers of them were slain by their enemies in the pursuit, and the survivors reunited in Cairo. El-Ganbardee, however, sacrificed his fame by joining the victor. The Turkish army paused for rest; and time was thus given to Toomán Bey to hire Arabs at a great cost to replenish his thinned ranks. Selim now passed to the west of Cairo. A night surprise conducted by Toomán failed, but he succeeded in putting to the sword a great many Turks. He fortified himself in the city, and a house-to-house combat ensued, the Memlooks defending every foot with the energy of despair, the citadel fell by assault, and the unfortunate Toomán effected his escape towards Alexandria; but on the way he was taken by Arabs, given up to El-Ganbardee and another, and brought in chains to Selim, who at first received him with honour, but afterwards falsely accused him of conspiring against him, and, with the cruelty and perfidy characteristic of his race, hung him over the Bab-Zaweyleh, the place of execution for common malefactors. Thus miserably perished the last independent ruler of Egypt, who possessed the best qualities of his line, and whose noble defence of his kingdom would have secured to him the commiseration of any but a Turk.

In reviewing the period during which Egypt was governed by independent Muslim princes, it is necessary to consider the spirit of the times and the people over whom they ruled. They succeeded to the government of countries worn out by incessant warfare, overrun by savage hordes, and debased by the rule of the Lower Empire. Egypt had long struggled against the slavery to which it was condemned, and the history of the last three dynasties of Pharaohs evinces the patriotism which yet animated her people. But the successive tyranny of the Persians, the Greeks, and the Romans appears to have annihilated their nationality, and when the Arabs invaded the country, these causes, combined with religious strife, induced the people to afford to the conquerors every assistance in their power. But the changeable rule of the lieutenants and the troubles of the caliphs debarred Egypt (except at times under the Benes-Tooloon and the Ikhsheedeeyeh) from profiting by the enlightenment of the race who held the dominion over it, until the conquest by the Fátímees. The caliphs of that dynasty contributed in a great degree to restore to Egypt some portion of its ancient prosperity, and with the house of Eiyoub it attained its greatest military glory under the Muslims; but the edifices erected during the rule of the two dynasties of Memlook kings, the libraries collected in Cairo at that period, and the learned men who then flourished would point to it as the age in which literature and the arts were cultivated with the most success, a sure evidence of the internal prosperity of any country. This is the more surprising when we consider the state of Syria, which had long before their accession fallen a prey to intestine wars and the ravages of the Tatars, the Crusaders, and other invaders, and also bear in mind the constitution of their government, in which the more powerful chiefs were constantly aiming at the supreme authority; and the practice of purchasing memlooks, and rearing them in the households of the great to enable their masters to maintain their ascendancy augmented the number of these aspirants to the throne. These slaves were, unlike the Bahrees (who were the Turkish Memlooks of Es-Sálih Eiyoub), chiefly Circassians, who afterwards composed the Second (or Burgee) Dynasty. Many of the Memlook sultans rivalled in military achievements the great Saladin, and even penetrated further than he in their foreign expeditions. In Cairo are still seen the finest specimens of Arab architecture, almost all dating during the period comprised under the domination

of the two Memlook dynasties; the libraries of the mosques, and the private collections of that city, though grievously injured since the Turkish conquest, are or very recently were the best and most considerable of those of Egypt or Syria;¹ and, as before remarked, the university El-Azhar is still, owing to the fostering care of these sultans, the principal seat of learning of the Eastern world. In this sketch of the history of Egypt we have given no account of the state of commerce, taxation, &c., under the Muslims. Those only who have read the Arab histories of this and other Eastern countries can appreciate the general fallacy of the conclusions based on their authority.

It would be tedious and unprofitable to follow the details of Turkish misrule and tyranny which are from this time presented to the student of Egyptian history. Although Selim had apparently destroyed the power of the Memlooks, he thought it wise to conciliate them, and to appoint twenty-four beys over the military provinces of that number into which he divided Egypt, subject to the supreme control of a pasha, whose council was formed of seven Turkish chiefs (ójaklees), while one of the beys held the post of Sheykh el-Beled, or Governor of the Metropolis, an officer who became an object of hatred to the other chiefs. This system was begun by Selim, and completed by his successor. For nearly two centuries the successive pashas were mostly obeyed, but the ambition of becoming Sheykh el-Beled was the fruitful cause of intrigue and murder. The Memlooks who then held power in Egypt were called the Ghuzz, that being the name of the tribe to which they are said to have at first generally belonged; and they continually bought slaves, of Circassian or Georgian race, to supply the place of children, for they did not intermarry with natives of Egypt, and women of more northern climates are generally either barren or bear sickly offspring in that country. Thus they lacked the surest source of power; few possessed any family ties, but at the same time the slaves in general were remarkably faithful to their patrons. After two centuries, the beys gradually increased in power, until the authority of the pasha was almost nominal, and the government became a military oligarchy. This brings us to the rise of the celebrated Ali Bey. He was created Sheykh el-Beled in A.H. 1177; but, having revenged himself on an old enemy who had assassinated Ali's master, to whom he owed his elevation to the rank of bey, he shortly after fled to Syria, and took refuge with the governor of Jerusalem, and thence went to Acre, where the Sheykh Dháhir became his friend, and that same year he returned to Cairo in his former capacity of Sheykh el-Beled. In 1179 his enemies again compelled him to flee, and he betook himself this time to El-Yemen, once more to return to Egypt; after which he gained increased power. His favourite memlook, Mohammad Abou-Dhahab, proved ungrateful, and, while enjoying the highest power, entered into a conspiracy against his life; but after receiving the presents of the hostile beys, he denounced them to his master, who would not listen to warnings of his meditated treachery.

In the year 1182 (A.D. 1768) the Porte demanded the assistance of Ali Bey in the Russian war, an order which he was about to obey, when he was apprised of the departure of a messenger with a firmán demanding his head, he having been falsely accused at Constantinople of intending to aid the Russians and throw off his allegiance. He caused the bearer of this order to be waylaid and put to death, and having possessed himself of the firmán, he con-

¹ It should, however, be mentioned that many of the most precious of their contents are plunder brought from the libraries of mosques in Syria, as is proved by seals which they bear.

vened the beys, showed them the document, and aided by those of his own household persuaded the council to expel the pasha, and declare Egypt independent. The Sheykh Dháhir took part in this rebellion, and the pasha of Damascus was beaten by him between Mount Lebanon and Tiberias. A period of good but vigorous government and of tranquillity followed these events in Egypt, notwithstanding the very heavy imposts levied for the replenishment of the treasury; and Ali's generals gained for him extended power abroad. Mohammad Abou-Dhahab was despatched to Arabia, and entered Mecca, where the Shereef was deposed; and another bey traversed the eastern shores of the Red Sea. After the expedition to Arabia, Mohammad Bey marched into Syria to assist the Sheykh Dháhir against the Porte, and the co-operation of the Russians was demanded. A successful campaign terminated before the walls of Damascus, the siege of which was abandoned when nearly brought to a close, and Mohammad Bey returned with large forces to Egypt. This man, loaded with benefits by his patron, now openly rebelled; and being joined by Ali's enemies, at the head of whom was Ismail, chief of the guard, he advanced on Cairo, and Ali escaped to his steady ally, Shoykh Dháhir, the prince of Acre. These events took place the year 1186. Mohammad Bey was then declared Sheykh el-Beled. Ali Bey, in the meanwhile, in conjunction with his ally, gained various advantages in Syria, and, on the information that his return was desired in Egypt, he collected a small force, assisted by Sheykh Dháhir and a Russian squadron, and determined on attempting to recover his power. He, however, fell into an ambuscade near Es-Sáliheeyeh, and was wounded by one of his memlooks named Murád (afterwards Murád Bey), carried to the citadel, and poisoned by Mohammad Bey. Thus terminated the career of the famous Ali Bey, a man whose energy, talents, and ambition bear a strong resemblance to those of the later Mehemet Ali.

Mohammad Bey continued Sheykh el-Beled, tendered his allegiance to the Porte, and was invested with the pashalik. He then entered Syria, and severely chastised Sheykh Dháhir, taking Gaza, Joppa, and Acre itself. Joppa was taken by assault, and suffered a massacre of its inhabitants, and Acre was pillaged. At the latter place the pasha suddenly died. His mosque in Cairo is the latest fine specimen of Arab architecture, and is not unworthy of its better days.

The chief competitors for power were now Ismail, Ibrahim, and Murád, the first of whom was speedily expelled, the contest continuing between the two latter beys. Ibrahim at length succeeded in causing himself to be proclaimed Sheykh el-Beled, and Murád contented himself with the office of Emeer el-Hágg, or chief of the pilgrims; but this arrangement was not destined to be of long continuance; a violent quarrel resulted in a recourse to arms, and that again in a peace of three years' duration, during which the two beys held an equal sway. In the year 1200 the Porte despatched Hassan Capitan (properly Kapoodán) Pasha (or High Admiral), with a Turkish force, to reduce the turbulent Memlooks to obedience, and to claim the annual tribute. Murád Bey was defeated at Er-Rahmáneyeh, and the Turks advanced to Cairo, desolating the country, and acting according to their almost invariable practice on such occasions. The metropolis opened its gates to Hasan Pasha, who determined on pursuing the beys to Upper Egypt, whither he despatched a large portion of his army, and a sanguinary conflict took place. But a war with Russia recalled this commander to Constantinople. Ismail was again created Sheykh el-Beled, and he held that post until the terrible plague of the year 1205, in which he perished, and hence it is commonly called the "Plague of Ismail." His death caused the return of Ibrahim and Murád; and

eight years after, intelligence of the arrival at Alexandria of a French army of 36,000 men, commanded by General Bonaparte, united these chiefs in a common cause.

On the 18th May 1798, this expedition, consisting of 13 sail of the line, 6 frigates, and 12 vessels of a smaller size, sailed from Toulon, and made the coast of Egypt on the 1st July. The troops were landed near Alexandria, and the city fell by assault on the 5th of that month. The French conquest and occupation of Egypt belong to European history; a recapitulation of the principal events of the period will therefore suffice in this place. The Memlooks affected to despise their antagonist, and hastened to chastise him: at Shibirrees they attacked the French and were repulsed; but, nothing discouraged, they collected all their forces, exceeding 60,000 men, under the command of Murád, and entrenched themselves at Embábel, opposite Cairo. Here was fought the battle which has been dignified with the name of that of the Pyramids. European tactics completely bewildered the Memlooks: their famous cavalry was received on the bayonets of the French squares; a galling fire of grape and musketry mowed down their ranks; and of this great army only about 2500 horse escaped with Murád Bey, while 15,000 men of all arms fell on the field of battle. Having made himself master of Cairo, Bonaparte despatched General Desaix to effect the conquest of Upper Egypt, and the success of the Eastern expedition seemed secured. But, ten days after the victory of Embábel, the battle of the Nile annihilated the French fleet in Abou-Keer (Aboukir) Bay, and most materially influenced the future conduct of the war. On this point, Napoleon himself says, "La perte de la bataille d'Aboukir eut une grande influence sur les affaires d'Egypte et même sur celles du monde; la flotte Française sauvée, l'expédition de Syrie n'éprouvait point d'obstacles, l'artillerie de siège se transportait sûrement et facilement au-delà du désert, et Saint-Jean-d'Acre n'arrêtait point l'armée Française. La flotte Française détruite, le divan s'enhardit à déclarer la guerre à la France. L'armée perdit un grand appui, sa position en Egypte changea totalement, et Napoléon dut renoncer à l'espoir d'asseoir à jamais la puissance Française dans l'Occident par les résultats de l'expédition d'Egypte."¹ The disastrous expedition into Syria, undertaken for the purpose of frustrating the efforts of Sir Sydney Smith before Alexandria, and of Jezzár Pasha, who was advancing from Acre, still further obscured Napoleon's prospects in the East, and the victory soon after obtained by him over the Ottoman army at Abou Keer, the second defeat of Murád Bey, and various successes over the Turks, enabled the French general Kléber (Napoleon having left for Europe after the first of these events) to set on foot negotiations for an honourable evacuation of the country. But when the convention was already signed, and the French were about to quit Cairo, Lord Keith signified to Kléber that Great Britain would not consent to the terms of the treaty; and although this refusal was afterwards rescinded, Kléber considered that the withdrawal came too late: he totally defeated 70,000 men under the grand vizir at Heliopolis, and returned to Cairo to quell an insurrection of the inhabitants. This distinguished officer was about this time assassinated in the garden of his palace by a fanatic, who was impaled in the great square (then a lake) called the Ezbekeeyeh, in Cairo, and miserably lingered for the space of three days before death put an end to his sufferings. Under Kléber's administration, Egypt began to resume its former prosperity; by his conciliatory and good government much prejudice against the French was overcome; by ceding a part of Upper Egypt to Murád, he gained the good will of that chief, who gave him no cause to regret

¹ Napoleon, *Mémoires*, t. ii.

this politic step; while under his auspices the "savans" of the Institute of Egypt collected the valuable mass of information embodied in the "great French work," the *Description de l'Égypte*.

On the death of Kléber, General Menou succeeded to the command, and although he afterwards conducted the defence of the country with much valour, yet to his injudicious administration, and his want of military talent, we must mainly ascribe the determination of the British Government to attempt the expulsion of the French from Egypt, and the rapid success of the campaign that ensued. On the 2d of March 1801 an army under Sir Ralph Abercromby arrived in Abou-Keer Bay, and made good a landing in the face of a well-disposed French force, which offered every possible resistance. The memorable battle of Alexandria, in which Abercromby fell, decided the fate of the war. A bold march, executed with talent, effected the capitulation of Cairo; Alexandria surrendered on the 1st of September, and the French sailed from the shores of Egypt in the course of that month.¹ General Hutchinson had taken the command of the English expedition, afterwards reinforced by a detachment from India under General Baird; and the army of the grand vizir, and that of the capitan-pasha, with the troops of Ibrahim Bey (Murád having died of the plague), had co-operated in the measures which led to the evacuation of the country by Menou.

The history now requires that we should mention the early career of a man who subsequently ruled the destinies of Egypt for a period of nearly forty years. Mehemet Ali Pasha was born in A.H. 1182 (A.D. 1768-9) at Cavalla, a small sea-port town of Albania. On the death of his father, in early life, he was brought up in the house of the governor of the town, who, as a reward for military prowess, gave him his daughter in marriage. By her he had, it is said, his three eldest sons, Ibrahim,² Toosoon, and Ismail. Having attained the rank of büluk-báshee (or head of a body of infantry), he became a dealer in tobacco, until, in his thirty-third year, he was despatched to Egypt with his patron's son, Ali Ághá, and 300 men, the contingent furnished by his native place to the Turkish expedition against the French; and soon after his arrival in that country he succeeded, on the return of Ali Ághá, to the command, with the nominal rank of beeñbáshee (or chief of a thousand men).

Soon after the evacuation of Egypt by the French, that unfortunate country became the scene of more severe troubles, in consequence of the unwarrantable attempts of the Turks to destroy the power of the Ghuzz. In defiance of promises to the English Government, orders were transmitted from Constantinople to Hoseyn Pasha, the Turkish high admiral, to ensnare and put to death the principal beys. Invited to an entertainment, they were, according to the Egyptian contemporary historian El-Gabartee, attacked on board the flag-ship; Sir Robert Wilson and M. Mengin, however, state that they were fired on, in open boats, in the bay of Abou-Keer. They offered an heroic resistance, but were overpowered, and some made prisoners, some killed, while some, including the afterwards celebrated 'Osmán Bey El-Bardeesee, escaped in a boat, and sought refuge with the English, who at that time occupied Alexandria. General Hutchinson, informed of this treachery, immediately assumed threatening measures against the Turks, and in consequence, the killed, wounded, and prisoners

were given up to him. Such was the commencement of the disastrous struggle between the Memlooks and the Turks.

Mohammad Khusruf was the first pasha after the expulsion of the French. The form of government, however, was not the same as that before the French invasion, for the Ghuzz were not reinstated. The pasha, and through him the sultan, endeavoured on several occasions either to ensnare them or to beguile them into submission; but these efforts failing, Mohammad Khusruf took the field, and a Turkish detachment 14,000 strong, despatched against them to Demenhor, whither they had descended from Upper Egypt, was defeated by a small force under El-Elfee; or, as Mengin says, by 800 men left by El-Elfee under the command of El-Bardeesee. Their ammunition and guns fell into the hands of the Memlooks.

In March 1803 the British evacuated Alexandria, and Mohammad Bey El-Elfee accompanied them to England to consult respecting the means to be adopted for restoring the former power of the Ghuzz. About six weeks after, the Arnoot (or Albanian) soldiers in the service of Khusruf tumultuously demanded their pay, and surrounded the house of the defterdár, who in vain appealed to the pasha to satisfy their claims. The latter opened fire from the artillery of his palace on the insurgent soldiery in the house of the defterdár, across the Ezbekeeyeh. The citizens of Cairo, accustomed to such occurrences, immediately closed their shops, and the doors of the several quarters, and every man who possessed any weapon armed himself. The tumult continued all the day, and the next morning a body of troops sent out by the pasha failed to quell it. Táhir, the commander of the Albanians, then repaired to the citadel, gained admittance through an embrasure, and, having obtained possession of it, began to cannonade the pasha over the roofs of the intervening houses, and then descended with guns to the Ezbekeeyeh, and laid close siege to the palace. On the following day, Mohammad Khusruf made good his escape, with his women and servants and his regular troops, and fled to Damietta by the river. This revolt marks the commencement of the rise of Mehemet Ali to power in Egypt, and of the breach between the Arnoots and Turks which ultimately led to the expulsion of the latter.

Táhir Pasha assumed the government, but in twenty-three days he met with his death from exactly the same cause as that of the overthrow of his predecessor. He refused the pay of certain of the Turkish troops, and was immediately assassinated. A desperate conflict ensued between the Albanians and Turks; and the palace was set on fire and plundered. The masters of Egypt were now split into these two factions, animated with the fiercest animosity against each other. Mehemet Ali became the head of the former, but his party was the weaker, and he therefore entered into an alliance with Ibrahim Bey, and 'Osmán Bey El-Bardeesee. A certain Ahmad Pasha, who was about to proceed to a province in Arabia, of which he had been appointed governor, was raised to the important post of pasha of Egypt, through the influence of the Turks and the favour of the sheykhs; but Mehemet Ali, who with his Albanians held the citadel, refused to assent to their choice; the Memlooks moved over from El-Geezeh, and Ahmad Pasha betook himself to the mosque of Ez-Záhir, which the French had converted into a fortress. He was compelled to surrender by the Albanians; the two chiefs of the Turks who killed Táhir Pasha were taken with him and put to death, and he himself was detained a prisoner. In consequence of the alliance between Mehemet Ali and El-Bardeesee, the Albanians gave the citadel over to the Memlooks; and soon after, these allies marched against Khusruf Pasha, who having been joined by a con-

¹ Very many of the French had either married Muslim women, or bought concubine slaves of the same faith, whom, on their departure, they left behind them; and these unfortunates were forthwith tied up in irons and drowned.

² Ibrahim is, however, believed by many, or most, to have been the wife's son by a former husband.

siderable body of Turks, and being in possession of Damietta, was enabled to offer an obstinate resistance. After much loss on both sides, he was taken prisoner and brought to Cairo; but he was treated with respect. The victorious soldiery sacked the town of Damietta, and were guilty of the barbarities usual with them on such occasions.

A few days later, Ali Pasha El-Tarâbulusee landed at Alexandria with an imperial firman constituting him pasha of Egypt, and threatened the Beys, who now were virtual masters of Upper Egypt, as well as of the capital and nearly the whole of Lower Egypt. Mehmet Ali and El-Bardeesee therefore descended to Rosetta, which had fallen into the hands of a brother of Ali Pasha, and having recovered the town and captured its commander, El-Bardeesee purposed to proceed against Alexandria; but the troops required arrears of pay which it was not in his power to give, and the pasha had cut the dyke between the Lakes of Abou-Keer and Mareotis, thus rendering the approach to Alexandria more difficult. El-Bardeesee and Mehmet Ali therefore returned to Cairo. The troubles of Egypt were now increased by an insufficient inundation, and great scarcity prevailed, aggravated by the exorbitant taxation to which the beys were compelled to resort in order to raise money to pay the troops; while murder and rapine prevailed to a frightful extent in the capital, the riotous soldiery being under little or no control. In the meantime, Ali Pasha, who had been behaving in an outrageous manner towards the Franks in Alexandria, received a khatt-i-shereef from the sultan, which he sent by his secretary to Cairo. It announced that the beys should live peaceably in Egypt, with an annual pension each of fifteen purses and other privileges, but that the government should be in the hands of the pasha. To this the beys assented, but with considerable misgivings; for they had intercepted letters from Ali to the Albanians, endeavouring to alienate them from their side to his own. Deceptive answers were returned to these, and Ali was induced by them to advance towards Cairo at the head of 2500 men. The forces of the beys, with the Albanians, encamped near him at Shalakân, and he fell back on a place called Zafeyteh. They next seized his boats conveying soldiers, servants, and his ammunition and baggage; and, following him, they demanded wherefore he brought with him so numerous a body of men, in opposition to usage and to their previous warning. Finding they would not allow his troops to advance, forbidden himself to retreat with them to Alexandria, and being surrounded by the enemy, he would have hazarded a battle, but his men refused to fight. He therefore repaired to the camp of the beys, and his army was compelled to retire to Syria. In the hands of the beys, Ali Pasha again attempted treachery. A horseman was seen to leave his tent one night at full gallop; he was the bearer of a letter to 'Osmân Bey Hasan, the governor of Kinê. This offered a fair pretext to the Memlooks to rid themselves of a man whose antecedents and present conduct proved him to be a perfidious tyrant. He was sent under a guard of forty-five men towards the Syrian frontier; and about a week after, news was received that in a skirmish with some of his own soldiers he had fallen mortally wounded.

The death of Ali Pasha produced only temporary tranquillity; in a few days the return of Mohammad Bey El-Elfee (called the Great or Elder) from England was the signal for fresh disturbances, which, by splitting the Ghuzz into two parties, accelerated their final overthrow. An ancient jealousy existed between El-Elfee and the other most powerful bey, El-Bardeesee. The latter was now supreme among the Ghuzz, and this fact considerably heightened their old enmity. While the guns of the citadel,

those at Masr El-'Ateekah, and even those of the palace of El-Bardeesee, were thrice fired in honour of El-Elfee, preparations were immediately commenced to oppose him. His partisans were collected opposite Cairo, and El-Elfee the Younger held El-Geezeh; but treachery was among them; Hoseyn Bey El-Elfee was assassinated by emissaries of El-Bardeesee, and Mehmet Ali, with his Albanians, gained possession of El-Geezeh, which was, as usual, given over to the troops to pillage. In the meanwhile El-Elfee the Great embarked at Rosetta, and not apprehending opposition, was on his way to Cairo, when a little south of the town of Manoof he encountered a party of Albanians, and with difficulty made his escape. He gained the eastern branch of the Nile, but the river had become dangerous, and he fled to the desert. There he had several hair-breadth escapes, and at last secreted himself among a tribe of Arabs at Râs-el-Wâdeê. A change in the fortune of El-Bardeesee, however, favoured his plans for the future. That chief, in order to satisfy the demands of the Albanians for their pay, gave orders to levy heavy contributions from the citizens of Cairo; and this new oppression roused them to rebellion. The Albanians, alarmed for their safety, assured the populace that they would not allow the order to be executed; and Mehmet Ali himself caused a proclamation to be made to that effect. Thus the Albanians became the favourites of the people, and took advantage of their opportunity. Three days later they beset the house of the aged Ibrahim Bey, and that of El-Bardeesee, both of whom effected their escape with difficulty. The Memlooks in the citadel directed a fire of shot and shell on the houses of the Albanians which were situated in the Ezbekeyeh; but on hearing of the flight of their chiefs, they evacuated the place; and Mehmet Ali, on gaining possession of it, once more proclaimed Mahomet Khusruf pasha of Egypt. For one day and a half he enjoyed the title; the friends of the late Tâhir Pasha then accomplished his second degradation,¹ and Cairo was again the scene of terrible enormities, the Albanians revelling in the houses of the Memlook chiefs, whose harems met with no mercy at their hands. These events were the signal for the reappearance of El-Elfee.

The Albanians now invited Ahmad Pasha Khursheed to assume the reins of government, and he without delay proceeded from Alexandria to Cairo. The forces of the partisans of El-Bardeesee were ravaging the country a few miles south of the capital and intercepting the supplies of corn by the river; a little later they passed to the north of Cairo and successively took Bilboys and Kalyoob, plundering the villages, destroying the crops, and slaughtering the herds of the inhabitants. Cairo was itself in a state of tumult, suffering severely from a scarcity of grain, and the heavy exactions of the pasha to meet the demands of his turbulent troops, at that time augmented by a Turkish detachment. The shops were closed, and the unfortunate people assembled in great crowds, crying Yâ Lateef! Yâ Lateef! "O Gracious [God]!" El-Elfee and 'Osmân Bey Hasan had professed allegiance to the pasha; but they soon after declared against him, and they were now approaching from the south; and having repulsed Mehmet Ali, they took the two fortresses of Turâ. These Mehmet Ali speedily retook by night with 4000 infantry and cavalry; but the enterprise was only partially successful. On the following day the other Memlooks north of the metropolis actually penetrated into the suburbs; but a few days later were defeated in a battle fought at Shubrâ, with heavy loss

¹ Khusruf Pasha afterwards filled with credit several of the highest offices at Constantinople. He died on the 1st of February 1855. He was a bigot of the old school, strongly opposed to the influence of Western civilization, and consequently to the assistance of France and England in the Crimean war.

on both sides. This reverse in a measure united the two great Memlook parties, though their chiefs remained at enmity. El-Bardeesee passed to the south of Cairo, and the Ghuzz gradually retreated towards Upper Egypt. Thither the pasha despatched three successive expeditions (one of which was commanded by Mehemet Ali), and many battles were fought, but without decisive result.

At this period another calamity befell Egypt; about 3000 Delees arrived in Cairo from Syria. These troops had been sent for by Khursheed in order to strengthen himself against the Albanians; and the events of this portion of the history afford sad proof of their ferocity and brutal enormities, in which they far exceeded the ordinary Turkish soldiers and even the Albanians. Their arrival immediately recalled Mehemet Ali and his party from the war, and instead of aiding Khursheed was the proximate cause of his overthrow.

Cairo was ripe for revolt, the pasha was hated for his tyranny and extortion, and execrated for the deeds of his troops, especially those of the Delees. The sheykhs enjoined the people to close their shops, and the soldiers clamoured for pay. At this juncture a firmán arrived from Constantinople conferring on Mehemet Ali the pashalic of Jiddeh; but the occurrences of a few days raised him to that of Egypt.

On the 12th of Safar 1220 (May 1805) the sheykhs, with an immense concourse of the inhabitants, assembled in the house of the kadee, and the 'Ulemá, amid the prayers and cries of the people, wrote a full statement of the heavy wrongs which they had endured under the administration of the pasha. The 'Ulemá, in answer, were desired to go to the citadel, but they were apprised of treachery, and on the following day, having held another council at the house of the kadee, they proceeded to Mehemet Ali, and informed him that the people would no longer submit to Khursheed. "Then whom will ye have?" said he. "We will have *thee*," they replied, "to govern us according to the laws; for we see in thy countenance that thou art possessed of justice and goodness." Mehemet Ali seemed to hesitate, and then complied, and was at once invested. On this, a bloody struggle commenced between the two pashas. Cairo had before experienced such conflicts in the streets and over the housetops, but none so severe as this. Khursheed, being informed by a messenger of the insurrection, immediately laid in stores of provisions and ammunition, and prepared to stand a siege in the citadel. Two chiefs of the Albanians joined his party, but many of his soldiers deserted. Mehemet Ali's great strength lay in the devotion of the citizens of Cairo, who looked on him as their future deliverer from their afflictions; and great numbers armed themselves, advising constantly with Mehemet Ali, having the seyyid 'Omar and the sheykhs at their head, and guarding the town at night. On the 19th of the same month, Mehemet Ali besieged Khursheed. Retrenchments were raised, and the lofty minaret of the mosque of the sultan Hasan was used as a battery whence to fire on the citadel, while guns were also posted on the mountain in its rear. After the siege had continued many days, Khursheed gave orders to cannonade and bombard the town; and for six days his commands were executed with little interruption, the citadel itself also lying between two fires. Mehemet Ali's position at this time was very critical: his troops became mutinous for their pay; the siláhdár, who had commanded one of the expeditions against the Ghuzz, advanced to the relief of Khursheed; and the latter ordered the Delees to march to his assistance. The firing ceased on the Friday, but recommenced on the eve of Saturday and lasted until the next Friday. On the day following, news came of the arrival at Alexandria of a messenger from Constantinople. The ensuing night in Cairo presented a curious spectacle,

many of the inhabitants gave way to rejoicing, in the hope that this envoy would put an end to their miseries, and fired off their weapons as they paraded the streets with bands of music. The siláhdár, imagining the noise to be a fray, marched in haste towards the citadel, while its garrison sallied forth, and commenced throwing up retrenchments in the quarter of 'Arab-el-Yesár, but were repulsed by the armed inhabitants and the soldiers stationed there; and during all this time, the cannonade and bombardment from the citadel, and on it from the batteries on the mountain, continued unabated.

The envoy brought a firmán confirming Mehemet Ali, and ordering Khursheed to repair to Alexandria, there to await further orders; but this he refused to do, on the ground that he had been appointed by a Khatt-i-shereef. The firing ceased on the following day, but the troubles of the people were rather increased than assuaged; murders and robberies were daily committed by the soldiery, the shops were all shut and some of the streets barricaded. While these scenes were being enacted, El-Elfee was besieging Demenhoo, and the other beys were returning towards Cairo, Khursheed having called them to his assistance.

Soon after this, a squadron under the command of the Turkish high admiral arrived in Abou-Keer Bay, with despatches confirmatory of the firmán brought by the former envoy, and authorizing Mehemet Ali to continue to discharge the functions of governor for the present. Khursheed at first refused to yield, but at length, on condition that his troops should be paid, he evacuated the citadel and embarked for Rosetta.

Mehemet Ali now possessed the title of Governor of Egypt, but beyond the walls of Cairo his authority was everywhere disputed by the beys, who were joined by the army of the siláhdár of Khursheed; and many Albanians deserted from his ranks. To replenish his empty coffers he was also compelled to levy exactions, principally from the Copts. An attempt was made to ensnare certain of the beys, who were encamped north of the metropolis. On the 17th of August 1805, the dam of the canal of Cairo was to be cut, and some chiefs of Mehemet Ali's party wrote, informing them that he would go forth early on that morning with most of his troops to witness the ceremony, inviting them to enter and seize the city, and, to deceive them, stipulating for a certain sum of money as a reward. The dam, however, was cut early in the preceding night, without any ceremony. On the following morning, these beys, with their memlooks, a very numerous body, broke open the gate of the suburb El-Hoseyneeyeh, and gained admittance into the city from the north, through the gate called Báb el-Futooh. They marched along the principal street for some distance, with kettle-drums behind each company, and were received with apparent joy by the citizens. At the mosque called the Ashrafeeyeh they separated, one party proceeding to the Azhar and the houses of certain sheykhs, and the other continuing along the main street, and through the gate called Báb Zuweyleh, where they turned up towards the citadel. Here they were fired on by some soldiers from the houses; and with this signal a terrible massacre commenced. Falling back towards their companions, they found the bye-streets closed; and in that part of the main thoroughfare called Beyn-el-Kasreyn, they were suddenly placed between two fires. Thus shut up in a narrow street, some sought refuge in the collegiate mosque El-Barkookeeyeh, while the remainder fought their way through their enemies, and escaped over the city-wall with the loss of their horses. Two memlooks had in the meantime succeeded, by great exertions, in giving the alarm to their comrades in the quarter of the Azhar, who escaped by the eastern gate called Báb el-

Ghureiyib A horrible fate awaited those who had shut themselves up in the Barkookeeyeh. Having begged for quarter and surrendered, they were immediately stripped nearly naked, and about fifty were slaughtered on the spot; and about the same number were dragged away, with every brutal aggravation of their pitiful condition, to Mehemet Ali. Among them were four beys, one of whom, driven to madness by Mehemet Ali's mockery, asked for a drink of water; his hands were untied that he might take the bottle, but he snatched a dagger from one of the soldiers and rushed at the pasha, and fell covered with wounds. The wretched captives were then chained and left in the court of the pasha's house; and on the following morning the heads of their comrades who had perished the day before were skinned and stuffed with straw before their eyes. One bey and two others paid their ransom and were released; the rest, without exception, were tortured and put to death in the course of the ensuing night. Eighty-three heads (many of them those of Frenchmen and Albanians) were stuffed and sent to Constantinople, with a boast that the Memlook chiefs were utterly destroyed. Thus ended Mehemet Ali's first massacre of his too confiding enemies.

The beys, after this, appear to have despaired of regaining their ascendancy, most of them retreated to Upper Egypt, and an attempt at compromise failed. El-Elfee offered his submission on the condition of the cession of the Feiyoom and other provinces; but this was refused, and that chief gained two successive victories over the pasha's troops, many of whom deserted to him.

At length, in consequence of the remonstrances of the English, and a promise made by El-Elfee of 1500 purses, the Porte consented to reinstate the twenty-four beys, and to place El-Elfee at their head; but this measure met with the opposition of Mehemet Ali and the determined resistance of the majority of the Memlooks, who, rather than have El-Elfee at their head, preferred their present condition; for the enmity of El-Bardeesee had not subsided, and he commanded the voice of most of the other beys. In pursuance of the above plan, a squadron under Sâlih Pasha, shortly before appointed high admiral, arrived at Alexandria on the 1st of July 1806, with 3000 regular troops, and a successor to Mehemet Ali, who was to receive the pashalik of Salonica. This wily chief professed his willingness to obey the commands of the Porte, but stated that his troops, to whom he owed a vast sum of money, opposed his departure. He induced the 'Ulemâ to sign a letter, praying the sultan to revoke the command for reinstating the beys, persuaded the chiefs of the Albanian troops to swear allegiance to him, and sent 2000 purses contributed by them to Constantinople. El-Elfee was at that time besieging Demenhor, and he gained a signal victory over the pasha's troops; but the dissensions of the beys destroyed their last chance of a return to power. El-Elfee and his partisans were unable to pay the sum promised to the Porte; Sâlih Pasha received plenipotentiary powers from Constantinople, in consequence of the letter from the 'Ulemâ; and, on the condition of Mehemet Ali's paying 4000 purses to the Porte, it was decided that he should continue in his post, and the reinstatement of the beys was abandoned. Fortune continued to favour the pasha. In the following month, El-Bardeesee died, aged forty-eight years; and soon after, a scarcity of provisions excited the troops of El-Elfee to revolt. That bey very reluctantly raised the siege of Demenhor, being in daily expectation of the arrival of an English army; and at the village of Shubra-ment he was attacked by a sudden illness, and died on the 30th of January 1807, at the age of fifty-five. Thus was the pasha relieved of his two most formidable enemies; and shortly after he defeated Shâheen Bey, with the loss to the latter

of his artillery and baggage and 300 men killed or taken prisoners.

On the 17th of March 1807, a British fleet appeared off Alexandria, having on board nearly 5000 troops, under the command of General Fraser; and the place, being disaffected towards Mehemet Ali, opened its gates to them. Here they first heard of the death of El-Elfee, upon whose co-operation they had founded their chief hopes of success; and they immediately despatched messengers to his successor and to the other beys inviting them to Alexandria. The British resident, Major Misset, having represented the importance of taking Rosetta and Er-Ralmânceeyeh, to secure supplies for Alexandria, General Fraser, with the concurrence of the admiral, Sir John Duckworth, detached the 31st regiment and the Chasseurs Britanniques, under Major-General Wauchope and Brigadier-General Meade, on this service; and these troops entered Rosetta without encountering any opposition; but as soon as they had dispersed among the narrow streets, the garrison opened a deadly fire on them from the latticed windows and the roofs of the houses. They effected a retreat on Abou-Keer and Alexandria, after a very heavy loss of 185 killed and 262 wounded, General Wauchope and three officers being among the former, and General Meade and seventeen officers among the latter. The heads of the slain were fixed on stakes on each side of the road crossing the Ezbekeeyeh in Cairo.

Mehemet Ali, meanwhile, was conducting an expedition against the beys in Upper Egypt, and he had defeated them near Asyoot, when he heard of the arrival of the British. In great alarm lest the beys should join them, especially as they were far north of his position, he immediately sent messengers to his rivals, promising to comply with all their demands, if they should join in expelling the invaders; and this proposal being agreed to, both armies marched towards Cairo on opposite sides of the river.

To return to the unfortunate British expedition. The possession of Rosetta being deemed indispensable, Brigadier-General Stewart and Colonel Oswald were despatched thither, with 2500 men. For thirteen days a cannonade of the town was continued without effect; and on the 20th of April, news having come in from the advanced guard at El-Hamâd of large reinforcements to the besieged, General Stewart was compelled to retreat; and a dragoon was despatched to Major Macleod, commanding at El Hamâd, with orders to fall back. The messenger, however, was unable to penetrate to the spot; and the advanced guard, consisting of a detachment of the 71st, two companies of the 78th, one of the 35th, and De Rolles's regiment, with a piequet of dragoons, the whole mustering 733 men, was surrounded, and, after a gallant resistance, the survivors, who had expended all their ammunition, became prisoners of war. General Stewart regained Alexandria with the remainder of his force, having lost, in killed, wounded, and missing, nearly 900 men. Some hundreds of British heads were now exposed on stakes in Cairo, and the prisoners were marched between these mutilated remains of their countrymen.

The beys became divided in their wishes, one party being desirous of co-operating with the British, the other with the pasha. These delays proved ruinous to their cause; and General Fraser, despairing of their assistance, evacuated Alexandria on the 14th of September. From that date to the spring of 1811, the beys from time to time relinquished certain of their demands; the pasha on his part granted them what before had been withheld; the province of the Feiyoom, and part of those of El-Geezeh and Bence Suweyf, were ceded to Shâheen; and a great portion of the Sa'eed, on the condition of paying the land-tax, to the others. Many of them took up their abode in

Cairo, but tranquillity was not secured; several times they met the pasha's forces in battle, and once gained a signal victory. Early in the year 1811, the preparations for an expedition against the Wahhábées in Arabia being complete, all the Memlook beys then in Cairo were invited to the ceremony of investing Mehemet Ali's favourite son, Toosoon, with a pelisse and the command of the army. As on the former occasion, the unfortunate Memlooks fell into the snare. On the 1st of March, Sháheen Bey and the other chiefs (one only excepted) repaired with their retinues to the citadel, and were courteously received by the pasha. Having taken coffee, they formed in procession, and, preceded and followed by the pasha's troops, slowly descended the steep and narrow road leading to the great gate of the citadel; but as soon as the Memlooks arrived at the gate it was suddenly closed before them. The last of those who made their exit before the gate was shut were Albanians under Sálíb Koosh. To these troops their chief now made known the pasha's orders to massacre all the Memlooks within the citadel, therefore, having returned by another way, they gained the summits of the walls and houses that hem in the road in which the Memlooks were incarcerated, and some stationed themselves upon the eminences of the rock through which that road is partly cut. Thus secretly placed, they commenced a heavy fire on their defenceless victims, and immediately the troops who closed the procession, and who had the advantage of higher ground, followed their example. Of the betrayed chiefs, many were laid low in a few moments; some, dismounting, and throwing off their outer robes, vainly sought, sword in hand, to return, and escape by some other gate. The few who regained the summit of the citadel experienced the same cruel fate as the rest (for those whom the Albanian soldiers made prisoners met with no mercy from their chiefs or from Mehemet Ali), but it soon became impossible for any to retrace their steps even so far; the road was obstructed by the bleeding bodies of the slain Memlooks, and their richly caparisoned horses, and their grooms. 470 Memlooks entered the citadel; and of these very few, if any, escaped. One of these is said to have been a bey. According to some, he leapt his horse from the ramparts, and alighted uninjured, though the horse was killed by the fall; others say that he was prevented from joining his comrades, and discovered the treachery while waiting without the gate. He fled and made his way to Syria. This massacre was the signal for an indiscriminate slaughter of the Memlooks throughout Egypt, orders to this effect being transmitted to every governor; and in Cairo itself, the houses of the beys were given over to the soldiery, who slaughtered all their adherents, treated their women in the most shameless manner, and sacked their dwellings. During the two following days, the pasha and his son Toosoon rode about the streets, and endeavoured to stop these atrocious proceedings, but order was not restored until 500 houses had been completely pillaged. In extenuation of this dark blot on Mehemet Ali's character, it has been urged that he had received the order for the destruction of the Memlooks from Constantinople, whither the heads of the beys were sent. It may be answered to this plea, that on other occasions he scrupled not to defy the Porte.

A remnant of the Memlooks fled to Nubia, and a tranquillity was restored to Egypt to which it had long been unaccustomed, and which has rarely been interrupted since. In the year following the massacre, the unfortunate exiles were attacked by Ibrahim Pasha, the eldest son of Mehemet Ali, in the fortified town of Ibream, in Nubia. Here the want of provisions forced them to evacuate the place; a few who surrendered were beheaded, and the rest went further south and built the town of New Dongola

(correctly Dunkulah), where the venerable Ibrahim Bey died in 1816, at the age of eighty. As their numbers thinned, they endeavoured to maintain their little power by training some hundreds of blacks; but again, on the approach of Ismail, another son of the pasha of Egypt, sent with an army to subdue Nubia and Sennár, some returned to Egypt and settled in Cairo, while the rest, amounting to about 100 persons, fled in dispersed parties to the countries adjacent to Sennár.

Mehemet Ali, being undisputed master of Egypt, at the reiterated commands of the Porte despatched in 1811 an army of 8000 men, including 2000 horse, under the command of Toosoon Pasha, against the Wahhábées. After a successful advance, this force met with a serious repulse at the pass of Safrá and Jndeyideh, and retreated to Yembo'. In the following year Toosoon, having received reinforcements, again assumed the offensive, and captured Medinah after a prolonged siege. He next took Jiddeli and Mecca, defeating the Wahhábées beyond the latter place and capturing their general. But some mishaps followed, and Mehemet Ali, who had determined to conduct the war in person, left Egypt for that purpose in the summer of 1813. In Arabia he encountered serious obstacles from the nature of the country and the harassing mode of warfare adopted by his adversaries. His arms met with various fortune; but on the whole his forces proved superior to those of the enemy. He led a successful expedition in the Hijáz, and, after concluding a treaty with the Wahhábee chief, 'Abd-Allah, in 1815, he returned to Egypt on hearing of the escape of Napoleon from Elba.

He now confiscated the lands belonging to private individuals, merely allowing them a pension for life, and attempted to introduce the European system of military tactics. A formidable mutiny, however, broke out in the metropolis, the pasha's life was endangered, and he sought refuge by night in the citadel, while the soldiery committed many acts of plunder. The revolt was reduced by presents to the chiefs of the insurgents, and Mehemet Ali very honourably ordered that the sufferers by the late disturbances should receive compensation from the treasury. The project of the "Nizám Gedeed," as the European system is called in Egypt, was, in consequence of this commotion, abandoned for a time.

Soon after Toosoon returned to Egypt, but Mehemet Ali, dissatisfied with the treaty which had been concluded with the Wahhábées, and with the non-fulfilment of certain of its clauses, determined to send another army to Arabia, and to include in it the soldiers who had recently proved unruly. This expedition, under Ibrahim Pasha, left in the autumn of 1816. After several unimportant advantages, Ibrahim sat down before the town of Er-Rass; but three months' exertions proving unavailing, he raised the siege, with the loss of nearly half his army. Notwithstanding, he advanced on the capital, Ed-Dir'eeyeh, by slow but sure steps. The last place before reaching that city offered a brave resistance, and Ibrahim, in revenge, caused all its inhabitants to be put to the sword, except a number of women and children, the former of whom were spared not from motives of pity. Ed-Dir'eeyeh fell after a five months' siege, in the course of which an explosion destroyed the whole of the besiegers' powder; and had the Wahhábées been aware of the extent of the disaster, few, we may believe, would have escaped to tell the tale. 'Abd-Allah, their chief, was taken, and with his treasurer and secretary was sent to Constantinople, where, in spite of Ibrahim's promise of safety, and of Mehemet Ali's intercession in their favour, they were paraded and put to death. At the close of the year 1819, Ibrahim returned to Cairo, having conquered all present opposition in Arabia, but without having broken the spirit of the Wahhábées.

The pasha, since his return from Arabia, had turned his attention to the improvement of the manufactures of Egypt, and engaged very largely in commerce. The results of these attempts are stated in other places, but the important work of digging the new canal of Alexandria, called the Mahmoodeech, must here be again mentioned. The old canal had long fallen into decay, and the necessity of a safe channel between Alexandria and the Nile was much felt. Such was the object of the canal then excavated, and it has on the whole well answered its purpose; but the sacrifice of life was enormous, and the labour of the unhappy felláhs was forced. Towards the accomplishment of a favourite project, the formation of the Nizám Gedeed, a force was ordered to the southern frontier of Egypt, and the conquest of Sennár was contemplated in order to get rid of the disaffected troops, and to obtain a sufficient number of captives to form the nucleus of the new army. The forces destined for this service were led by Ismail, then the youngest son of Mehemet Ali; they consisted of between 4000 and 5000 men, Turks and Arabs, and were despatched in the summer of 1820. Nubia at once submitted, the Shágeeyeb Arabs immediately beyond the province of Dongola were worsted, and Sennár was reduced without a battle. Mohammad Bey, the defterdár, with another force of about the same strength, was then sent by Mehemet Ali against Kurdufán with a like result, but not without a hard fought engagement. In 1822 Ismail was, with his retinue, put to death by an Arab chieftain named Nimr; and the defterdár, a man infamous for his cruelty, assumed the command in those provinces, and exacted terrible retribution from the innocent inhabitants.

In the years 1821 and 1822 Mehemet Ali despatched both ships and men (the latter about 7000 or 8000 Albanians and Turks) to the Morea, Cyprus, and Candia, to aid the Porte in reducing the Greek insurrection; and he continued to take part in that struggle, his fleet being engaged at Navarino, until the English insisted on the evacuation of the Morea in 1828 by Ibrahim Pasha. In 1822 an army of disciplined troops was at length organized: 8000 men (chiefly slaves, from Sennár, and Kurdufán) were trained by French officers at Aswán. Of the vast numbers seized in the countries above named, many died on the way; those who were not eligible were, with the women, sold in Cairo, and in the remainder were incorporated many felláhs. Colonel Sèves (Snleymán Pasha), a Frenchman who afterwards became a Moslem, superintended their organization; great numbers of the blacks died, but the Egyptians proved very good troops. Many thousands were pressed in consequence, and they now constitute the bulk of the army. In 1823 the new conscripts amounted to 24,000 men, composing six regiments of infantry, each regiment consisting of five battalions of 800 men, and the battalions of eight companies of 100 men.

In 1824 a native rebellion of a religious character broke out in Upper Egypt, headed by one Ahmad, an inhabitant of Es-Sálmeech, a village situate a few miles above Thebes. He proclaimed himself a prophet, and was soon followed by between 20,000 and 30,000 insurgents, mostly peasants, but some deserters from the Nizám, for that force was yet in a half-organized state and in part declared for the impostor. The insurrection was crushed by Mehemet Ali, and about one-fourth of Ahmad's followers perished, but he himself escaped and was never after heard of. Few of these unfortunates possessed any other weapon than the long staff (nebbot) of the Egyptian peasant; still they offered an obstinate resistance, and the combat resembled a massacre. In the same year war was once more made on the Wahhábees, who had collected in considerable numbers. The 2d regiment was sent on this service, and it behaved in a very creditable manner.

But the events of the war with the Porte are perhaps the most important of the life of Mehemet Ali. The campaign of 1831 had ostensibly for its object the castigation of 'Abd-Allah, pasha of Acre; the invading force consisted of six regiments of infantry, four of cavalry, four field-pieces, and a greater number of siege-guns, the whole under the command of Ibrahim Pasha, while the fleet, conveying provisions, ammunition, &c., was to accompany the army by sea. The terrible cholera of 1831, however, stayed the expedition when it was on the eve of departing; 5000 of its number died, and it was not until early in October of the same year that it started. Little opposition was encountered on the way to Acre, whither Ibrahim had gone by sea, and that place was invested on the 29th of November. The artillery of the besieged was well served; an assault in the following February was repulsed, and the cold and rain of a Syrian winter severely tried the Egyptian troops. A second assault in like manner failed, and Ibrahim was called away to repel 'Osmán Pasha, governor of Aleppo. The latter, however, hastily decamped without giving him battle, and Ibrahim, deeming this advantage sufficient, retraced his steps towards Acre. He then pushed the siege with fresh vigour, and stormed the city on the 27th of May; 1400 men fell in the breach, and the garrison was found to be reduced to about 400 men. The fall of Acre was followed by negotiation. Mehemet Ali evinced a disposition for peace, but demanded the government of Syria, and the Porte, in consequence, denounced him as a traitor. On his part, Ibrahim pushed his successes; Damascus was evacuated at his approach, and the battle of Hms, fought on the 8th of July 1832, decided the superiority of the Egyptian army, and the advantage of disciplined troops over an irregular force, although very disproportionate in numbers. The enemy composed the advanced guard of the Turkish army, 30,000 strong, and the Egyptians numbered only 16,000 men.

After this victory, Ibrahim marched to Hamáh, and thence to Aleppo (which had just before closed its gates against the Turkish general-in-chief, Hoseyn Pasha, whose troops became rapidly disorganized), forced the defiles of Beylán, and pursued the fugitive Turks to Adaneh. About the same time an Egyptian squadron had chased the sultan's fleet into Constantinople. Diplomacy was, at this point, again resorted to, but without any result; the sultan depended on his fleet to protect the capital, and determined to risk another engagement with the victorious enemy. The charge of this venture was intrusted to Resheed Pasha, the grand vizir. In the meantime, Ibrahim Pasha had gained the pass of Taurus, and having beaten the Turks at Oulun-Kislák, he hesitated not to give battle to Resheed Pasha at the head of about 60,000 men, his own army being less than half that strength; the battle of Koomech, on the plains of Anatolia, proved utterly disastrous to the Porte; in the confusion of the fight, and the darkness of a thick day, the grand vizir was made prisoner, his army routed, and Constantinople was within six marches of the victor, without an army to oppose his passage. The capital of the Ottoman Empire, in imminent danger by sea and land, was then intrusted to the keeping of its hereditary enemy, as the last resource of the sultan Mahmood, and a Russian fleet and army were sent thither. Negotiations were in consequence opened, and on the 14th of May 1833 a treaty was concluded between Mehemet Ali and the Porte, by which the whole of Syria and the district of Adaneh were ceded to the former, on condition of his paying tribute. With this terminated the war, but not the amosity of the sultan. Ibrahim, by excessive firmness and rigour, speedily restored security and tranquillity to the greater part of Syria; but some years later, the attempt of Mahmood to get the better of his vassal, and the consequent

disaster experienced by his arms at Nezeeb, entailed fresh complications, and the interference of Great Britain ended in the restoration of Syria to the Porte in 1841. Mehemet Ali had placed all his reliance on the co-operation of France, and to its desertion of his cause, and his confidence in its assistance, either moral or material, must be ascribed the unfortunate issue of the war. That the Syrians, in general, preferred the rule of Mehemet Ali to the tyranny of pashas appointed from Constantinople may be safely averred, but we cannot close this account of his possession of that province without animadverting on the horrible cruelties perpetrated by Ibrahim Pasha, or warning our readers not to give credence to the unmeasured praise bestowed by many on the Egyptian troops there engaged. Conceding that they were superior soldiers to the Turks, it must be borne in mind that they were veterans, disciplined and led by the French officers and an able general; their opponents were destitute of any European discipline, badly officered, and discouraged by the disasters in Greece. It has, moreover, been stated on good authority, that Ibrahim owed much of his success to the placing of artillery in the rear of his troops, with orders to fire on them should they show symptoms of wavering.

After the peace of 1841 Mehemet Ali gave up all great political projects, and solely occupied himself in improvements, real or imaginary, in Egypt. He continued to prosecute his commercial speculations, and manufacturing, educational, and other schemes. The barrage of the Nile, still uncompleted, was commenced by his direction, and in 1847 he visited Constantinople, where he received the rank of vizir. In the year 1848, however, symptoms of imbecility appeared; and after a short space Ibrahim was declared his successor, but died after a brief reign of two months.

Mehemet Ali survived Ibrahim, and died on the 3d of August 1849. Many and conflicting have been the opinions entertained of this remarkable man, for such at least all acknowledge him to have been. His massacre of the Memlooks has been the great point of attack by his enemies, but that, as well as many of his other acts, must be ascribed to his boundless ambition, not to innate cruelty, for he proved himself to be averse to unnecessary bloodshed. That he really esteemed European civilization may be doubted; but his intelligent mind could not fail to perceive that therein lay his great strength, and of this he availed himself with consummate ability. To his firm government Egypt is indebted for the profound tranquillity which it has long been its good fortune to enjoy. A traveller of any nation or faith may traverse it in its length and breadth with greater safety than almost any other country out of Western Europe, and the display of fanaticism has been rigorously punished. While, however, Egypt has benefited by the establishment of order, the people have suffered most severe exactions. The confiscation of private lands has been before mentioned; to that arbitrary act must be added the seizure of the lands of the mosques, the imposition of heavy taxation, and a system of merciless impressment. In fact, the condition of the Egyptian fellâh has rarely been as wretched as it is at the present day. Mehemet Ali also misunderstood the real resources of Egypt, which are certainly agricultural, he dealt a severe blow to native produce by endeavouring to encourage manufacturing industry, and by establishing enormous Government monopolies, a measure which crushed the spirit of the agriculturists. His military and governing abilities were assuredly very great, and his career is almost unequalled in Turkish history. Had it not been for the intervention of Great Britain, his Syrian successes over the Porte would probably have rescued Egypt from the wretched condition of a Turkish

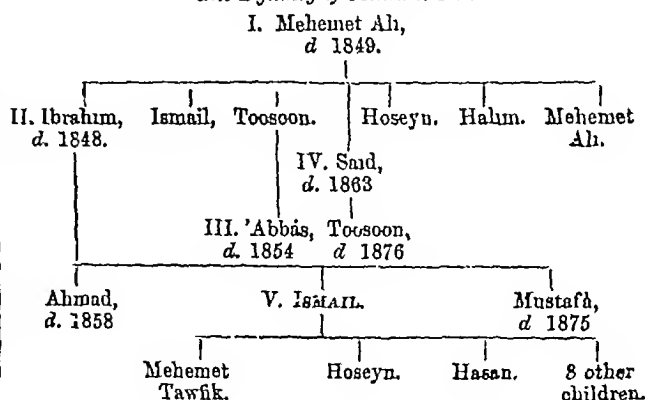

province. But the firmân of 1841 entailed the loss of all his military power, the army was reduced to 18,000 men, and the navy condemned to rot in the harbour of Alexandria; while Mehemet Ali, failing to gain the great object of his ambition, the establishment of an independent dynasty, and being compelled to look on his then living family as his only heirs, thenceforth confined himself to measures of less importance, and did not prosecute even these with his former energy.

The entire constitution of the government of Egypt is the work of Mehemet Ali. With a few exceptions, he destroyed all former usages, and introduced a system partly derived from European models. The army and navy are of his creation, so are the taxation, the regulation of import and export duties, &c., quarantine laws, the manufactories, colleges, and the ministry. Some of these institutions are useful, others both vexatious and ill-calculated for the country. The colleges of languages and medicine, and the printing-press at Bôulâk, are among the former, and are exceedingly praiseworthy efforts in a right direction; and in the same category must be placed many minor improvements, in which Mehemet Ali showed himself to be far in advance of his countrymen; while, weighing his chequered life and numerous disadvantages of position and nation, his moral character, enlightened mind, and distinguished ability must place him high among the great men of modern times.¹

Ibrahim was succeeded by his nephew 'Abbâs, son of Toosoon. This miserable voluptuary, and withal bigoted though ignorant Muslim, utterly neglected the affairs of government and solely consulted his own gratification. During his reign all the great works begun by Mehemet Ali were suspended. It was a time of deliberate retrogression, and his sudden death in July 1854 was welcomed by all true Egyptians as the removal of the country's curse. His successor, Saïd Pasha, the fourth son of Mehemet Ali, endeavoured to pursue his great father's policy and to carry out his aims. He had not, however, the strength of character or the health needed to meet the serious difficulties of the task, and he will chiefly be remembered for the abolition of some of the more grinding Government monopolies, and for the concession of the Suez Canal. It was reserved for his nephew, the present khedive, to attain all and more than all that Mehemet Ali had designed for his country.

The reign of Ismail promises to be the beginning of a new era for Egypt. A man of undoubted ability, possessed of unusual energy in administration, fully appreciative of the importance of Western civilization, fired with the ambition proper to a grandson of Mehemet Ali, the khedive is a ruler such as Egypt has scarcely seen since the Arab conquest. His first step was to remove, as far as possible, the irksome control of the Porte. At great cost he obtained an imperial firmân in 1866, removing almost all the old treaty restrictions, granting him the title of khedive

¹ *The Dynasty of Mehemet Ali.*

(pron. khedeev), and settling the succession on the eldest son; and in 1872 another firmán made him virtually an independent sovereign.

Having thus obtained for himself and his dynasty a settled regul rank, Ismail turned his attention home-wards, and began a series of reforms such as no previous governor of Egypt ever contemplated. He re-established and improved the administrative system organized by Mehemet Ali, and which had fallen into decay under 'Abbás's indolent rule; he caused a thorough remodelling of the customs system, which was in an anarchic state, to be made by English officials; in 1865 he bought the Egyptian post-office, and placed it under the direction, with full powers, of an official from St Martin's le Grand, who has brought it into admirable working order; he re-organized the military schools of his grandfather, and lent his willing support to the cause of education in every way. Public works have largely engaged the attention of the khedive. Railways, telegraphs, lighthouses, the harbour works at Suez, the breakwater at Alexandria, have been carried out under his personal auspices by some of the best contractors of Europe. If there is a fault to be found in this Europeanizing of Egypt, it is that the practical zeal for modern civilization leaves no room for the honourable respect due to the unique antiquities of the country. It is true that ancient Egypt is protected by the care of Mariette Bey, but the art of the Arabs is suffered to decay, nay, is even purposely demolished, to make room for modern French gewgaws. A recent writer tells us that a new street cuts through about a mile of the "old Arab rookeries," and gravely advances the opinion that the opera house and the public gardens and the other meretricious abominations that have been set up in Cairo are worthy of a second class European city! Still, terrible as is the vandalism now going on in Egypt, there can be little doubt that the present policy of the khedive will add greatly to the prosperity and health of the people. At the same time, future generations will gain at the fearful expense of the present. The funds required for these public works, as well as the actual labour, have been remorselessly extorted from a poverty-stricken population; and there is probably no peasant now existing whose condition is worse than that of the long-suffering Egyptian felláh.

One of the greatest reforms that Egypt owes to its present ruler is the abolition of the old system of consular jurisdiction, and the substitution of mixed courts, where European and native judges sit together to try all mixed cases without respect to nationality. These courts were established in 1876 on the suggestion of the wisest of Egypt's statesmen, Nubar Pasha, and on the recommendation of an international commission. A code based on the Mohamadan law and the Code Napoléon has been drawn up, which seems thoroughly suited to the needs of the position; and the best results may be looked for from this reform. It were greatly to be desired that the jurisdiction of these courts should be extended so as eventually to supersede the old native system. At present they only take the place of the consular courts.

In recent times the khedive has annexed a large territory to the south of Khartoom, now extending about as far as Gondokoro, and which will doubtless shortly include the lakes of Victoria and Albert Nyanza. The expedition was at first commanded by Sir Samuel Baker, with very unsatisfactory results; and great relief was felt when the continuation of the work of conquest was intrusted to Colonel Gordon, an officer in whose character and ability the fullest confidence is placed. The khedive has professed himself anxious to put down the Nile slave-trade, and that he is really desirous of seeing the traffic ended is shown by the full powers he has given Colonel Gordon for the

suppression of it in the heart of the slave-country. What the result will be it is hard to foretell; but the good faith of the khedive and the determination of Colonel Gordon are now beyond a doubt. Quite recently (Aug. 14, 1877) a convention between the British and Egyptian Governments for the suppression of the slave-trade has been signed, imposing stringent penalties on the importation of slaves into Egypt, and extending the power of search in the case of suspected vessels.

Altogether it may be believed that a better time is beginning for Egypt. (E.S.P.—S.L.P.)]

TOPOGRAPHY AND MONUMENTS.¹

The northern coast of Egypt is low and barren, presenting no features of interest, and affording no indication of the character of the country which it bounds. It is a barrier, generally of sand-hills, but sometimes of rock, for the most part wholly destitute of vegetation, except where grow a few wild and stunted date-palms. Immediately behind are desolate marshy tracts or extensive salt lakes, and beyond, the fertile country. The last is a wide plain, intersected by the two branches of the Nile, and by many canals, of which some were anciently branches of the river, and having a soil of great richness, though in this particular it is excelled by the valley above. The only inequalities of the surface are the mounds of ancient towns, and these, often if not always ancient, on which stand the modern towns and villages. The palm-trees are less numerous, and not so beautiful as in the more southern part of the country, but other trees are more common. The houses and huts of the towns and villages are of burnt brick near the Mediterranean; but as the climate becomes drier, and the occurrence of rain far less frequent, the use of crude brick obtains, until near the point of the Delta it is very general. The mosques even of the towns are rarely remarkable for architectural beauty in the tract to the north of Cairo. The palaces or villas of the Turkish grandees, which are not uncommon, have, however, a light and picturesque appearance, though their style is not good. The deserts which inclose the plain on both sides are rocky tracts of very slight elevation, having their surface overspread with sand and other debris.

Of the towns on the northern coast, the most western, Alexandria, called by the natives El-Iskendereeyeh, is the largest and the most important. It was founded in the year B.C. 332 by Alexander the Great, who gave it the form of a Macedonian mantle (chlamys). The ancient city occupied the space between the sea and Lake Marcotis, being about four miles in its greatest length, and a little less than a mile in its greatest breadth. The island of Pharos was likewise inhabited, and was joined to the continent by the mole called the Heptastadium. The Heptastadium and the island divided the bay into two harbours. These were spacious, and although the western, anciently called Portus Eunosti, but now the Old Port, is difficult to enter, and the eastern, Magnus Portus, or the New Port, is not so deep and is less secure, they are, except Port Said, by far the best anchorages on this coast of Egypt.

Alexandria, which partly occupied the site of the ancient Rhacotis, a place of little importance, naturally speedily increased in consequence, and became the emporium of the trade between Europe, Arabia, and India. After the death of Alexander the city became the capital of the Ptolemies. By the Ptolemies Alexandria was adorned with palaces and

¹ The following account of the topography and monuments of Egypt is mainly based on Mr Lane's MS. "Description of Egypt," which the writer of this article used as his guide to the monuments during his residence in that country.

of great magnificence, for which they did not scruple to despoil more ancient edifices of some of their chiefest ornaments. While its commercial importance increased, it became a celebrated seat of learning, with the greatest library of antiquity, through the wise interest with which the Greek kings regarded science and letters. Under the Ptolemies, however, the inhabitants, who were chiefly Greeks, became very troublesome to their rulers, like most commercial populations, and their turbulence was ill restrained by the weakness of the later sovereigns of that line. From the time of the Roman conquest, B.C. 30, until it was taken by the Arabs, A.D. 641, Alexandria sensibly declined, partly in consequence of its being a provincial capital, instead of a royal residence, but chiefly because of the unruly disposition of its inhabitants, and their violent religious and political disputes, which at last resulted in the seat of government being transferred to the fortress of Egyptian Babylon, near the modern Cairo, which became in some sort the capital. During this period it had been distinguished for the learning of its ecclesiastics, and the strong part which they took in the theological differences of the early church. Under the Muslims Alexandria never regained the position of metropolis of Egypt, and its importance, with some fluctuations, waned until the discovery and consequent adoption of the route to India by the Cape of Good Hope almost withdrew the main cause of its prosperity. Recently, however, the resumption of the overland route has greatly benefited this city, and although it was not made the capital, it became the favourite residence of Mehemet Ali, which in like manner contributed to its welfare.

The older part of the town of Alexandria stands upon the Heptastadium, now much wider than it was anciently; but the recent part, where are the houses of the European merchants, occupies the site of a portion of the ancient city, which was nearest to the mole. The most striking edifice is the castle on the island of Pharos, containing a lighthouse, which has succeeded to the more famous Pharos of antiquity. Here also is the pasha's palace, as well as a lesser Pharos. The houses of the town are built of stone, or have their lowest story cased with that material, and the portion above built of brick plastered and whitewashed. The residences of the European merchants and consuls and the richer Turks and natives are spacious and well-built, somewhat in the modern Italian style, but have no claims to architectural beauty. The mosques are not remarkable, but the English church will, if ever completed, be a great ornament to the town. The population of the town is estimated at over 200,000. One of the favourite projects of Mehemet Ali was the fortification of Alexandria, which has been thus rendered so strong that if well garrisoned it could not be invested by a force of less than about 40,000 men.

The ancient remains are very scanty and of little interest, compared to those which are seen on the sites of other Egyptian towns. Two objects are conspicuous, one of the obelisks commonly called "Cleopatra's Needles," and the great column known as "Pompey's Pillar." The former is a fine obelisk of red granite nearly 70 feet in height, bearing hieroglyphic inscriptions with the names of Thothmes III., Ramses II., and a later king. Beside it was a fallen obelisk of the same dimensions, its fellow, now (Oct 1877) on its way to England. They were brought here from some ancient temple during the Roman rule. Pompey's Pillar is in like manner of red granite, and its shaft is about 70 feet high, the whole column being nearly 100 feet in height. Its pedestal bears a Greek inscription in honour of the emperor Diocletian.

Proceeding to the east of Alexandria, the first place of importance is Er-Rasheed, called by the Europeans Rosetta,

a considerable town on the west bank of the Rosetta branch of the Nile, anciently the Bolbitine. Before the cutting by Mehemet Ali of the Mahmoodeech Canal to connect Alexandria with this branch of the river, Rosetta was a place of greater importance than now, as in consequence of the decay of the old canal of Alexandria, the overland trade from India chiefly passed through it. It is a well-built town, having some gardens, and is in many respects more agreeable than Alexandria. Its population is stated to be 15,000. A little to the north of the town is the boghâz, a bar of sand stretching across the mouth of the river, and rendering it often impassable; and between it and Rosetta is an old fort called Fort St Julien by the French, who repaired it during their occupation of Egypt, when one of their officers discovered the Rosetta Stone, the famous trilingual tablet which afforded the clue by which hieroglyphics were interpreted.

In ascending the Rosetta branch, the first place of interest is the site of Sais, *Sai*, on the eastern bank, marked by lofty mounds, and the remains of massive walls of crude brick, which were those of a great inclosure in which the chief temple and doubtless other sacred edifices stood. The goddess Nit or Neith was the divinity of the place, and a great festival was annually held here in her honour, to which pilgrims resorted from other parts of Egypt. Sais was remarkable for the learning of its priests, and was the royal residence of the Saitic kings (Dynasties XXIV., XXVI.) A modern village here is called "Sâ-el-Hagar," or "Sais of the Stone," a name which perhaps alludes to the famous monolith described by Herodotus.

In the interior of the modern Delta no remains of importance have been discovered, though there are many ancient sites marked by mounds. The chief towns are El-Mahallah el-Kebereh, not far from the Damietta branch, about forty miles from the sea; Tanta, nearly in the middle of the Delta; and Manoof, farther south. Of these Tanta is best known as the birth-place of a Muslim saint, the sayyid Ahmad El-Bedawee, in whose honour three festivals are annually kept, the greatest of which attracts more pilgrims than any other in Egypt, and is in this respect second alone to the pilgrimage to Mecca. The festivals of Tanta are rather distinguished by riot than piety, and recall the revelries of Bubastis and Canopus.

Several places of interest are found on the course of the Damietta branch, the old Phatnitic or Pathmetie. First of these is the town whence it takes its name, Dimyat, called by the Europeans Damietta, which stands not far from the mouth of the branch, on its eastern side. In the time of the crusades it was a strong place, and regarded as the key of Egypt. It was taken and retaken by the contending forces, and formed the basis of the operations of St Louis in the unfortunate eighth crusade. Shortly afterwards the sultan Edh-Dhâhir Beybars, in A.D. 1251, razed it and rebuilt it on the present site somewhat farther from the sea. It is a flourishing town, and has a population of 29,000 inhabitants. The next place of importance is the town of El-Mansoorah, founded by El-Melik El-Kâmil, the nephew of Saladin, during the sixth crusade, to commemorate, as its name imports, his success over the invading army of Jean de Brienne. A little to the south of El-Mansoorah, on the opposite or western bank, at a short distance from the river, are the remains of a very remarkable temple of the goddess Isis, and the mounds of the town of Iseum. Although the temple is entirely thrown down, as though by a natural convulsion, but probably by human violence, its plan may be partly traced and its date ascertained, as the materials have not been removed. It was, unlike most Egyptian temples, built altogether of granite, and was about 600 feet in length and 200 in breadth. The materials must have been transported

from Syene, a distance by the river, on which they were doubtless floated, of more than 600 miles. Bearing in mind this circumstance, and the difficulty of both working and sculpturing so hard a material, this temple must be considered to be one of the most costly in the country. The earliest name which has been found here is that of Nekht-har-heb (Dynasty XXX.), but the most common one is that of Ptolemy Philadelphus. A little to the south of this site, on the same bank, is the small town of Semennood, auciently Sebennytus; and a short distance farther, on the same side, is the village of Abou-Seer, the ancient Busiris named after Osiris, who, with Isis, was here worshipped. Herodotus mentions among the great festivals that of Isis held at Busiris, but this was more probably kept at Iseum, which was not far. For a long distance there is nothing of interest until we reach Tel-Atreeb, where the site of the town of Athribis is marked by high mounds, with remains of ancient houses and some blocks of stone.

To the eastward of the Damietta branch, in the broad cultivated tract or the desert beyond, are some places worthy of note. The most eastern of these is the site of Pelusium, which was, in the times of the Pharaohs of Dynasty XXVI., the key of Egypt towards Palestine. No important remains have been discovered here. Between this site and the Damietta branch are the mounds of Tanis, or Zoan, Z'AN, ZAR, where are considerable remains of the great temple, the most remarkable of which are several fallen obelisks, some of which are broken. From their inscriptions, and those of other blocks, it has been ascertained that the temple was as ancient as the time of Dynasty XII., and was much beautified by Ramses II. and other kings of that time and the subsequent period. Tanis was on the eastern bank of the Tanitic branch of the Nile, now called the Canal of the El-Mo'izz. On the same side of the same branch, but far to the south, was the city of Bubastis, PE-BAST, the site of which is indicated by very lofty mounds, in which may be traced the remains of its great temple, which was entirely of red granite. Here was held the festival of the goddess Bast, or Bubastis, which attracted great crowds of pilgrims, and is ranked by Herodotus first of the festivals of Egypt. Not far south, and on the borders of the desert, is Bilbeys, which was a place of some importance as a frontier-town in the time of the Eiyoohee princes. Still farther south are the mounds of Onion, the Jewish city founded by the high priest Onias, where was a temple closed by Vespasian not long after the overthrow of Jerusalem. The site is called Tell-el-Yahoodceyeh, or "The Mound of the Jewess."

At the point of the Delta is the unfinished barrage, which, by crossing both branches of the river, will regulate the innndation above and below this point. The river here becomes broader than in its divided state, and long continues so. A little south of the point of the Delta, on the eastern bank of the river, near the village of El-Matareeyeh, not far north of Cairo, is the site of the ancient Heliopolis, or On, AN, the City of the Sun, marked by a solitary obelisk, and crude brick ridges formed by the ruins of a massive wall. The obelisk bears the name of Usurtesen I., the second king of Dynasty XII., in the simple inscription which runs down each of its sides. It is of red granite, and nearly 70 feet in height. The city was famous rather for the learning of its college than for its size, and the temple of the sun was held in high veneration. Many famous Greek philosophers studied here, and much of their earliest knowledge of natural science was no doubt derived from their Egyptian instructors.

Boolák, the port of Cairo, is a flourishing town, having two remarkable mosques. It was built A.H. 713, in the reign of the sultan Mohammad Ibn Kaláoon. Here M.

Mariette has founded the national "Musée Boulaq," a splendid collection of Egyptian antiquities.

Cairo is the fourth Muslim capital of Egypt; the site of one of those that have preceded it is, for the most part, included within its walls, while the other two were a little to the south. 'Amr, the Muslim conqueror of the country, founded El-Fustát, the oldest of these, close to the fortress of Egyptian Babylon, the seat of government at that time. Its name signifies "the Tent," as it was built where 'Amr had pitched his tent. The new town speedily became a place of importance, and was the residence of the Náibs, or lieutenants, appointed by the orthodox and Ommiade caliphs. It received the name of Masr, properly Misr, which was also applied by the Arabs to Memphis and to Cairo. It declined after the foundation of El-Káhíreh, but never became altogether deserted, for a small town, called Masr El-'Ateekah, or "Old Masr," occupies, in the present day, part of what was its area in its time of prosperity. Shortly after the overthrow of the Ommiade Dynasty, and the establishment of the 'Abbásee, the city of El-'Askar was founded (A.H. 133) by Suleymán, the general who subjugated the country, and became the capital and the residence of the successive lieutenants of the 'Abbásee caliphs. El-'Askar was a small town adjacent to El-Fustát, of which it was a kind of suburb. Its site is now entirely desolate. The third capital, El-Katáé', or El-Katáyé', was founded about A.H. 260, by Ahmad Ibn-Tooloou, as his capital. It continued the royal residence of his successors; but not long after the fall of the dynasty, and the subsequent Ikhsheedees, the seat of government was transferred by the Fátímees to a new city, El-Káhíreh. El-Katáé', which had been sacked on the overthrow of the Tooloonees, rapidly decayed. A part of the present Cairo occupies its site, and contains its great mosque, that of Ahmad Ibn-Tooloou.

Góhar el-Káid, the conqueror of Egypt for the Fatimee caliph El-Mo'izz, founded a new capital, A.H. 358, which was named El-Kahireh, that is, "the Victorious," a name corrupted into Cairo. This town occupied about a fourth part, the north-eastern, of the present metropolis. By degrees it became greater than El-Fustát, and took from it the name of Misr, or Masr, which is applied to it by the modern Egyptians. It continually increased, so as to include the site of El-Katáé' to the south, and of the old town of El-Maks to the west. The famous Saladin built the Citadel on the lowest point of the mountain to the east, which immediately overlooked El-Katáé', and he partly walled round the towns and large gardens within the space now called Cairo. Under the prosperous rule of the Memlook sultans this great tract was filled with habitations; a large suburb to the north, the Hoseyneeyeh, was added; and the town of Boolák was founded. After the Turkish conquest (A.D. 1517) the metropolis decayed, but its limits were the same; with the present dynasty it has somewhat recovered.

Cairo is of an irregular oblong form. Its greatest length is about three miles, and its average breadth about a mile and a half, and its dimensions do not fall very much short of these in any part. M. Jacotin (*Description de l'Égypte*, xviii. p. 111) estimates the superficies of Cairo at 793 hectares, or about 3 square miles. This surface is not, however, entirely occupied by houses, for it contains the Citadel and various extensive gardens and open spaces, as well as lakes. Most of the streets are extremely narrow, and the markets generally crowded, so that the stranger usually acquires a delusive idea of the density of the population. Mr Lane states the population to have been 240,000 before the great plague of 1835, and adds that the deficiency, equal to not less than one-third of the inhabitants, caused by that terrible visitation, would be speedily supplied from the villages. (*Modern Egyptians*, Introd.

tion.) Sir Gardner Wilkinson, in his *Modern Egypt and Thebes* (i. 256), published in 1843, gives the population at about 200,000; and Mrs Poole, writing in 1842, estimates it at about 240,000 (*Englishwoman in Egypt*, i. 136); but Clot-Bey (*Aperçu Général*, i. 204), whose work appeared in 1840, states the much higher amount of about 300,000 souls. The census of 1847-8 states the more moderate number of 253,541 inhabitants, and in this instance it is not likely to have been far wrong. We may fairly suppose that during the time of comparative prosperity that followed the great plague of 1835, the population gradually increased to about 250,000, and that the cholera in 1848, and the conscriptions occasioned by the Crimean War, somewhat diminished its amount, which in the subsequent time of peace rose to the present sum of about 350,000. Of the population of 240,000, in Mr Lane's estimate, about 190,000 were Muslim Egyptians, about 10,000 Copts, 3000 or 4000 Jews, and the rest, strangers from various countries. The adult male population was about one-third of the whole, or 80,000 persons, of whom 30,000 were merchants, petty shopkeepers, and artisans, 20,000 domestic servants, and 15,000 common labourers, porters, &c.; the remainder chiefly consisting of military and civil servants of the Government (*Modern Egyptians*, l. c.).

Cairo is still the most remarkable and characteristic of Arab cities. The beauty of its religious and domestic architecture, before the recent innovations, is unexcelled elsewhere. The edifices raised by the Moorish kings of Spain and the Muslim rulers of India may have been more splendid in their materials, and more elaborate in their details, the houses of the great men of Damascus may be more costly than were those of the Memlook beys; but for purity of taste and elegance of design both are far excelled by many of the mosques and houses of Cairo. These mosques have suffered much in the beauty of their appearance from the effects of time and neglect; but their colour has been often thus softened, and their outlines rendered the more picturesque. What is most to be admired in their style of architecture is its extraordinary freedom from restraint, shown in the wonderful variety of its forms, and the skill in design which has made the most intricate details to harmonize with grand outlines. Here the student may best learn the history of Arab art. Like its contemporary Gothic, it has three great periods, those of growth, maturity, and decline. Of the first, the mosque of Ahmad Ibn-Tooloon in the southern part of Cairo, and the three great gates of El-Káhíreh (the old city), the Bab-en-Nasr, Bab-el-Futooh, and Bab-Zuweyleh, are splendid examples. The leading forms are simple and massive, with in the mosque horse-shoe arches. The decoration is in friezes, and its details of conventionalized foliage. The second period passes from the highest point to which this art attained to a luxuriance promising decay. The mosque of Sultan Hasan, below the Citadel, those of Mneiyad and Kalá-oon, with the Barkookeiyeh, in the main street of the old city, and the mosque of Barkook in the Cemetery of Káit Bey, are instances of the earlier and best style of this period. The forms, though still massive, are less simple, and they are admirably adapted to the necessities of space. The decoration is in conventionalized foliage of the most free forms, balanced by exquisite geometrical patterns. Of the last style of this period, the Ghooreeyeh, in the main street of the old city, and the mosque of Káit Bey in his cemetery, are beautiful specimens. They show an elongation of forms and an excess of decoration in which the florid qualities predominate. Of the age of decline the finest monument is the mosque of Mohammad Bey Abou-Dahab, in the old city. The forms are now poor, though not lacking in grandeur, and the details are not as well adjusted as before, with a want of mastery of the most suitable

decoration. The usual plan of a congregational mosque is a large, square, open court, surrounded by colonnades, of which the chief, often with more rows of columns, faces Mecca (eastward), and has inside its outer wall a decorated niche to mark the direction of prayer. In the centre is a fountain for ablutions, often surmounted by a dome, and in the eastern colonnade a pulpit and a desk for readers. When a mosque is also the founder's tomb, it has a richly ornamented sepulchral chamber. Of domestic architecture there are a few precious fragments before the age of decline; but most specimens are of the latest period of that age. These are marked by a singular fitness and great elegance in the interiors. The decoration, though inferior to that of the mosques of the best style, is charming for variety and beauty of pattern. See CAIRO, and also ARCHITECTURE, vol. ii. pp. 445-44.

To the east of Cairo is a bold spur of the mountains known as El-Gebel El-Mukattam. Beneath it, and to the north of the Citadel, is the Cemetery of Káit Bey, remarkable for the splendid tombs of the Memlook sultans. The most beautiful of these is that of Káit Bey, from which the cemetery takes its name, but those of the sultan Barkook and of El-Ghooree must not be passed by unmentioned. At a little distance to the north-east is the Gebel-el-Ahmar, or "Red Mountain," and southward of this, petrified wood in large quantities is seen strewn on the surface of the desert. The space between Cairo and the Nile, varying from a mile to a mile and a half in breadth, is occupied by plantations which were made by Ibrahim Pasha during his father's rule. Formerly this side of the city was, as the other three are still partially, bounded by lofty mounds of rubbish; these he caused to be removed, and by doing so conferred a great benefit upon the inhabitants, as well as by planting with trees the intervening space. By irrigating this tract very freely with a steam-engine he considerably lessened the good he had effected, rendering the western part of the city somewhat damp. To the south of Cairo is a great cemetery containing the tomb of the Imán Esh-Sháfo'ee, and also an aqueduct, built by the sultan El-Ghooree, which conducts water from the Nile to the Citadel; and further south, the Roman fortress of Egyptian Babylon, now called Kasr-esh-Sheima, at present chiefly occupied by a Coptic convent, as well as the small town of Masr El-Ateekah, which is all that remains of the famous metropolis El-Fustát. It contains no remarkable edifices: in its immediate neighbourhood, however, is the oldest mosque in Egypt, that of 'Amr, the Muslim conqueror, but it has been so frequently repaired and almost rebuilt that it is impossible to form any idea of its original appearance. Opposite to Masr El-Ateekah, from which it is separated by a very narrow branch of the Nile, is the island of Er-Ródah, containing the famous Mikyás, or Nilometer.

The chief place on the western bank near Cairo is the small town of El-Geezeh, opposite Masr El-Ateekah. El-Geezeh is best known as having given its name to the most famous group of Pyramids, the chief monuments of Memphis, which stand on the slightly elevated border of the low Libyan range, not more than a quarter of a mile beyond the limit of the cultivated land.

The city of Memphis, MEN-NOFER, "the good station," stood on the western bank of the Nile about ten miles above Cairo. It was founded by Menes, the first king of Egypt. The kings and people who dwelt there chose the nearest part of the desert as their burial-place, and built tombs on its rocky edge, or excavated them in its sides. The kings raised pyramids around which their subjects were buried in comparatively small sepulchres. The pyramids were grouped together, and often there is a long distance from one group to another. Although many pyramids have been nearly or wholly destroyed, yet, as the largest undoubt-

edly remain, the general features of the necropolis cannot be much changed. From the Citadel of Cairo we obtain a good view of the several groups. First, opposite to us, but a little to the south, are the three great Pyramids of El-Geezeh, two of which exceed all the others in magnitude; at some distance farther south we see those of Abou-Scer, likewise three in number, of smaller dimensions, and, not so far beyond them, the great Pyramid of Sakkarah, called from its form that of Steps, with smaller pyramids in its neighbourhood. Farthest of all, after a wider interval, are the two large Pyramids of Dahshoor, which approach in size the two great structures of El-Geezeh. There are more to the south as far as the Feiyoom, the last being that of El-Lahoon, but none above the Pyramids of Dahshoor can be included within the Memphite necropolis. That great tract extended, if we measure from the ruined Pyramid of Abou-Ruweysh, somewhat to the north of those of El-Geezeh, to the southernmost Pyramid of Dahshoor, throughout a space of nearly twenty miles, in almost every part of which some sepulchres have been discovered, while it cannot be doubted that many more await a fortunate explorer.

The road to the pyramids of El-Geezeh from the town is through cultivated fields diversified by villages in palm-groves. As we approach them, these structures do not give us that idea of size that we had expected from our first distant view; and until we stand at their feet we do not appreciate their vastness. But as we endeavour to scan the height of the Great Pyramid, when about to begin its ascent, we fully realize a result that human labour has not achieved elsewhere. The very dimensions (a height of about half a thousand feet, four sides each measuring the seventh of a mile) are in themselves gigantic, but when we know that this huge space is almost solid, containing a few chambers so small as not to be worthy of consideration in calculating its contents, we discover that no monuments of man's raising elsewhere afford any scale by which to estimate its greatness. The Pyramids, except one or more small ones, were tombs of kings. Each had its name and a priest attached to it, for whose functions there was a chapel at some distance in front of the entrance.

The Great Pyramid, "the Splendid," was the mausoleum of Khufu, or Cheops, of Dynasty IV. The present perpendicular height of the structure is, according to General Vyse, 450 feet 9 inches, and the side of its present base 716 feet. It is about 30 feet lower than it was originally, in consequence of the casing stones and much of the outer masonry having been torn off; and its base is likewise smaller. General Vyse gives the former height at 480 feet 9 inches, and the side of the former base at 764 feet. Like all the other pyramids, it faces the cardinal points. At the completion of the pyramid the faces were smooth and polished, but now they present a series of great steps formed by the courses of stone, and are in some places (particularly in the middle of each face, and at the angles, and about the entrance) much broken. The ascent is easy though fatiguing, and the traveller is amply rewarded by the view which he obtains from the platform, about 32 feet square, at the summit. The prospect of the fertile plain and valley on the one side, and of the undulating barren surface of the Great Desert on the other, as well as of the pyramids and tombs beneath, is alike remarkable from its character and the associations which it calls up. The examination of the interior is no less interesting. All other tombs but the Memphite pyramids, and those which were simply pits, were not closed, the upper chamber being intended for the performance of funeral rites when the family of the deceased visited his sepulchre. These pyramids, however, were most carefully closed. The chambers which contained the bodies of the king, and of those (doubtless of his family) who were sometimes buried

in the same structure, are without sculptures, and scarcely ornamented in any way, being usually wholly plain. The passages leading to them are only large enough to admit a sarcophagus, and after the king's burial were closed by the lowering of heavy stone portcullises, and the blocking up of the entrance. The desired object was security, and we must not, therefore, expect beauty or grandeur in chambers constructed for this purpose, although we cannot fail to admire their massive and gloomy aspect.

The entrance of the Great Pyramid is not far from the middle of the northern face, 49 feet in perpendicular height from the base. The fallen stones and rubbish have, however, raised a mound which reaches nearly to the entrance, the masonry about which having been torn down, we gain some idea of the construction of the pyramid. In this manner the passage has lost somewhat of its length. The passage itself is 3 feet 11 inches high, and 3 feet $5\frac{1}{2}$ inches wide, and is lined with fine limestone. It descends at an angle of $26^{\circ} 41'$.¹ At a distance of 63 feet 2 inches from the beginning of the roof of the present entrance, a second passage commences from this, taking an ascending direction. The entrance of this new passage is obstructed by great blocks of granite which entirely fill it, and have been passed by means of an excavation around them. We thus enter the ascending passage, which is of the same breadth and height as the former, and inclines at an angle of $26^{\circ} 18'$. The stones which line its roof and sides are very rough, and it has evidently been left unfinished. After ascending this passage for a distance of 109 feet 7 inches, we reach the Grand Passage, which, from its greater dimensions, presents a comparatively imposing appearance. It ascends at the same angle as the last, while a horizontal passage runs beneath it to a chamber to be subsequently mentioned. Just within the Grand Passage is the mouth of the Well, an irregular pit, partly excavated in the rock, leading to the lower portion of the first passage. Its object was probably to afford an exit to the workmen who had been engaged in closing the ascending passage. The Grand Passage is 6 feet 10 inches in width at its base, 28 feet high, and 156 feet long. The blocks which compose its sides gradually approach, every course above the second projecting a little, and on each side is a stone bench. At the end of this passage a horizontal one begins, of much smaller but unequal dimensions, and 22 feet 1 inch in length, leading to the Grand Chamber, commonly called the King's Chamber, which it enters at the eastern end of its north side. This, which is the principal sepulchral chamber (unless, indeed, there be an undiscovered one of greater importance), is lined with red granite, and measures in length 34 feet 3 inches, in width 17 feet 1 inch, and in height 19 feet 1 inch. It is altogether plain, and contains only a sarcophagus of red granite, which is equally unadorned. Above this chamber are five small ones, which may be called entresols, evidently designed to lighten the pressure of the superincumbent masonry, particularly as the uppermost of them has a pointed roof. Four of these were discovered by the late General Howard Vyse, who found in them quarry-marks, bearing, in two varieties, the name of Khufu, the royal builder of the pyramid. These chambers are reached with difficulty, and chiefly by forced passages. The horizontal passage beneath the Grand Passage must now be described. This is but 3 feet 10 inches high, and

¹ See Sir John Herschel's "Observations on the Entrance Passages in the Pyramids of Gizeh," in Vyse's *Pyramids of Gizeh*, vol. ii. 107-109. The different angles of the entrance passages of other pyramids, and the circumstance that they were always closed at the completion of the buildings, show that the fact of this one's having pointed, at a supposed date of its erection, to α Draconis, which was then the pole-star, is not to be regarded as more than accidental. Nevertheless, as above mentioned, the pyramids face the cardinal points.

3 feet $5\frac{1}{2}$ inches wide, for the first 92 feet of its length, and then we descend a step and find the passage to be 5 feet 8 inches high for 17 feet 11 inches farther, until it enters the "Queen's Chamber," as it is usually called, at the eastern corner of its north side. This chamber is 18 feet 9 inches long, and 17 feet broad, and its extreme height is 20 feet 3 inches. It has a pointed roof, of great blocks of stone, inclined upwards and meeting in the middle. Within it is the entrance of a forced passage. The remainder of the first passage, beyond where the first ascending passage leads to the most interesting parts of the structure, is still to be noticed. It continues below the forced entrance to the ascending passage for a distance of 239 feet 10 inches, being cut through the rock on which the pyramid is built. For this space its inclination and proportions do not change, but it then becomes horizontal for 27 feet, terminating at the entrance of an excavated chamber 46 feet in length, and 27 feet 1 inch in breadth, but of irregular and inconsiderable height. There is no doubt that this chamber was left unfinished at the closing of the pyramid. Beyond it the passage continues, opposito to where it entered the chamber, and extends horizontally 52 feet 9 inches into the rock in the same direction.

The Second Pyramid, which bore the name of "the Great," and was the tomb of Khafra, or Chephren (Dynasty IV.), stands at a short distance to the south-west of the Great Pyramid, which does not very much exceed it in magnitude, though far superior in its construction. It has a base of 690 feet 9 inches square, and is 447 feet 6 inches in height, being more steep than its larger neighbour. A great part of its casing having been preserved, extending about a fourth of the distance from the summit, the ascent is very difficult, especially as when one has climbed on to the cased portion he can see nothing of the lower part of the building, and thus feels as if upon a pyramid in the air. There are two entrances, both in the north side, from which, and other peculiarities, it is possible that the building was originally much smaller than now, and that, after its first completion, it was enlarged, and a new entrance and sepulchral chamber added.

The Third Pyramid, "the Superior," the tomb of Menkanra, or Mycerinus, is almost in a line with the other two, and of much smaller dimensions, being only 203 feet in height, and 354 feet 6 inches square at the base. It is constructed beautifully, and in a costly manner, and in these respects is unexcelled, if equalled, by any other pyramid. The exterior was anciently cased altogether, or in part, with granite, but this has been generally torn off. General Vyse opened it, and found that it had been previously ransacked. In it he discovered a very beautiful sarcophagus (which was unfortunately lost at sea on its way to England), as well as part of a mummy-case, bearing the name of King Menkaura, and a mummy, not certainly the king's, both of which are now in the British Museum. This confirms the statement of Herodotus that it was the tomb of Mycerinus. Manetho says that it was built by Queen Nitocris (Dynasty VI.) This apparent inconsistency is explained, as Bunsen remarks (*Egypt's Place*, ii. 165, *seq.*, 210, *seq.*), by the construction of the pyramid, which has two principal chambers, and was evidently enlarged after its first completion, so that we may reasonably suppose that it is the sepulchre of both Mencheres and Queen Nitocris.

Near the three large pyramids are six smaller ones; three of these are near the east side of the Great Pyramid, and three on the south side of the Third Pyramid. They were probably the tombs of near relations of the kings who founded the great pyramids. The space around the pyramids is occupied by very numerous tombs, some built of stone, others excavated in the sides of the rock on which

the pyramids stand, while others are simply pits with sepulchral chambers leading from them. The most interesting of these occupy a square bounded on the east by the Great Pyramid and on the south by the Second, and are mostly the sepulchres of the subjects of Khufu and other kings of Dynasties IV. and V. These tombs, which are of inconsiderable dimensions in comparison with many at Thebes and elsewhere, are all built of stone, and have inclined walls, so as to resemble truncated pyramids. They usually contain a chapel, or more rarely chapels, the walls of which are decorated with most remarkable painted sculptures, portraying the everyday life of the Egyptians at that remote age, with short inscriptions of an explanatory character. The absence of representations of the gods and subjects clearly connected with religion is noteworthy. Other similar tombs stand to the east and south of the Great Pyramid; and in the former direction are the principal sepulchral grottoes hewn in the side of the elevated rocky tract on which the pyramids stand. Some of these excavations bear similar representations to those of the other tombs already mentioned. To the east of the Second Pyramid is the Great Sphinx, called in Egyptian "hu," emblem of Hor-em-akhu, "Horns in the horizon," one of the most characteristic monuments of this wonderful necropolis, of an earlier date than the Great Pyramid. It is a recumbent androsphinx, or man-headed lion, 188 feet $9\frac{1}{2}$ inches in length, hewn out of a natural eminence in the solid rock, some defects of which are supplied by a partial stone-casing, the legs being likewise added. Steps lead down to its front, where are a sanctuary and tablets, but these are covered by the sand, which, after the hollow has been cleared, speedily fills it again. Not far to the westward of the Sphinx is the remarkable excavation known as Campbell's Tomb, discovered by General Vyse, chiefly consisting of a large pit surrounded by a trench. The causeways leading to the Great Pyramid and to the Third, the former of which greatly excited the admiration of Herodotus, are well worthy of a careful examination. The only pyramid which stands to the north of this group is that of Abou-Ruweysh, which is in so ruined a condition as scarcely to deserve a visit. It lies about five miles to the north of the Great Pyramid.

Southward of the Pyramids of El-Gezeh, the first objects of interest are those forming the similar group of Abou-Seor, of much smaller dimensions, the largest being about the size of the Third Pyramid. They are on the elevated edge of the Libyan chain, about seven miles from the Third Pyramid, and are four in number, three being large, and the fourth very small. The Northern Pyramid of Abou-Seor appears to have been the tomb of Sahura of Dynasty V., and the Middle Pyramid is the tomb of Ranuser of the same line.

About two miles farther in the same direction are the Pyramids of Sakkarah, the greatest and most remarkable of which is called the Pyramid of Steps. The tract around them appears from the number of the tombs to have been the principal burialplace of Memphis, to which it is near. The Pyramid of Steps has a height of 196 feet 6 inches, and its base formerly measured on the north and south sides 351 feet 2 inches, and on the east and west 393 feet 11 inches. Within it are numerous passages and a gallery, which must, for the most part, have been made subsequently to the completion of the structure. In the centre is a very lofty and narrow chamber, and near it a small one, which was lined with blue tiles. In the latter was an inscription containing the title of the bulls Apis. Under the old monarchy those sacred animals were here entombed. It is thought that this pyramid was constructed by Unenphes of Dynasty I. If Manetho be correct in assigning the introduction of the worship of Apis to a later king, this

pyramid, if of Ucnephres, was originally a royal sepulchre. In the tract between the Pyramids of Sakkarah and Abou-Seer are the remains of the Sarapeum, and the burialplace of the bulls Apis, both discovered by M. Mariette. They are inclosed by a great wall, having been connected, for the Sarapeum was the temple of the defunct Apis. The tombs are in subterranean galleries or in separate excavations which contain many sarcophagi, in which the bulls were entombed. Not the least important result of this discovery is the certainty that Sarapis was a form of Osiris, and that his name was Hesiri-hâpi, or Osiris-Apis (Brugsch, *Reiseberichte aus Aegypten*, 27, seqq.), as Sir Gardner Wilkinson had long previously suggested (*Materia Hieroglyphica*, 21, and Vocab. MS. addition). The other pyramids are of comparatively little interest. There are also some curious private tombs, among which may be particularized a large grotto excavated in the face of the rock overlooking the valley, which is remarkable for being vaulted on the principle of the true arch, but without a key-stone. It is of the time of Psammetichus I. of Dynasty XXVI., being, as Sir Gardner Wilkinson remarks, one of the two earliest known examples of the arch in stone, though, as he adds, there are brick arches at Thebes of the time of Amenophis I. of Dynasty XVIII. (*Modern Egypt and Thebes*, i. 368-9).

The site of Memphis is marked by mounds in the cultivated tract to the east of the Pyramids of Sakkarah, and near the village of Meet-Rahconeh. Of the great temple of Ptah, its tutelary divinity, there are no remains above ground, except a few blocks of stone and some broken statues, one of which is a fine colossus of Ramses II., which most probably stood in ancient times before one of the principal entrances of the temple. It is of white chert, and beautifully executed, representing the king in a standing posture. It has fallen to the ground, and has lost part of its legs; nevertheless it has suffered considerable damage elsewhere, so as to be still one of the finest specimens of Egyptian art. The original height was more than 40 feet. This colossus is the property of the British nation, but no steps have been taken to remove it to this country. As Sir Gardner Wilkinson remarks, "when the Turks have burnt it for lime, it will be regretted" (*Modern Egypt and Thebes*, i. 373). The site of Memphis being in the cultivated tract, and near the modern capitals of Egypt, its monuments have alike suffered from the destructive power of nature, and from the barbarism of those who have used them as quarries or defaced them from motives of fanaticism. The Pyramids have not escaped man's violence, but their vastness has generally defied his attacks.

At a distance of about five miles to the south of the Pyramid of Steps is the northernmost of the Pyramids of Dahshoor, an interesting group, of the history of which nothing certain is known. To their north is a vast truncated pyramid, the sepulchre of Unas, last king of Dynasty V., anciently called "the Most Beautiful Place," now Mastabat Farnoon, or "Pharaoh's Seat." Two of the Pyramids of Dahshoor are of stone, and three of crude brick. The former exceed in size all the other pyramids except the First and Second of El-Geezeh, and have remarkable chambers within them. The Northern Stone Pyramid has a base of 700 feet, and a height of 326 feet 6 inches, and has lost somewhat of its size, having originally measured 719 feet 5 inches, and 342 feet 7 inches. Some of the casing remains. It has an entrance in the northern face, leading to three chambers of similar construction to the Grand Passage in the Great Pyramid. The Southern Stone Pyramid is distinguished by the peculiarity of its form and by having two entrances, one in the eastern face and the other in the northern. The lower portion has an

angle of 54° 14' 46", but the inclination then changes to 42° 59' 26". It has been supposed that it was suddenly completed, having been originally planned to be much loftier, but the method in which the pyramids were built renders this unlikely; and it seems rather to have been given this form to gratify a whim of the founder, especially as the entrances in different faces afford another peculiarity. Its base is 615 feet 8 inches, and its height 319 feet 6 inches. At its southern side is a small brick pyramid. The Northern and Southern Brick Pyramids of Dahshoor are to the east of those already described. They are now in a very ruined state, being merely mounds of crude brick, one of them is probably the Pyramid of Asychis mentioned by Herodotus.

Among the earlier explorers of the necropolis of Memphis was Belzoni, by whom the Second Pyramid was opened. General Howard Vyse first undertook a complete examination of the series of pyramids, and having secured the assistance of Mr Perring, carried out this project with well-merited success. Professor Lepsius, the head of the Prussian expedition, opened many tombs in the Memphite necropolis, and has published in his magnificent work (*Denkmäler aus Aegypten und Aethiopien*) the most interesting sculptures which they contain. M. Mariette, aided by the French Government, discovered the Sarapeum and the tombs of the bulls Apis, and has since continued his researches under the authority of the Khedive.

The voyage up the Nile from Cairo may now be described. Not far south of Masr El-Ateekah, the mountain and desert approach very near the river on that side, and soon after the wide opening of a valley is seen. Beyond it is a bold promontory of the eastern range, which first gradually recedes and then becomes parallel with the river for some distance, leaving but a narrow strip of cultivated land. Behind the village of Turâ, the ancient Troja, are the quarries named after it, and a little farther to the south are those of El-Masarah. These quarries are great excavated chambers and passages, which are entered by large square apertures in the steep face of the mountain. Hence were taken the finer blocks of limestone employed in the construction of the Pyramids of El-Geezeh. Tablets in both quarries record the quarrying executed under different sovereigns. South of the quarries the character of the eastern bank continues unchanged, and presents no remarkable object until we reach the promontory of the Shèykh Abou-Noor, which will be subsequently mentioned. The western bank, on the contrary, is broad and fertile, abounding in villages, and above its palm-groves rise in the distance the massive forms of the long series of pyramids. Considerably beyond those of Dahshoor, which may be considered as the most southern in the Memphite necropolis, are the two Pyramids of El-Metânecyeh, which are too small to be seen from the river, and yet farther the solitary Pyramid of Meydoom, commonly called the False Pyramid. Dr Brugsch thinks it very probable that it was the tomb of Senofern, last king of Dynasty III. It is a structure of great size, having a base of about 400 feet, and a height of about 310 feet. In consequence of blocks having been pulled off its sides for building purposes, it has the appearance of being built in two degrees, the lower of which is much greater than the upper, while the fallen stones around its base make it seem as if raised upon an eminence to increase its apparent size, and hence its name. The entrance has not been discovered. Its position, rising alone above the rich valley and desert beyond, without any object by which to measure its size, render this pyramid, especially when seen from some distance across a broad part of the river to the north, a very striking object. There is nothing else worthy of a visit on the western bank until

we reach the town of Bence-Suweyf, about seventy miles by the course of the river from Cairo.

Bence-Suweyf is a busy town, being the port of the Feiyoom. A road leads hence to that province, in a north-westerly direction. After crossing the great canal called the Bahr-Yoesuf, we pass through the opening in the Libyan range which leads to the Feiyoom, leaving on our right the ruined brick Pyramid of El-Láhoon, so called from an adjacent village.

The Feiyoom, including its lake, is a pear-shaped tract (its narrowest part being to the west), extending into the desert, and measuring in its greatest length about thirty miles, and in its greatest breadth about twenty. The part now cultivated is more than two-thirds of this extent from the east. At the north-western extremity is the great lake of El-Karn, which is long and narrow, and fills the northern portion of the valley. A branch of the Bahr-Yoesuf flows through the opening leading to the Feiyoom. This canal soon spreads into many streams, two of which, after joining into a single course, carry off the superabundant waters of the inundation into the lake of El-Karn, while they contribute with the others to irrigate the cultivable tracts.

The site of the famous Labyrinth first claims our notice after entering the Feiyoom. Its position may be known by a ruined crude brick pyramid, that of Hawárah, which is spoken of by both Herodotus and Strabo, and may be called the Pyramid of the Labyrinth. The remains of the Labyrinth itself, which had been previously known, were first carefully examined by the Prussian expedition headed by Professor Lepsius, in 1843. The structure was so ruined, however, that the results were not as decisive as might have been hoped. Yet the plan was to some extent made out, and the building shown to have contained a great number of very small chambers, as ancient writers had said; and the discovery of royal names of Dynasty XII., particularly of Amenemhat III., to whom Manetho ascribes the founding of the Labyrinth, leaves little doubt that this king was the Mæris who built the Labyrinth, according to the classic writers. The use of this building has not been distinctly ascertained. Manetho indeed makes it to have been the founder's tomb, but it is most probable that he was buried in the pyramid, which, however, the Egyptian historian may have regarded as part of the Labyrinth, as it is evidently connected with that structure.

Not far beyond the site of the Labyrinth is the capital of the province, usually called "El-Medeeneh," or "the City," and "Medeenet-el-Feiyoom," "the City" or "Capital of the Feiyoom," close to the mounds of the ancient Arsinoë, or Crocodilopolis. It is a small but flourishing town. The only monuments of antiquity in its neighbourhood are the remains at Boyáhmoo somewhat to the north, and the great broken tablet at Begeeg, at a smaller distance to the south. The former are two structures supposed by some to be pyramids, and the latter, which is a record of the time of Usurtesen I., is usually called an obelisk, but it must rather be regarded as a very tall and narrow stele or tablet, upwards of 40 feet in height.

In this part of the Feiyoom, to the north of El-Medeeneh, may be traced the remains of that remarkable hydraulic work the Lake Mæris. M. Linant, a French engineer, was the first to determine the position and character of this famous work of antiquity; and the results of his investigations are in accordance with the opinions of some who had previously noticed the subject in published works (*Mémoire sur le Lac Mæris*, Soc Eg., 1843). The object of the Lake Mæris was to regulate the irrigation of the Feiyoom, anciently the Crocodilopolite Nome, and

afterwards the Arainoite; and it was valuable on account of its fisheries. It seems rather to have deserved the name of a very large reservoir than that of a lake. Notwithstanding the drying up of the Lake Mæris, the Feiyoom is still an important and fertile province. It produces very large quantities of grapes; and the fields of roses, cultivated for the sake of rose-water, present a remarkable appearance.

The great Lake of El-Karn is perhaps the most interesting object in this part of Egypt. Its name, Birket-el-Karn, signifies "The Lake of the Horn," or "Projection," by which an island is intended, and not its general form, as has been supposed. It is, according to Sir Gardner Wilkinson, about 35 miles long and about 7 broad at its widest part and is not deep, as far as has been ascertained. The water is brackish and unwholesome, though derived from the Nile, which has at all seasons a much higher level. It is bounded on the south by tracts in a state of cultivation, or deserted for want of labourers, though anciently cultivated, and on the north by the Libyan desert, above which rises a bold range of mountains; and it has a strange and picturesque wildness. Its northern shore was anciently cultivated, at least in part, but is now entirely waste. Near the lake are several sites of ancient towns, and the temple called Kasr-Károon distinguishes the most important of these. That temple, however, being devoid of sculpture, and doubtless of the Roman period, could not attract attention except in a region barren of monuments. After this cursory view of the Feiyoom we may return to the Nile and continue our southward course.

Not far south of Bence-Suweyf the eastern chain is washed by the river at the picturesque promontory of the Sheykh Aboo-Noor, whose tomb stands on its summit. From this point as far as the town of Mansaloot the mountains on the east are close to the Nile, leaving a narrow space of cultivable land, or none at all, while the western bank is far broader than before. For forty miles nothing remarkable attracts the eye except the lofty mounds of ancient towns, until one sees the well-proportioned minaret of a mosque in the large village of Semeloot, said to have been erected by the architect of the mosque of Sultan Hassan at Cairo. Not far beyond, the river washes the picturesque cliffs of Gebel-et-Teyr, or the Mountain of Birds, part of the eastern range. Upon its summit stands a Coptic convent, called the Convent of the Virgin, Deyr-el-'Adra. One of the monks of this convent usually climbs down the steep face of the mountain by a dizzy path, and swims to the traveller's boat to solicit alms as a fellow Christian. In this part of Egypt we first begin to notice the entrances of grottoes in the face of the eastern mountains, but none of these for some distance are known to be of any interest. Not far beyond Gebel-et-Teyr is the town of El-Minyeh, on the western bank, a place wearing a cheerful aspect. Opposite El-Minyeh are quarries and sepulchral grottoes, the most remarkable of the latter being at a site called El-Kóm-el-Ahmar, or "the Red Mound." These are of the age of Dynasties IV. and VI., but they have sustained so much damage in modern times that they do not repay a visit, except from one who is a student of hieroglyphics. A governor of El-Minyeh, an ignorant Turk, used these ancient tombs as quarries; and had it not been for the interference of Mr Harris of Alexandria, the more important grottoes of Bence-Hasan would have shared the same fate at his hands.

The first noteworthy objects above El-Minyeh are the sepulchral grottoes of Bence-Hasan, which are inferior to none in Egypt for beauty and interest. They are excavated in the face of the eastern mountains, which are here very low and sloping, and separated from the river by a small extent of debris and desert, and a very narrow strip of

cultivable land. The grottoes are almost in a line near the summit of the mountain, and at no great height above the river. The two northernmost are remarkable for having porticoes, each supported by two polygonal columns of an order which is believed to be the prototype of the Doric. Most of the grottoes are adorned with sculptures and paintings, which portray with eminent truthfulness and character the manners of the Egyptians of the remote period at which they were executed, for they are tombs of nomarchs and other governors of Dynasty XII. They generally consist of a chapel of large dimensions, having sometimes a portico before it, and a niche with seated figures of the chief persons buried in the tomb at the extremity, and have pits leading to sepulchral chambers. The principal apartment is sometimes supported by pillars cut out of the rock, and vaulted. Its walls bear representations of the diversions of the occupant during his lifetime, and of his varied occupations, in scenes depicting hunting, fishing, games, feasts, the processes of agriculture, and the like. The figures of beasts and birds, more especially the latter, are characterized by a remarkable fidelity and beauty, and there can be no doubt that Egyptian art had attained a greater excellence at this time than it possessed under Dynasty IV. A little to the south of these grottoes, in a ravine, is the Specos Artemidos, a small rock-temple of Sekhet or Pakht, the Egyptian Diana, and some sepulchres of little interest.

A few miles to the south of the Specos Artemidos are two sites, one on either side of the river, which were marked, in the present century, by most important monuments, which have since been destroyed by the Turks. That on the western side, near the large village of El-Ashmooneya, the ancient Hermopolis Magna, was part of a magnificent portico, bearing the names of Philip Aridæus, Alexander Ægus, and Ptolemy I., all that stood of the temple of Thoth; and on the opposite side of the river were considerable remains of the edifices of the town of Antaeopolis founded by Hadrian. While we regret the destruction of such interesting records, we must not charge either the Turks or the native Egyptians with all the mischief of this kind which is perpetrated, and our sorrow is increased by the reflection that to European travellers, principally Englishmen and Americans, must be assigned no small share in the destruction or mutilation of the monuments, which in the case of educated men is nothing less than a crime.

A short distance south of Antinoöpolis is the town of Mel-lawee, on the western bank, and a little farther, on the other side of the river, the promontory called Gebel-esh-Sheykh Sa'eed, which is honeycombed with grottoes, some of which are shown by their sculptures to be very ancient, but are so ill preserved as to require but a short examination. A little beyond, however, in the district of Tell-El-Amârineh, or the Mound of El-Amârineh, a small fertile tract where the eastern mountains recede, noted, like Benoo-Hasan, for the turbulent and thievish propensities of its inhabitants, are most curious remains of a very ancient town. It was the capital of Khu-n-aten, the sun-worshipper of Dynasty XVIII., and was no doubt destroyed by Horns, and not subsequently rebuilt. In the mountain behind it are very interesting sepulchral grottoes, in which were buried the courtiers of this king, and from them we obtain much information respecting his religion, a very pure form of sun-worship. The representations are chiefly of the king, his queen, and their children, distributing presents to the soldiers and others, of acts of worship to the sun, and of the temple of the sun as well as gardens and villas.

On the western bank of the Nile, a little to the south of Tell-el-Amârineh, is the small town of Deroot-esh-Shereef, supposed to be on the site of the Thebæica Phylæe, which guarded the northern boundary of the Thebæis. About 20

miles to the south is the town of Manfaleet, on the same side of the river, which has a decayed appearance from the manner in which the stream has encroached upon and washed away part of it. Opposite to Manfaleet in the eastern range are extensive crocodile-mummy catacombs. There is nothing of note during the next 25 miles of the river's course, which is very winding, until we reach the village of El-Hamra, the port of Asyoot. This town, the capital of Upper Egypt, or the Sa'eed, that is, of the whole country above Cairo, lies inland, about two miles from El-Hamra, in a richly cultivated plain. Asyoot, with its beautiful mosques, two of which, one of the Memlook style, and the other of the Turkish, are not unworthy of comparison with those of the metropolis, and its Constantinopolitan palace, surrounded on three sides by verdant fields, and having behind it a fine rounded spur of the western chain, which here, for the first time, is near the river, presents a picturesque aspect as the traveller approaches it. On entering Asyoot he is not disappointed, for the excellence of the goods and provisions sold in the well-built chief market, and the solid look of the houses, indicate activity and prosperity. And it is not a little remarkable that this was an important town some 4000 years ago, and has thus outlived Thebes and Memphis, Tanis and Pelusium. The ancient Egyptian name was Ssut, or probably Ssint, but the Greeks called it Lyceopolis, on account of the worship of the wolf- or jackal-headed divinity of the place, a form of Anubis. In the mountain behind Asyoot are some ancient grottoes, one of which is of great size, but their sculptures have unfortunately suffered much. The view of the valley and the town beneath is an ample reward for the ascent.

Thirty miles farther by the river, on the eastern bank, is the village of Kâw-el-Kobeereh, where was anciently Antaeopolis. The interesting remains of the temple of Antæus, which stood here early in the present century, have entirely disappeared through the encroachment of the river, and also, it is believed, from having been used as a quarry by the Turks. A few miles beyond, the lofty part of the eastern range called the Gebel-esh-Sheykh-El-Hareedee from a famous Muslim saint, leans in the river on one side for a short distance. It soon, however, retires again, and the valley on that side becomes broader than usual. Here, a short way from the river, stands the small town of Akhmeem, the ancient Chemmis, or Panopolis. No remains of importance mark this site. About 22 miles farther by the course of the river, on the western bank, is the important town of Girgâ, which was, until a comparatively recent period, the capital of the Sa'eed. The rise of Asyoot, however, and the agency of the river which is gradually washing it away, have contributed to its decline, and it wears a dilapidated aspect.

The city of Abydos was a few miles from Girgâ, in a south-westerly direction on the border of the desert, here separated from the Nile by a broad cultivated tract. Close to it was Thinis or This, the town of Menes. Two interesting edifices render Abydos worthy of a visit. They are both dedicated to Osiris, the chief divinity of the place. The southernmost of these is a temple of Osiris, in which we find the names of Raumes II. and his father Setco I. The other structure is smaller, and in a worse state of preservation than the other temple, and among its sculptures are the same names, those of Setco I. and Raumes II. Hence was taken the famous list of Pharaohs known as the Tablet of Abydos, which is now one of the most valuable objects in the British Museum, and M. Mariette has since discovered a corresponding tablet in the other temple, happily complete. In the desert near by are many sepulchres, remarkable on account of the interesting antiquities which have been discovered by clearing them out. The sanctity

of Abydos as a reputed burial-place of Osiris rendered this a favourite necropolis of the ancient Egyptians from very early times, particularly under Dynasty XII.

At a distance of more than 40 miles from Abydos, but in nearly the same latitude, is the village of Dendarah, on the left, here the southern, bank of the Nile. Before reaching it we pass the small town of Farshoot at the mouth of the great canal called the Bahr-Yoosuf, and the large village of Hoo, marking the site of Diospolis Parva. Opposite the latter place are some sepulchral grottoes in the eastern chain, called those of Kasr-es-Seiyád, which is believed to occupy the position of Chenoboscion. They contain names of kings of Dynasty VI., but the representations which occupy their walls are not of unusual interest. At Dendarah is the first well-preserved and unnumbered temple that is seen in a voyage up the Nile, that of Athor, the Egyptian Venus, who presided over the town of Tentyra, or Tentyris, the capital of the Tentyrite nome. It stands on the mounds of the town about a mile and a half from the Nile. From it we gain a good idea of Egyptian religious architecture under the Greek and Roman dominions.

The temple is surrounded by a great wall of crude brick, entered by a stone portal adorned with sculptures representing the emperors Domitian and Trajan, engaged in acts of worship before several divinities. The portico to which it leads is about 135 feet in width, and is one of the richest and most beautiful structures of the kind. It is supported by twenty-four columns, four deep, nearly 50 feet in height, and having a diameter of somewhat more than 7 feet at the thickest part. The capitals have a full face of Athor sculptured on each of their four sides, and above these a kind of shrine. The three columns on each side of the entrance are connected by an intercolumniation. The portico, like the rest of the temple, is of higher merit as regards its architecture than its sculpture, for the latter art had declined under the Greek and Roman rule to a much greater degree than the former. The sculptures are of the same kind as on the portal, representing offerings made by some of the earlier Cæsars; and on the ceiling are various mystical subjects, probably of an astronomical import, and the famous Zodiac from which an extravagant idea of the antiquity of the temple was deduced before hieroglyphics were interpreted. The greater part of the back wall of the portico was the front of the temple before this portion was added. This inner part consists of three considerable chambers, an isolated sanctuary, and numerous small apartments. The first of these is a hall, supported by a double row of columns, three on each side, of a rather heavy form, for they have, beneath the capital formed of the block with the faces of Athor and the shrine, another capital of a cup shape. This hall is entered by a doorway in the middle of the back wall of the portico, and passing through it we reach a second and third chamber of the same breadth but shorter, and then the sanctuary. This chamber is much narrower, and is isolated by a passage running round it. On each side of the chambers and passage are many small apartments, two passages to the exterior, and two staircases, and there are singular inclined passages in the walls, two of which are entered from the sides of the portico. The whole interior is covered with sculptures and inscriptions of a religious character, stating in a systematic manner the use of each chamber in the temple-worship. The royal names have not always been filled in, the rings remaining vacant; but when they have been sculptured, they are generally those of the last Cleopatra, and Ptolemy Cæsar, her son by Julius Cæsar. On the roof of the temple to which the staircases lead, there are a sort of chapel and some small chambers, one of which is very interesting, because its sculptures relate to the myth of

Osiris. The exterior of the temple is as completely covered with sculptures as the interior. Among the figures represented here are those of Cleopatra and Ptolemy Cæsar; but they cannot be supposed to convey any resemblance, since they belong not alone to a conventional art, but almost to its lowest period. There are two smaller temples near the great temple of Athor, one of Isis, and the other of the kind called a Typhonium. Both are of the Roman time. See admirable account of the temple in Mariette's *Monuments of Upper Egypt*, 125 seqq.

On the opposite side of the Nile, a little above Dendarah, is the town of Kiné, between which and Arabia some traffic is carried on by the route through the desert to El-Kuseyr on the Red Sea. The best of the porous water bottles which are used throughout Egypt are manufactured here, and the great water-jars, called "bellásee," which the women carry, are made at the large village of Bellás, a few miles higher on the western bank. Opposite to Bellás is the village called Kuft or Kift, marking the site of the important town of Coptos, which was the emporium on the Nile of the Arabian and Indian trade under the Ptolemies; and, somewhat to the south, is the inconsiderable town of Koos, the ancient Apollinopolis Parva, which succeeded to the trade of Coptos, under the Muslims, until Kiné supplanted it. On the western bank, a little higher, is the small town of Nakádeh, which the people call Nagádeh, where are Roman Catholic and Coptic convents. A short distance beyond Nakádeh are the northernmost of the remains of Thebes.

The monuments of Thebes do not present from afar the imposing appearance of the Pyramids of Memphis. Placed for the most part at a distance from the Nile, as well as from one another, and having on the western side the picturesque form of a much higher mountain than any near Memphis rising behind them, they do not strike those who see them from the river. Most of them are not indeed visible from the Nile except when it is at its height. The stately colonnade of the temple of El-Uksur, incorrectly called Luxor, on the very bank, is, however, not unworthy the magnificence of Thebes, and when one approaches the other monuments his utmost expectations are exceeded by the grandeur of El-Karnak, the beauty of the temple of Ramses II., and the mystery of the Tombs of the Kings. Nowhere else are the mythology, the history, the very life and manners of the Egyptians of old times so vividly brought before the eye as in the sculptured and inscribed monuments of the capital of the Empire.

Thebes, or Diospolis Magna, is called in the hieroglyphic inscriptions Ap-t, or, with the article prefixed, T-ap, whence Thebes, and Nu-Amen, the city of Amen, the No-Amon or No of the Bible. The date of its foundation is unknown, but there are remains of the time of Dynasty XI., the first of Diospolite kings. Under the sovereigns of Dynasty XII. it must have become a place of importance, but it probably declined during the troubles of the Shepherd period. With Dynasty XVIII. it attained its highest prosperity, and maintained it during Dynasties XIX. and XX. To this period its greatest monuments belong. Then its decline evidently commenced; but from the manner in which Homer mentions it (*Il* ix 381-4), Thebes must have been still a great city in his days. After this it suffered severely from the violence of the Assyrians and Persians, and lastly of Ptolemy Lathyrus, so that in Strabo's time the Thebans inhabited villages as now, and there was no longer a city (*Geogr.* xvii 1).

The monuments of Thebes, exclusive of its sepulchral grottoes, occupy a space on both sides of the river, of which the extreme length from north to south is about two miles, and the extreme breadth from east to west about four. The

city was on the eastern bank, where is the great temple, or rather collection of temples, called after El-Karnak, a modern village near by. The temple of El-Karnak is about half a mile from the river, in the cultivable land. More than a mile to the south-west is the temple of El-Uksur, on the bank of the Nile. On the western bank was the suburb bearing the name Menmonia. The desert near the northernmost of the temples on this side, the Setheum, almost reaches the river, but soon recedes, leaving a fertile plain generally more than a mile in breadth. Along the edge of the desert, besides the Setheum, are the Rameseum of El-Kurneh, and, less than a mile farther to the south-west, that of Medeenet-Haboo, and between them, but within the cultivated land, the remains of the Amenophium with its two gigantic seated colossi. Behind these edifices rises the mountain, which here attains a height of about 1200 feet. It gradually recedes in a south-westerly direction, and is separated from the cultivated tract by a strip of desert in which are numerous tombs, partly excavated in two isolated hills, and two small temples. A tortuous valley, which begins not far from the Setheum, leads to those valleys in which are excavated the Tombs of the Kings beneath the highest part of the mountain which towers above them in bold and picturesque forms.

The temple of El-Uksur is nearest of the edifices to the river, and but an appendage to the great group of El-Karnak. It takes its name from the small town of El-Uksur, or Abu-l-Haggag, which is built in and around part of it, thus injuring its effect, and rendering examination difficult. It differs from most Egyptian temples in not facing the river, but this is accounted for by its connection with the temple of El-Karnak, from the southern approaches to which a long avenue of sphinxes (now wholly ruined) leads to it, ending at its entrance. This is a massive propylon, or portal with wings, 200 feet in width, before which is a very fine obelisk of red granite. Its fellow, which stood on the western side, was removed by the French to Paris in 1831, and now adorns the Place de la Concorde. Both have beautifully cut hieroglyphic inscriptions. The height of that which remains is about 80 feet. It is adorned with three vertical lines of hieroglyphics on each side, bearing the titles of Ramses II. The other obelisk differs from this only in being slightly shorter. Close to the winged portal are three seated statues of red granite representing Ramses II.; a fourth has been destroyed. The wings of the portal are covered with sculptures of remarkable interest, representing occurrences in the war of Ramses II. with the Kheta or Hittites, in his fifth year. On the left wing is depicted the defeat by the Egyptians, led by their king, of the confederate peoples under the walls of the Hittite stronghold called Ketesh, or Kadesh, on the Orontes. The king is represented, according to the Egyptian custom, of a gigantic size, standing in his chariot, which he has urged into the midst of the hostile force, whose warriors fall by his well-directed arrows. The Egyptians, on the other hand, sustain no loss. On the right wing is represented the Egyptian camp. This has been sculptured over another subject, of which part may be now seen, owing to the falling out of the plaster with which it had been filled. All these representations are in sunk relief, and beautifully executed.

The entrance to the temple is contracted by a modern wall, through the small door of which we pass into a great court choked by the huts of the town, among which stands a mosque. The court is surrounded by a double row of columns, the capitals of which have the form of the bud of the papyrus. A ruined portal with wings forms the end of this court, and with it begins the older part of the edifice, which has a more southerly direction; and its southernmost part in like manner turns a little more in

that direction, that is, from the river, though not so remarkably. Some deviation was probably rendered necessary by the course of the Nile. The second court is much obstructed by rubbish; nothing is seen of it but a magnificent central avenue of fourteen columns, having capitals of the bell-shaped flower of the papyrus. The columns are about 60 feet in height, of fine form, and elegantly sculptured. They were raised by Amenophis III., whose name is the oldest which occurs on them and in the rest of the temple. Behind this is another court, which has a double row of columns on each side, and at its end a portico supported by columns four deep. This court is much ruined. Beyond it are several chambers of the time of Amenophis III., and in the midst of them an isolated sanctuary, the sculptures of which bear the name of Alexander *Ægus*, in whose reign it was built, in the place, no doubt, of one destroyed by the Persians under Cambyzes or Oehus, as Sir Gardner Wilkinson remarks (*Modern Egypt and Thebes*, ii. 245). Most of these apartments are in a dilapidated state.

Although there is an approach to the temple of El-Karnak from that of El-Uksur, the grand entrance was towards the river, and from that direction it should be entered. This extraordinary assemblage of buildings consists of a great temple and several smaller structures, surrounded by a massive crude brick wall. There are other remains similarly inclosed, which were connected with the great temple.

The grand entrance is through a propylon more than 360 feet wide, for this is its measure above the rubbish which is piled up around it. It was never sculptured, nor was its surface smoothed. It presents, therefore, a rude appearance, and is much ruined, a great part of the left or northern wing having been demolished. The court of which the propylon forms the front measures 329 feet in width and 275 in length, having on each side a gallery with a single row of columns, and a double colonnade, of which one column alone stands, formed an avenue from its entrance to that of the hypostyle hall beyond. On the right side a temple of older date interrupts the side gallery, extending 50 feet into the court. Its front is formed by a propylon, about 90 feet wide, on each wing of which Ramses III. is portrayed in the act of slaying prisoners before Amen-ra. The interior of this temple consists of a court, which has on each side a row of Osiridean pillars, and at the end another row of such pillars with columns behind them, a hall or portico supported by eight columns, next to the court, and, beyond, other apartments. Nearly all the sculptures are of the reign of Ramses III., but the names of later sovereigns occur. On the other side of the great court is a small structure which may be called a chapel, or three chapels. The most interesting sculptures in this part of the group of temples are outside the eastern portion of the south wall of the great court, for here is the famous list of countries and towns subdued by Sheshonk I., or Shishak, the head of Dynasty XXII. Among the names is that thought to be the kingdom of Judah, and those of several places in the dominions of Rehoboam and Jeroboam I. At the end of the court is a fine portal, the wings of which are much ruined. This is the entrance to the great hypostyle hall, the most magnificent work of its class in Egypt. Its length is 170 feet, and its width 329; it is supported by 134 columns, the loftiest of which are nearly 70 feet in height, and about 12 in diameter, and the rest more than 40 feet in height, and about 9 in diameter. The great columns, 12 in number, form an avenue through the midst of the court from the entrance, and the others are arranged in rows very near together on each side. There is a transverse avenue made by two rows of the smaller columns being placed farther apart than the

rest. This great hall is therefore crowded with columns, and the effect is surprisingly grand. The spectator, being generally unable to see beyond the columns which are immediately around him, perceives the vast dimensions which, if viewed from a distance, might lose their effect. The forest of columns seems interminable in whatever direction he looks, producing a result unsurpassed in any other Egyptian temple. The partial ruin of its stone roof, and of some of the columns, renders the hall the more picturesque, and makes us wonder at the force which must have been expended in attempting to demolish it. This grand hall was built by Setec I., Dynasty XIX., and sculptured partly in his reign and partly in that of his son and successor Ramses II., who has sometimes effaced his father's name to substitute his own. It commemorates, not in its grandeur alone, but also by its sculptures, the magnificence and power of these two great Pharaohs. The sculptures of the interior of the walls represent these kings making offerings to the gods, and the like subjects occupy the columns. Far more interesting are those which adorn the exterior of the walls, and record the achievements of the same kings, those of Setec I. being on the north wall, and those of Ramses II. on the south. The former are of much greater interest than the latter, as far as we can judge, and in this respect inferior to none in Egypt. The scenes on the north wall are arranged in three compartments, of which the upper one has been nearly destroyed. In these scenes the king is represented of a gigantic size, charging in his chariot, and putting to the rout his enemies, capturing their strongholds, and returning home in triumph. The chief nations are the *Kheta* or Hittites, the *Ruten* (*Luten*), at this time a great nation of Syria; the *Shasu*, or Arabs; the *Khalu*, Syria, or Syrians; and *Remenen*, Armenia. Among the captured places is *Ketesh*, in those days the most important stronghold between Egypt and Mesopotamia. There is also a long list of countries, cities, and tribes, conquered or ruled by the king, among which we find *Naharina*, that is *Aram-naharaim*, or Mesopotamia, *Kesh*, *Kush*, or Ethiopia, &c. The battle-scenes of Ramses II. on the south wall do not, as far as they are seen, equal these in interest. Here also is a list of the king's conquests and possessions, and on the west side of a wall which joins this one at right angles, forming the side of a court of the southern approach to the temple, is a representation of the capture of *Askelena* or *Ascalon*, and an inscription recording the treaty between Ramses II. and the *Kheta*, concluded in the twenty-first year of his reign. The back of the hypostyle hall is formed by a ruined propylon bearing the name of Amenophis III., and then at a distance of about 50 feet is another propylon, entirely ruined. In the space between these propyla, which was a court, stands a beautiful obelisk of red granite, upwards of 70 feet high, raised by Thothmes I. The fragments of its fellow, which was more to the north, strew the ground. Behind the second of these propyla is another granite obelisk, 108 feet high, and according to M. Mariette the loftiest known (*Monuments of Upper Egypt*, 170). This great obelisk of El-Karnak is a monument of Queen Hatshepu of Dynasty XVIII., and an inscription on its pedestal records the period which elapsed (nineteen months) from the time that it was begun to be cut in the quarry until its completion in the queen's sixteenth year. The fellow of the great obelisk, which stood to the south of it, has been broken, and its fragments occupy its place. Beyond the great obelisk is the chief sanctuary, a structure almost entirely of granite, divided into two apartments, which was built under Philip Aridæus, in the place, no doubt, of one destroyed by Cambyzes or Ochus. The space between the hypostyle hall and this sanctuary is extremely ruined, the huge stones being piled up in heaps as though an earthquake had overthrown the temple. But this

destruction was probably due to human violence. Behind the sanctuary are fragments of a very ancient part of the temple, bearing the name of Usartesen I., Dynasty XII. Considerably farther is a large oblate building of the time of Thothmes III., which affords a remarkable example of architectural caprice, its columns having inverted shafts and capitals, and its cornices being likewise inverted. Behind this and a stone wall of inclosure are ruined chambers, and far beyond, directly behind the centre of the great temple, in the crude brick wall of inclosure, is a handsome portal, never finished, bearing the name of Nectanebes II.

The southern approach to the temple of El-Karnak from that of El-Uksur is, as before mentioned, by a ruined avenue of sphinxes, which ends near the great structure, and two other avenues begin. The westernmost of the two, which is of colossal runs, conducts to a temple situate not far to the south-west of the first court of the great temple: we approach it through a stately portal bearing in its inscription the name of Ptolemy Euergetes I. The front of the temple, before which was another avenue of runs, is a propylon, which is almost uninjured. Behind it is a court having a double row of columns on each side and at the end, and again behind this is a hall supported by eight columns, and many small chambers. This temple was dedicated to Khnum, the third member of the Theban triad. It was begun under Dynasty XX., and continued by the high-priest kings. A small edifice having sculptures of the time of the Greek and Roman rule stands on the west of the court of this temple.

The avenue of sphinxes which branches off at the same place as the avenue of runs leading to the temple of Khnum takes an easterly direction and ends where another begins at right angles to it, which connects the southern courts leading to the great temple with a separate inclosure. The latter contains a lake which has the shape of a horseshoe, and the remains of the temple of Mut. At the northern extremity of the avenue, which is of criosphinxes, is a propylon forming the front of a large court ending in a second propylon, which, like the other, is much ruined. Beyond this, but not in exactly the same direction, after a vacant space, the approach continues through two smaller propyla, the second of which is nearly destroyed. Each fronts a court, and at the end of the second of these courts was the great side entrance to the temple. The first and second propyla were, like the criosphinxes, monuments of King Har-em-heb, or Horus, of Dynasty XVIII., and were partly built of materials of a temple or palace of the sun-worshipping kings whom he overthrew. The third propylon is more ancient, for it bears the name of Thothmes III. and Amenophis II., as well as of subsequent kings; the age of the fourth is not certain; the name of Ramses II. occurs here, but it may have been founded before his time. There is an inclosure in the angle formed eastward by the third and fourth propyla with the great temple, which contains a sacred lake.

Adjoining the great crude-brick wall of inclosure at its north-eastern portion is another containing the ruins of an important temple. The chief approach is through a stately portal of the Ptolemaic period, in the crude-brick wall. The temple to which it conducted was very beautiful and costly, as we can judge from its remains, which show with how much violence it was destroyed. It seems to have been founded under Dynasty XVIII. There are two small temples or chapels, one of the time of Achoris and the other of that of Nectanebes I. and II., in the same inclosure. Another crude-brick inclosure of small dimensions, near the south-east corner of that of the great temple, contains some unimportant remains of a small edifice.

This brief description will convey some idea of the magnitude of the temple of Amen-ra at Thebes, with its

appendages; but no one who has not seen that wonderful assemblage of ruins can picture to himself the massiveness of its castle-like propylon, the grandeur of its hall of columns, the beauty of its great obelisk, and the sublimity of its heaped-up ruins. Of the city of Thebes there are scarcely any remains. Doubtless its edifices were of perishable materials.

Beginning our examination of the monuments of the western bank, where was the great suburb of the Memnonia, from the northward, the first object of interest is the Setheun, a small temple of Setee I., which the natives call Kasr-Er-Rubeyk, at the ruined village of El-Kurneh. A portico, originally supported by ten columns, of which two have fallen, extends along the whole front of the building. Three entrances lead to the interior of the temple: the middle one of these is the door of a hall having twelve columns. From this apartment we pass into several small chambers, which are of little interest, like the ruined chambers which we enter from the northern door. The southern door is the entrance of a separate part of the edifice, which contains a small hall supported by two columns, and three chambers behind it, the middle one of which was a sanctuary or chapel, devoted, as its sculptures show, to the worship of Ramses I., the father of Setee I. The inscriptions of the temple tell us that it was dedicated to Amen-ra by its founder Setee I., and continued by his son Ramses II., and his grandson Meuptah. It was the funeral chapel of the tombs of Ramses I. and Setee I.

The great temple of Ramses II., which may be called the Rameseum of El-Kurneh, but is commonly though incorrectly known as the Memnonium, is situate at a distance of about a mile to the westward of the Setheun, and is like it on the edge of the desert, which here is much farther from the Nile. Notwithstanding that its condition is much more ruined than that of other edifices of Thebes, the beautiful architecture of what remains, and the historical interest of its spirited sculptures, render it altogether second alone in its attractions to the great pile of El-Karnak. A propylon, 225 feet in width, of which a great part has been thrown down, forms the front of the edifice. Through its portal we enter a spacious court 180 feet wide and 142 long. It had originally a double colonnade on either side, every column of which has been destroyed, while the side walls have been entirely demolished and the end wall partially. On the back of the propylon are sculptured a battle and other scenes of a campaign in the king's eighth year. In this court is one of the most wonderful objects at Thebes, a colossal statue of Ramses II., broken in pieces, exceeding in its weight and equalling in its dimensions any other known Egyptian statue. It was of a single block of red granite, and must have been transported hither from the quarries of Syene, notwithstanding that its weight was, according to Sir Gardner Wilkinson's computation, about 887 tons, 5½ cwt. (*Modern Egypt and Thebes*, ii. 144, 145). It was 60 feet in height, representing the king seated on his throne, and was placed on the left side of the entrance to the second court. Of that court, happily, there are more remains than of the first. Its width was about 170 feet and its length about 140, so that it was not much smaller than the other court. It had a double colonnade on each side and at the end, and but a single colonnade at the front. These were of columns having capitals of the form of the papyrus bud, except eight of the ten forming the front row, that is, all of that colonnade but the two extreme columns, and, in like manner, the corresponding ones of the opposite row, which were Osiridean pillars, formed of a square block, having in front a figure of Ramses as Osiris. Many of the columns and pillars have been demolished; but those which yet stand enable us to judge how magnificent this part of the temple must have

been. On what remains of the front wall of the court, that is, on its northern half, are very remarkable sculptures. Here is a great scene representing a battle between the Egyptians, led by Ramses II., and the Kheta or Hittites, near the strong city of Ketesh. The king of Egypt is portrayed routing the chariots of the enemy, who flee in disorder towards Ketesh, across a double moat, beyond which and beneath the city a strong force of regular infantry endeavours to protect their retreat. This was doubtless the decisive action of the campaign against the confederates, which must be regarded as the most important of the wars which distinguished the reign of Ramses II. Higher up on the same wall is a procession of priests bearing small statues of kings, the first of which is that of Menes, the earliest sovereign of Egypt, the second of a Munt-hotp, of Dynasty XI., and the subsequent ones of the kings of Dynasties XVIII. and XIX., as far as Ramses II., with whom the series ends.

Next to the second court is a hypostyle hall, which is the most admirable part of the temple. It measures 100 feet in length and 133 in breadth, and originally contained forty-eight columns in eight longitudinal rows, each consisting of six columns. A central avenue is formed by twelve lofty columns, about 36 feet high, which have capitals of the shape of the papyrus flower; while the columns on each side, about 24 feet high, have capitals of the shape of the bud of the same flower. The elegance of the form and the justness of the proportions of all these columns is not equalled in any other Egyptian temple, and render this hall one of the most beautiful structures of its kind. Happily, although much injured, it has suffered less from violence than the first and second courts. On its front wall, to the left as one enters, are curious sculptures, representing the rout of a hostile force, and the capture of a town, the walls of which the Egyptians ascend by means of scaling ladders: Ramses II. and six of his sons lead the army. On the end wall are religious subjects, and a series of the sons and daughters of Ramses II., whose legitimate offspring they seem to have been, twenty-six in number, twenty-three sons and three daughters. At the temple of Wadec-es-Suboo'a, in Nubia, a much larger number of children of this king were represented.

Beyond the hypostyle hall are two smaller chambers, the first of which is entered by a doorway in the middle of the end wall of the hall. It is supported by eight columns, and has on its walls representations of mythological subjects. It is chiefly remarkable, however, for its astronomical ceiling, one of the most precious records of ancient Egyptian science. Behind this is a ruined chamber, which seems to have been of the same dimensions. The other apartments which must have adjoined these are entirely demolished. This temple was the chapel of the king's tomb. The description which Diodorus Siculus gives from Hecataeus of Abdera of the Tomb of Osymandyns agrees best with the Rameseum of El-Kurneh; and the mention of the sacred library is in accordance with the character of the sculptures of the first chamber beyond the hypostyle hall, as well as with the statement in several papyri that they were written by the scribes in this temple, in which, or attached to which, was a kind of college (*Lepsius, Chronologie der Aegypter*, i. 39, 53).

To the south-west of the Rameseum of El-Kurneh, at a distance of less than half a mile, a mound just within the cultivable plain marks the site of a magnificent temple of Amenophis III., which may be called the Amenophium, and which, there is reason to believe, was destroyed by Cambyses. Of the obelisks and colossi which stood on either side of the approach of the Amenophium, all are thrown down except the two gigantic statues, one of which is known as the Vocal Memnoil. The latter indeed, was

broken, but afterwards restored. These colossi stand about a quarter of a mile to the south-east of the mound where are the scanty remains of the temple. They are of hard gritstone, monolithic, and about 47 feet in height, with pedestals about 12 feet high. They represent Amenophis III. seated on his throne. Smaller though colossal standing statues of the king's mother, Queen Mut-em-wa, and of his wife, Queen Tai, rest against the space between the sides of the throne and the legs of the great statues, one at either extremity; while there are remains of two other statues of Queen Tai, of smaller size, standing between the feet of each colossus. The colossi are a little less than 60 feet apart, a distance judiciously chosen, so that they should neither seem smaller than they actually are, by being placed too far from each other, nor should be so near as to appear but a double statue.

The Vocal Memnon is the more northern of the two statues. It was broken in the midst either by the barbarism of Cambyses, or by an earthquake, more probably the former (comp. Paus. *Attic.* i. 42), but long afterwards repaired. It presents in consequence a very shattered appearance, and the other colossus gives us a better idea of what the pair must anciently have been. Many Greek and Latin inscriptions on the Vocal Statue record the visits of those who were with Hadrian, and of others, and relate that they heard the voice of Memnon. There is thus satisfactory evidence to show that some sound was frequently heard here at sunrise; and the only dispute is whether it was produced by a physical cause, or was an imposture of the priests. That it was a natural occurrence does not seem impossible from the examples we have of sounds resembling that which is described as having been heard here by the ancients.

Less than half a mile from the mound of the Amenophium, in a south-westerly direction, within the desert, is the group of temples known as those of Medeenet-Haboo. This name is that applied by the Arabs to a town, which appears to be that called Papa in the Roman times. The ruins of its houses obstruct the temples, more especially the larger of the two. The smaller temple is nearer to the river, to the eastward of the other. We first enter a ruined court, which was never completed, and which had a colonnade of which two columns alone yet stand, at its end, a little before the first propylon of the temple, which bears the names of Ptolemy Lathyrus and Anletes among the sculptures of its gateway. Beyond this is a court which had a colonnade on each side, and a propylon, much smaller than the other at the end. Most of its columns have fallen, and the propylon has also suffered much. On the latter we see the names of Taharka, or Tirhakah the Ethiopian, and later sovereigns. Beyond this is another court, and then the chambers of the temple. The chief of these is an isolated sanctuary, with a gallery around it having square pillars and fluted columns like those of certain of the tombs at Beni-Hasan. The sanctuary is ornamented with sculptures of sovereigns of Dynasty XVIII., including Queen Hatshep.

To the south of this temple is a very remarkable structure, which differs from any other ancient monument in Egypt. It is supposed to have been a palace.¹ After passing between what seem to have been lodges, we arrive at the main part of the edifice. This consists of two towers on each side of a court, ending in another tower,

beneath which is a gateway conducting to the great temple. On the front of each of the two towers first mentioned Ramses III. is represented slaying his enemies before Amen-ra, and below is a series of captured chiefs. The inscriptions that remain tell us that these are the chiefs of the Kheta, or Hittites, the Amari, or Amorites, the Takkaru, or Teneirians, the Shardana of the sea, or Sardones, the Tursha of the sea, or Etruscans, and of other peoples. On the walls of the chambers are curious sculptures usually supposed to represent the private life of Ramses III., but probably of a mythological import. Among these the king is portrayed playing at a game like that of draughts with a goddess, while another stands by him.

The great temple of Medeenet-Haboo is directly behind the palace through which was, as already mentioned, the approach to it, and is a monument of the same king, Ramses III., a sovereign inferior alone as a conqueror to Ramses II., the greatest ruler of Egypt. Both the magnificence of its architecture, and the high interest of its sculptures, render it one of the most interesting edifices at Thebes.

The first propylon cannot be less than 200 feet wide. It is partly destroyed, and much of it is hidden by the remains of the town. On its wings the king is represented slaying prisoners before the gods, and acts of worship are also depicted. The court, of which this propylon is the front, is about 110 feet in length and 135 in breadth, and has a colonnade on either side, forming a gallery. The gallery on the right side consists of seven Osiridean pillars, that on the left of eight columns having capitals of the form of the papyrus flower, affording a remarkable example of the irregularity of Egyptian architecture. At its end is a second propylon, on the left wing of which Ramses III. is represented bringing captives of the Takkaru, or Teneirians, before Amen-ra. Passing through the granite portal of this propylon we enter the second or peristyle court, the finest part of the temple. This court measures about 123 feet in length, and about 135 or somewhat more in width, thus exceeding in size the first court, contrary to the usual practice of ancient Egyptian architects. It has a single colonnade at the front and on either side, and a double one at the end. The colonnade at the front and that facing it are each of eight Osiridean pillars, while that behind the latter is of columns with capitals of the papyrus-bud, and the side colonnades consist each of five similar columns, one of which, on the left side, has fallen. The Christian inhabitants of the town, the ruins of whose church are seen in the court, defaced many of the sculptures, and particularly the Osiridean pillars; nevertheless the general effect is not lost, and one is struck by a simple grandeur, which is unsurpassed in any similar Egyptian structure. The sculptures of the wall are of especial interest. On the back of the left wing of the propylon a series of sculptures relating to the wars of Ramses II. begins and extends along the wall on the left side of the court. The rout of the Rebu or Lebu, the Libyans, is depicted, the triumphal return of the king, the bringing of prisoners before him on the field of battle, and the like; and besides these are subjects portraying ceremonies. On the right side-wall is a curious representation of the celebration of the Panegyry of Amen-ra Ka-mut-f, which, from the detail in which it is given, affords us considerable insight into the manner in which such solemnities were kept (*Anc. Eg.* iv. pl. 76). On the end wall, and on part of each side wall, are depicted the many children of Ramses III. A door in the end wall conducts to the inner part of the temple, which occupies but little less space than the two courts just described. It is in a very ruined condition.

¹ The size and character of the only chambers in the temples which could have been used for habitation render it most improbable that any but priests and scribes resided in them; and it is most likely that the royal abodes were usually extensive pavilions constructed of no stronger materials than the houses of the people, and this view the representations of the tombs seem to support. The temples, however, were called palaces.

The sculptures of the exterior of this edifice next claim our attention, none of which have been mentioned except those which occupy the face of the first propylon. On the north-eastern wall is a remarkably interesting series of scenes in the wars of Ramses III., equalling in the importance of their subjects and the boldness with which they are executed any other records of the kind in Egypt. In the first representation, which is to the extreme right, we see Ramses III. going to war; in the second is depicted the rout of the Tamhu, a Libyan people; and in the third, prisoners of the Tamhu and Mashasha, also Libyans, are brought before the king, while scribes count the hands, &c., which have been cut from the slain, showing their number to have been 12,535. Then weapons are counted for distribution to the troops. Then we see troops setting forth. The next scene is a great battle with the Takkaru or Teuerians, whose army is defeated by the Egyptians. The Takkaru fight in chariots of two horses and in waggons drawn by four oxen. Moreonaries or allies of the Shardana, Sardones, fight in the army of Egypt. The scene which follows this is one of the most spirited of Egyptian sculptures, and if compared with similar Assyrian reliefs, shows the great superiority of the best Egyptian art over that of Assyria. The king, who is passing through a marshy country in his chariot, encounters three lions, and having smitten two of them with his javelins, turns round to meet the third which is about to spring. The next subject, the most remarkable of the series, represents the sea-fight, in which the Egyptian fleet defeated that of the Shardana and the Takkaru, while Ramses and his army fought them from the shore. Ramses then receives the praises of his warriors, and the hands of the slain are brought before him and numbered. Next he leads prisoners, who are of the Takkaru and Rebu, before the gods of Thebes. The other battle-scenes of the series represent the capture of strong places, the carrying away of captives, &c. On the end wall the king is portrayed setting forth on an expedition, and on the other side wall, the south-west, is a long calendar, which appears to occupy the whole wall. This temple was no doubt connected in purpose with the royal tomb. Not far from the Ramesseum, to the southward, is a small Ptolemaic temple containing three chambers. Farther in the same direction is a great lake. More than half a mile in a south-westerly direction from the lake is another small temple of Roman times, having an isolated sanctuary and other chambers.

The private and royal tombs must now be briefly noticed, but from their great number, and the variety of the paintings which occupy their walls, it will not be possible to give as detailed an account of them as has been given of the other monuments. Two temples which are situated in the necropolis likewise require a notice. The tombs, as before mentioned, occupy some of the space at the foot of the mountains, or are excavated in their sides towards the valley, and in two isolated hills, except the Tombs of the Kings, which are ent in the sides of two secluded valleys to the westward.

Beginning from the north, we first see the entrances of grottoes in the low spur of the Libyan chain behind the Setheum. Several of these have a series of square apertures, leaving pillars to support the roof, so as to form a kind of portico, behind which is a chamber or chambers, having pits, from which open other chambers for sepulture. Some grottoes here, and others extending towards the Ramesseum, are inhabited by the people of El-Kurnob, whose village is ruined. At the foot of the mountains, as well as on their least steep sides, here and throughout the necropolis, are the entrances of many mummy-pits. On the spur above mentioned are brick pyramids, for the most part nearly destroyed; and in the wide tract beyond, the

Asaseef, where the mountains recede, are very remarkable sepulchres of the time of Dynasty XXVI. These are extensive excavations, profusely sculptured almost entirely with hieroglyphics, having before their entrances open courts hewn in the rock, and entered through crude-brick propyla, from which walls of inclosure of the same material extend around the courts. The largest of these, and indeed of all those known at Thebes, is the tomb of Petamenapt, a priest whose date is not fixed, but who probably lived after the fall of the Ramessides. Sir Gardner Wilkinson says that "the area of the actual excavation is 22,217 square feet, and with the chambers of the pits 23,809, though, from the nature of its plan, the ground it occupies is nearly one acre and a quarter" (*Modern Egypt and Thebes*, ii. 222). Almost all the passages and chambers are covered with hieroglyphic inscriptions on a small scale, and the few sculptures are of a religious character. At the end of the Asaseef is a temple which was approached by a very long avenue of sphinxes now entirely demolished. The temple is at the base of a steep cliff, and is partly excavated in the rock, and partly built of masonry. The built portion is almost wholly destroyed. A portal of red granite which formed its entrance yet remains, bearing the name of Thothmes III., cut over the erased name of Queen Hatsheput. A second granite portal stands behind this, almost close to the rock. At some distance to the left of this are two small chambers, one of which is remarkable for the form of its roof, which is vaulted by horizontal stones, of which the two uppermost meet in the centre, all being cut internally, so as to form an arch. The excavated part of the temple consists of an oblong chamber of moderate dimensions, another of smaller size with a cell on each side, and at the end a sanctuary. All these, except the sanctuary, are of the time of Queen Hatsheput and Thothmes III., and have vaulted roofs. The sanctuary bears Ptolemaic sculptures, affording a remarkable contrast to the delicate style of those of the chambers which lead to it, and it is flat-roofed. This temple was probably sepulchral.

The isolated hill of the Shoykh 'Abd-El-Kurneh (probably a mistake for 'Abid-El-Kurneh, meaning "the Devotee of El-Kurneh"), presents a singular appearance from the plain, as on that side it is honeycombed by the entrances of tombs. Several of these, like some of those first mentioned, have porticoes before them hewn in the rock, and many have very interesting paintings, representing scenes of domestic life, funeral ceremonies, arts, trades, &c., in their chapel or chapels. These have unfortunately suffered greatly from the disgraceful Vandalism of European travellers, and the cupidity of the natives which they have encouraged. Farther towards Medeenot-Habeo is a similar isolated hill, called Kurnet-Mara'ee, which contains a few grottoes of the same description, and in the valley between this and the main mass of mountain are many other interesting grottoes. At one extremity of this valley, at some distance behind the Ramesseum, is a small edifice with a high inclosure of crude-brick walls. It is a temple of Athor, of the Ptolemaic period, and has a small portico and three chambers, in one of which, the side chamber to the left, is a curious sculpture, of which the subject is the judgment of a soul by Osiris. Hence we may infer that this was a temple attached to the necropolis. Beyond the other extremity of this valley is the secluded valley called that of the Tombs of the Queens, from its containing the sepulchres of queens and princesses of Dynasties XVIII., XIX., and XX. These are similar to the Tombs of the Kings, but are not large, nor are the subjects on their walls, which seem generally of little interest, well preserved.

A long and winding valley, the entrance to which is an

opening in the mountains behind the Setheum, leads to two other valleys, that of the Tombs of the Kings, and the Western Valley. Both these contain royal sepulchres, but those of the former are the more important. The sepulchres in the Valley of the Tombs of the Kings are twenty-five in number. Nineteen are the mausolea of kings, of a queen with her consort, and of a prince, all of Dynasties XIX. and XX. One tomb is without sculpture, and there is likewise an unsculptured passage running for a considerable distance into the mountain, which may be regarded as an uncompleted tomb. M. Mariette has found the tombs of functionaries in this valley (*Mon.*, 234). Their plan is always the same in its main particulars, but they differ greatly in extent, in consequence of having been begun at a king's accession, or even before (for one of them is the tomb of an heir-apparent), and continued throughout his reign, like the pyramids of Memphis. Their paintings and painted sculptures likewise do not present remarkable varieties, for they are almost wholly of a religious character, and principally refer to the future state. These subjects are taken from the Book of the Lower Hemisphere, treating of the course of the sun in the twelve hours of the night, and so in the nether world. They are interesting for the manner in which they illustrate the Egyptian religion, and for the beauty of their execution; but their intricate nature forbids any detailed description of them in the present article. The plan of one of the most interesting sepulchres may, however, be described. The tomb of Setee I., commonly called Belzoni's, since that explorer first opened it since ancient times, is in the freshest state of preservation, except in its outer part, although the miserable barbarism of modern travellers is yearly lessening its beauty. We enter by a staircase, and pass along a steep passage, which ends in a deep pit, now filled up. Thus far the subjects and inscriptions which occupy the walls are unfinished, showing that the tomb was not completed. Immediately beyond the pit, the part discovered by Belzoni begins with a hall 26 feet by 27, supported by four square pillars, the walls of which are covered with very beautiful painted sculptures, including the celebrated procession of the four races. To the right of this is another chamber, supported by two columns, the decorations of which were never begun, having only been drawn in outline. From the left side of the former chamber we descend a flight of steps, which leads to a passage, another flight of steps, and then another passage, ending in a chamber 17 feet by 14, from which we pass into a hall 27 feet square, having six square pillars, and on either side a small chamber. This forms the portico of the great sepulchral hall, the most splendid part of the tomb, which is of an oblong form, 19 feet in length and 30 in breadth, with an arched roof. In the midst, in a depression, was a splendid sarcophagus of alabaster, now in the Soane Museum, and on its removal blocks of stone were found filling up the entrance of an inclined descent, which was cleared for 300 feet by Belzoni, without its termination being discovered. It is not impossible that the king was buried in a chamber at the end of this passage. The great sepulchral hall is covered with beautiful painted sculptures, and on its ceiling are astronomical or astrological representations, resembling the astronomical ceiling of the Ramesseum of El-Kurneh. A door in the left side of the sepulchral hall leads to a chamber which has two square pillars, and on the same side is a cell; there is another chamber on the opposite side. A large apartment, which was left unfinished, is behind that in which was the sarcophagus, and is the last of those contained in the tomb, if the inclined descent does not lead to other unknown ones. From the entrance to the end of this chamber is a distance of about 300 feet.

The tomb of Rameses III. is among the most splendid of the royal sepulchres. Its length a little exceeds 400 feet, but from the nature of the rock its sculptures are less delicately executed than those of the tomb of Setee I. In cells on either side of its passage, a little within the entrance, are interesting paintings illustrating manners and customs, in one of which is the celebrated representation of the harpers.

The tombs which have been found in the Western Valley are only four in number, and but two of these contain paintings, those of Amenophis III. and of King Ai, the sun-worshipper who succeeded Khu-naten. The former is decorated with paintings in a very good style, but unfortunately they have sustained much damage; the latter is historically interesting as a record of an obscure king, but its paintings are of poor execution.

Nowhere, perhaps, are we so forcibly struck by the feeling of the ancient Egyptians with respect to death and the future state as in the Valley of the Tombs of the Kings, and in the sepulchres themselves. The desolateness of the spot, apart from all signs and sounds of life, fitted it for the solemn use to which it was assigned; and those long dark passages, and lofty chambers, on whose walls we see the awful punishments of the wicked and the rewards of the good, fitly unveil the most secret mysteries of the Egyptian religion.

Not far south of Thebes, on the western bank, is the large village of Arment, the old Hiermonthi, where stands a picturesque temple built by Cleopatra. It has two courts with colonnades, and three chambers around which was also a colonnade, of which but one column now stands. It is of small dimensions, having been the "Typhonium" attached to the great temple of Mentu, the divinity of the place, which has been razed. On the other bank of the river, a little higher, at Tôd, anciently Tophium, is a small Ptolemaic temple. Not far beyond, and about 20 miles above Thebes, by the course of the stream, are the "Gebelcyn," or "Two Mountains," on the western side of the river, where the sandstone begins. The town of Isnè, the ancient Snc, called by the Greeks Latopolis, is likewise situate on the western bank, about twelve miles higher, and is remarkable as containing a very fine Egyptian monument, the portico of its great temple of Kneph. This is in the heart of the modern town, and was much choked with rubbish until cleared by Mehemet Ali. It is supported by twenty-four lofty and massive columns, six in front, and four deep, having capitals of various forms, of which those alone in corresponding positions on opposite sides are of the same description, a deviation from regularity of which we do not see examples previous to the Greek rule. The columns and walls are covered with minute sculptures of the bad style of the period when the portico was erected.—that of the Cæsars. It contains the hieroglyphic names of Claudius, Vespasian, Titus, and other emperors as late as Severus. The back is, however, more ancient, for it bears the name of Ptolemy Philometer, being the front of the older temple of which nothing more is known for certain to remain. Upon the ceiling is a zodiac, from which this monument was supposed to have been of very great antiquity before the interpretation of hieroglyphics had been discovered. On the other bank of the Nile, on the site of Contra Latopolis, is a small temple of the Ptolemaic and Roman periods.

A few miles above Isnè, where both the Libyan and Arabian chains approach the river, are the curious remains of Eilethya (so written in Egyptian geography). There is a small temple of the Ptolemaic time, and two little sacred edifices of the period of the Pharaohs, but the most interesting monuments are the tombs and the fort. The former, which are excavated in a hill, are very remark-

able as illustrating history as well as everyday life, husbandry, &c.; and in one of them is the very curious inscription of its occupant Ankhnes, chief of the mariners, recording his services to early kings of Dynasty XVIII. The fort is a large inclosure of crude-brick,¹ which was a place of importance as early as the Shepherd war, for it is mentioned as the "Fort of Subeu," that is of Eleithyia, in a part of the inscription above mentioned, relating to the time of that war. The goddess of the place was Suben or Lucina (Eleithyia), who was especially regarded as the protector of Upper Egypt.

Having proceeded about twelve miles to the southward we reach the large village of Adfoo or Edfu, which represents the town called by the Greeks Apollinopolis Magna, the great temple of which yet stands in a comparatively perfect state, and is one of the most stately monuments of ancient Egypt, although of a time at which art had greatly declined. It was dedicated to Har-hut, the god of the place, whom the Greeks called Agathodaemon. Mounds of rubbish around it, as well as the huts of the village, injured its effect, until it was lately cleared by M. Mariette.

The great propylon which forms the front of the temple measures about 226 feet in width, and is, like the rest of the edifice, in a good state of preservation. The sculptures upon its face represent acts of worship by Ptolemy Auletes, who is portrayed slaying prisoners.

The portal between the wings of this propylon is the entrance to the temple, of which the first part is a great court about 161 feet long and 140 broad, with a colonnade along its front and each side, of columns with various capitals supporting covered galleries. At the end is a portico having eighteen columns, six in front and three deep, about 82 feet broad and 46 long, measured within, beyond which are a hall and passages and other chambers, the most important of which is an isolated sanctuary. The wall of the great court is continued so as to inclose the further portion of the temple, leaving a passage around it. The sculptures show that it was begun by Ptolemy Philopator and completed at the end of the Greek monarchy, though an insignificant additional subject was added by Claudius. Not far from the great temple is a smaller one of the sort called Typhonion, containing two chambers, around which runs a gallery supported by Typhonian columns.

About twenty-three miles above Adfoo the mountains on either side, which had for some distance confined the valley to a narrow space, reach the river and contract its course. They are low, but steep and picturesque, and in their western side are seen the entrances of excavations. They are called Gebel-es-Silsileh, a name derived from the earlier Silsilis. The most interesting of the excavations is a rock-temple in which is portrayed the defeat of a negro nation by King Har-em-heb, or Horus, of Dynasty XVIII., here, also, are subjects depicting acts of worship paid to Nilus and Sebek. To the southward of this, and also facing the river, are the entrances of several excavated tombs, the representations in which are not of a remarkable character. Beyond these are three chapels of the time of Dynasty XIX. On the opposite side are very important quarries, where much of the materials of the great temples was cut, especially under the Eighteenth and subsequent Dynasties.

Beyond Gebel-es-Silsileh, although the mountains recede, the tract of cultivated land is extremely narrow, and sometimes the desert touches the river: this is partly owing to the sinking of the level of the stream, which, as already mentioned, was very anciently restrained by some barrier at Silsilis. About eleven miles above that place is the

extremely picturesque temple of Ombos, placed on a rocky eminence called "Kôm-Umboo," "the Hill of Umboo." It stands within a great inclosure of crude-brick walls, which we see on every side, except that towards the river. There is a portal in this wall of the time of Queen Hatshepsut and Thothmes III. The great temple is double, one-half having been dedicated to the worship of Sebek, and the other to that of Har-oer, or Aroeris. It consists of a portico of fifteen columns, of which two have fallen, the foremost being connected by a wall of intercolumniation having two entrances, and behind, there is a smaller portico and remains of chambers, including the two sanctuaries. The earliest name here is that of Ptolemy Philometor (*Modern Egypt and Thebes*, ii. 282), unless Champollion be right in saying that the name of Epiphanes is also found in the temple (*Lettres*, 173), and it appears to have been completed by Ptolemy Auletes. There were also remains here of a smaller Ptolemaic temple which have been washed away by the river.

Nothing remarkable occurs between Ombos and Syene, a distance of about twenty miles. The valley is confined to a very narrow space by the mountains, which take bold forms on both sides near the latter place. Just before we reach it, we see the island of Elephantine, where is the famous Nilometer of the Roman time. The town of Aswân, which represents the ancient Syene, stands amid palm-trees on the eastern bank opposite to Elephantine. It is a considerable place, of greater political than commercial importance, and has succeeded to an older town of the same name, the ruins of which occupy the river's bank and a granite hill to the south. Among them may be mentioned a pier, which has a well, most probably the Nilometer constructed by Amr, the Muslim conqueror of Egypt. In the ruined town is also a small temple of Roman date. Farther to the south is its extensive Arab cemetery, which is full of curious tombstones bearing inscriptions in Coptic characters. In the granite hills to the eastward are the quarries whence were taken the obelisks and very many of the statues which adorned the Egyptian temples.

The bed of the river above Aswân is obstructed by numerous rocks and islands of granite, one of the latter of which, that of Saheyl, is interesting on account of the numerous hieroglyphic tablets and inscriptions at its southern part. This island is almost a mile and a half above Aswân, and at the distance of another mile from it begin the rapids called the First Cataract, caused by the granite rocks, which almost entirely choke the river. The cataract is so inconsiderable, that during the inundation boats favoured by a strong northerly wind can pass it without aid, though at other times it is necessary to hire natives, who drag them through, but then the principal rapid has a fall of only five or six feet (*Modern Egypt and Thebes*, ii. 294), and that is not perpendicular. Nevertheless the roaring of the troubled stream, and the red granite islands and rocks which stud its surface, through which the boat threads its way, give the scene a wild picturesqueness, until we reach the open stream, less than two miles farther, and the beautiful isle of Philæ suddenly rises before the eyes, completely realizing our highest idea of a sacred place of ancient Egypt.

Philæ is beyond the proper limits of Egypt, but as it is usual to describe it in noticing Aswân and the rapids, some account will here be given of its very beautiful and interesting monuments. The island is very small, being only a quarter of a mile long, and about 500 feet broad. On its granite rock is a little alluvial soil and some vegetation, with a few date-palms, but its verdure has been exaggerated, and to this it little owes its beauty. It was highly revered by the ancient Egyptians as a burial-

¹ For an account of the Egyptian system of fortification, see Wilkinson in *Trans. Soc. Lit.*, n. s., iv.; and *Popular Account of Ancient Egyptians*, i. 407-409.

place of Osiris. On the east side is a small but very picturesque temple, now hypæthral, of the Greek and Roman time, and unfinished. It is 48 feet in width and 63 in length, and has 14 columns with capitals of various forms, connected by intercolumnal walls. The great temple of Isis stands to the westward of this. Its front is formed by a propylon, before which is a kind of court, to be afterwards described. The portal bears the name of Nectanebes II., but the wings were added by the Ptolemies, making the entire width about 122 feet. Through the portal we enter a court, on the right side of which is a gallery fronted by columns, behind which are several small chambers, and on the left side is a separate small temple of Athor, the main entrance to which is by a door and passage in the left wing of the great propylon. This small temple begins with a portico having four columns with the faces of Athor sculptured in high relief upon each of their sides above the capitals. Beyond this are three chambers behind one another, above the door of the first of which is a Greek dedication by Ptolemy Euergetes II., and the two Cleopatras. The temple was, however, begun by Epiphanes. The court of the great temple, that of Isis, is bounded by a second propylon of smaller dimensions than the first, forming the entrance to the portico, which is a very elegant structure raised on ten columns, eight of which are at the back and one on each side. It is partly hypæthral, an open space being left between the two columns last mentioned. The beautiful forms of the columns and the bright remains of colour on them and the walls, with the effect of the sunlight through the aperture of the roof, produce a charming effect. Behind this hall are several small apartments, one of which, reached by a staircase, contains very curious sculptures relating to the story of Osiris. The temple appears to have been begun by Ptolemy Philadelphus (whose name is the earliest found there), and was continued under the Roman emperors. The court before the temple remains to be noticed. It is bounded by two galleries with columns in front. One of these is about 250 feet long, and is built close to the western side of the isle, terminating at a small temple of Athor near its southern end. This edifice, which is much ruined, was supported by columns with faces of Athor above their capitals, of which six stand; it was raised by Nectanebes II. The eastern gallery, which is shorter than the other, is not parallel with it, and thus shows that this court was not part of the great temple, but rather an approach to it. The other remains are of minor importance, and the same may be said of the ruins of a temple on the neighbouring large island of Bigé.

A few words must be said respecting the eastern and western deserts. The latter is remarkable for two valleys besides those called the Oases. The first of these valleys is that of the Natron Lakes to the westward of the Delta, containing four monasteries, the remains of the famous anchorite settlement of Nitria. To the southward of this, and parallel to it, is a sterile valley called the Bahrela-Ma, or "River without Water." Yet farther to the southward is the Little Oasis (Oasis Parva), about 100 miles from the Nile in 29° E. long., nearly due west of the town of Bahnesé. It contains remains of little interest. Within 200 miles due south of this oasis is another, of which the usual appellation is Wâh ed-Dâkhileh, where, near the town of El-Kasr, is an Egyptian temple of the Roman period. This, according to Sir Gardner Wilkinson, is the most flourishing of the oases. About half-way between this oasis and the Nile at Thebes lies the Great Oasis (Oasis Magna). Here, near the town called El-Kharigeh, the ancient Hibe, is a great temple of Amen built by Darius I., and in the same oasis are other ruins of the period of the Ptolemies and Cæsars. The Oasis of

Jupiter Ammon, that of Seewah, is not far from the coast at a great distance to the westward, and it is not properly included in Egypt. Various Arab tribes occupy this desert, besides the settled inhabitants of the oases.

In the eastern desert must be mentioned the town of Es-Suweys, or Snez (15,000 inhabitants), anciently Arsinoë, at the head of the gulf to which it gives its name. To the southward, a little below 29° lat., are the secluded Coptic convents of St Antony and St Paul, near the sea. Farther south are the porphyry quarries of Gebel-ed-Dukhân, extensively worked under the Romans, and the granite quarries of Gebel-el-Fateereh. Considerably more to the south, at El-Hammâmât, on the old way from Coptos to Philoteris Portus, are the Breccia Verde quarries, which were much worked from very early times, and have interesting hieroglyphic inscriptions. At Gebel Zabarah are emerald mines, now abandoned as unproductive. At the various mines, and on the routes to them and to the Red Sea, are some small temples and stations, ranging from the Pharaonic to the Roman period. Along the shore of the sea are the sites of several ancient ports, the most important of which were Myos Hormos and Berenice, and also the modern town of El-Kuseyr. The northern part of this desert is occupied by the Ma'azee Arabs and smaller tribes as far as the Kuseyr road, beyond which are the 'Abâbdeh, an African tribe very different from the Arabs in appearance; and to the south of these, to the east of Lower Nubia, is the Bisharee tribe, a people also of African race.

STATISTICS.¹

[In Egypt, as has been well said, *L'État c'est le Khedive*. So far as the country itself is concerned the khedive is its personal, absolute, and independent sovereign; but his relations with the Porte are somewhat less simple. When Selim I. of Turkey conquered Egypt at the beginning of the 16th century, the Memlook power was still too strong for complete subjection, and Selim was obliged to allow his new subjects liberal terms. Egypt still retained practical autonomy, the government being in the hands of a council of Memlook beys, presided over by a pasha, whose duty it was to look to the annual tribute paid to the Porte, but who possessed little or no actual power. This system was continued till the French occupation, and was re-established when the English army evacuated the country. The Memlooks were still the virtual governors of Egypt, until their massacre by Mehemet Ali. The ambitious designs of this pasha opened the eyes of the Porte to the dangers incurred by so lax a control of a governor unshackled by the council of beys. Menaced with the loss of Syria as well as Egypt, the cause of the sultan was espoused by four of the Great Powers; and the Treaty of 1840, confirmed by the Convention of 1841, limited Mehemet Ali's power to the vice-royalty of Egypt, hereditary by the eldest male of his family, ordered the continuation of the customary tribute, restricted the military and naval strength of the viceroy, and imposed certain other conditions, thus reducing Egypt once more to the state of a Turkish province. But in the reign of the present ruler a change has taken place in the relations between the sultan and his viceroy. A series of expensive negotiations with the Porte, ending with the raising of the tribute from £376,000 to £675,000, procured for Ismail Pasha the title of Khedive, and the right of succession from father to son. The limitation of the Egyptian army

¹ For much of the information contained in the present section, the writer is indebted to the industrious work of Mr J. C. McCoan, *Egypt as it is*, though he has thought it necessary to check it with official reports and other authorities: but it must always be remembered that Egyptian like all Oriental statistics can be accepted only with reserve.

and other restrictions which still remained were removed in 1872 by another firman, confirming all the rights previously granted, and giving the khedive every substantial attribute of sovereignty, except only the *ius legationis*. The khedive is therefore virtually an independent sovereign, holding his power on the easy tenure of tribute and military aid in case of war.

The real work of governing is entirely performed by the present energetic and able sovereign. The merely formal business is transacted by a Privy Council and eight ministers—the agents, not the rulers, of the khedive. The Privy Council, presided over by the Prince Héretior Mehmet Tawfik Pasha, and consisting of the ministers, the Sheykh el-Islâm, and some other functionaries, examines and reports to the khedive on the work of the several departments. The eight ministries are those of (1) Finance, (2) Foreign Affairs, (3) Interior, (4) War, (5) Marine, (6) Commerce, (7) Public Works and Agriculture, and (8) Public Instruction. Besides these there are the sub-departments of the Customs and Post-Office.

The provincial administration (exclusive of the separate governors of the eight "cities") is divided among the muders of the fourteen prefectures, the Foyoom now being one, each subdivided into departments and communes, or cantons including several villages, governed by ma moors, nazirs, or sheykhs el-beled, appointed by the Government and assisted and checked by councils of agriculture and an administrative council for each canton.

In 1867 the Assembly of Notables was revived, consisting of village sheykhs, &c., elected by the communes and meeting once a year to receive from the Privy Council a report of the twelve-month's administration. Although the Assembly has not yet attained to the full dignity of parliamentary power, it has considerable weight in the control of state measures.

By the Convention of 1841 the Egyptian army was limited to 18,000 men, but this was raised to 30,000 by the firman of 1866, and now all restrictions have been done away. The present force may be placed at an average peace strength of 30,000 men, regulated, however, on a short service system, so that not more than half this number are generally at one time with the colours. This army consists of 18 regiments of infantry, 3 battalions each; 4 battalions of riflemen; 4 regiments of cavalry, 6 squadrons each; 4 of field artillery, 6 batteries each (2 mounted); 3 of garrison artillery; and 3 battalions of pioneers. The infantry are armed with the Remington rifle; the cavalry with revolver and lance, or sabre and carbino; the field artillery with 100 Krupp guns and 50 smooth-bore. Besides these there is a reserve of 30,000 men, and an irregular contingent of 60,000 mounted Bedaweess. The army is raised by conscription, irregular levies being held every two or three years. All Egyptians of any creed are liable to conscription, except only the inhabitants of Cairo and Alexandria; but immunity may be purchased by payment of a tax. The monthly pay ranges from 20 piastres (= 4s. 2d.) for a private, to £5 (Egyptian) for a captain, £40 for a full colonel, and £75 for a full general. Under the training of French and American officers, the army has been brought into an admirable state of discipline and efficiency.

The Egyptian navy hardly deserves notice. It consists at present of 2 frigates, 2 corvettes, 4 gunboats, and 2 sloops, all unarmoured.

Mehemet Ali devoted considerable attention to the establishment of colleges and military schools, besides sending young men to Europe for purposes of scientific study. In Cairo and its environs he founded several elementary schools of a higher order than the native schools of the same class; a school of languages; a printing press at Boolak, from

which many valuable publications have issued; and a school of medicine at Kasr-el-Eynce, between Cairo and Masr-el-'Atokah, which has done excellent work. At El-Khankah and in its neighbourhood he placed a military hospital, a school of medicine, a veterinary college, an infantry school, and a school of music; at El-Geezeh a cavalry school; and at Turâ one of artillery. These and similar establishments were well designed and ably carried out. When Mehemet Ali's ambitious designs were defeated in 1840 by the action of the Powers, his educational reforms languished, and under 'Abbas the schools were closed and everything returned to the old system. Said Pasha endeavoured to revive Mehemet Ali's improvements; but it was reserved for the present khedive entirely to carry out his grandfather's designs. Besides the revived and newly created military schools, there are two systems of education in Egypt—by the schools established and supported by the Government, and by the old system of mosque education and Arab primary schools,—besides the numerous establishments of the non-Muslim communities. The Government schools are nine in number—the Polytechnic, Book-keeping and Surveying, Law and Languages, Industrial, Medical, Midwifery, two preparatory schools at Cairo, and one at Alexandria. Besides these the Government supports a school for the blind, a normal school, two girls' schools, three industrial schools, and 23 municipal schools. At the Polytechnic School the course extends over six years, and includes the higher mathematics, chemistry, physics, geology, mechanics, geography, history, drawing, Arabic, and English or French.

Of the mosque colleges, the greatest, not only in Egypt but in the whole Mohammadan world, is the Azhar, where over 11,000 students, coming from every quarter of the Muslim empire, are instructed by 325 sheykhs in the old curriculum of Muslim acquirement. The Arab primary schools, 4000 or 5000 in number, are the regular providers of education for the fellâheen, who pay either nothing at all, or a merely nominal sum, for being taught to read and recite the Korân, and sometimes writing and very elementary arithmetic. How greatly the educational system in Egypt has been enlarged of late years may be judged from the fact that, under Said Pasha it hardly cost the Government £4000 a year, whilst the educational budget (exclusive of the military schools) now reaches the sum of £40,000, to which the khedive adds £12,500, making a total of £52,500.

Of the schools of non-Muslim communities the Copts have 16, the Greeks 4, the Armenians 1, and the Jews several academies. Besides these there are two undenominational "Universal Schools," of foreign foundation, where a moderate education, without religious instruction of any kind, is given to all comers, and many schools founded by the American Board of Missions, and Miss Whately's admirable British Mission School. The proportion of girls' schools is extremely small, but their existence, and the fact that they receive the warmest support of one of the wives of the khedive, is a hopeful sign.

The public works carried out in Egypt during the present reign would fill a long catalogue, without reckoning the Suez Canal, for an account of which see CANAL, vol. iv. p. 789. Railway communication has been established between Alexandria, Cairo, Ismaïlia, Suez, Damietta, the Foyoom, and Asyoot, the various lines covering over 1200 miles. A Soodân railway, from Wadec Halfeli to Hannok, and from near Dunkalah to Khartoom, involving costly and difficult engineering for a length of more than 1000 miles, has been begun with the view of shortening the passage to India, and bringing the produce of the rich southern soil into easier connection with Cairo; these works are, however, at present at a standstill. The canal

system has been greatly enlarged and improved, but a still better result is anticipated from the barrage of the Nile, a plan projected by M. Mongel and now about to be carried out for the khedive by Mr Fowler. In 1871 the work of building a breakwater to defend the New Harbour at Alexandria from the seas caused by the constant south-west winds was begun. The outer breakwater extends above two miles across the month of the harbour, inclosing an area of 1400 acres of calm water. The structure rises 7 feet above the highest sea-level, and is of a uniform width of 20 feet. Harbour works have also been constructed at Suez. At a cost of over £180,000, fourteen fine light-houses have been erected, seven on the Mediterranean and seven on the Red Sea, whereas at the beginning of the reign of the khedive there was but one. Telegraph lines (begun by the enterprise of Said), have been set throughout Egypt, covering nearly 6000 miles, and putting Alexandria into direct communication with Khartoum; and this branch of the public service is managed by English officials. Submarine telegraphs also bring Egypt into communication with Caudia and thence with Constantinople and Otranto, and with Malta and thence with England, France, &c. The post-office was bought by the Government in 1865, and under the management of an English post official has been greatly improved. In about 70 towns and villages offices have been established, and several mails a day are despatched from the chief places.

The manufactures of Egypt have been in a declining state for several centuries. Mehemet Ali tried to promote them, by establishing large manufactories of cotton, silk, and woollen goods, tarbooshes, &c., and, especially in Upper Egypt, sugar-refineries. Ibrahim Pasha was much opposed to his father's policy, and in pursuance of his own views he laid out extensive plantations of olive and other trees, erected powerful steam-engines for the irrigation of his lands, and on all his estates endeavoured to encourage agriculture. It cannot be doubted that had he lived the correctness of his conviction that Egypt is an agricultural, not a manufacturing, country would under his rule have been fully verified. Mehemet Ali introduced cotton and largely cultivated it; the Turkish grandees found that from it they could extract more gain than from other field produce, and large tracts were speedily devoted to its culture. The necessity, however, of excluding the waters of the Nile has caused several destructive inundations, and so long as the cotton growth remained a monopoly of the pasha it was no means of enrichment to the producer. Now, however, that the monopoly is abolished, the trade in cotton is greatly increasing, and this produce will undoubtedly become every year a more important item in the wealth of the country. The old restrictions upon agriculturists have been more or less done away; and the Government, whilst not wholly abandoning Mehemet Ali's views on manufactures, is yet alive to the paramount importance of affording every encouragement to agriculture.

The cotton crop in 1875 extended over 871,847 feddâns (= acres, nearly) and produced 2,615,541 quintals (of 110lb) of ginned staple, 1,954,555 ardebbs (of 5 bushels) of seed, and 3,749,446 loads of cotton sticks, altogether reaching a total value of about twelve millions and a quarter. The wheat crop in the same year was estimated at 6,662,632 ardebbs, of the value of £27,995,158; maize (durah), 10,502,715 ardebbs, = £28,193,000; beans, 4,575,273 ardebbs, = £24,575,273; barley, 3,103,085 ardebbs, = £22,394,000; rice, 98,521 ardebbs, = £2738,908. The other crops of Egypt are chiefly clover, sugar-cane, flax, hemp, tobacco, henna, and indigo.

The revenue is derived chiefly from the land-tax, the tax on date-trees, trade licences, the customs, the tobacco duty, railways, and the Mnkabalah (of which an account will be given), and village annuities. Of these the land-tax is the principal item, amounting to nearly half the total revenue, but this will be considerably reduced when the Mukabalah

comes to an end (in 1885). The whole revenue may at present roughly be placed at £10,500,000. It is very difficult to estimate the exact amount of direct taxation on the population. One writer places it at 25s per head per annum, whilst a recent report states that, including the Mukabalah, the annual payment of taxes has lately reached £41. It is certain the taxation at present exceeds the possible returns of the land, and that the fellâheen are compelled to borrow money to pay the taxes. The items of expenditure may thus be roughly summarized:—general public administration, £1,300,000; civil list, £600,000; tribute to the Porte, £700,000; army, £700,000; the rest being devoted to the payment of the debt.

The following is an abridgment of the Egyptian budget for 1876 —

Revenue.	Purses.
Land tax	839,500
Tax on Date-trees	36,934
Licences	82,346
Mnkabalah	314,858
Customs	124,737
Railways	193,207
Locks, ports, &c.	32,313
Salt	50,000
Tobacco	51,483
Octroi, various duties, &c.	345,276
Soodân revenues	30,000
	<hr/> 2,100,654
Expenditure	Purses
Tribute to Constantinople	133,635
Civil list of the Khedive	60,000
Allowance to the Prince Hérétier	6,000
Allowance to Halim Pasha	11,700
Appointments of the Cabinet Ministers, &c.	219,156
Various pensions and other expenditure	73,518
Conseil d'Etat, Court of Appeal, Court of First Instance at Cairo, and Chamber of Notables	3,242
Irregular troops	5,792
Egyptian Museum, Ismailia Canal, Archives, Provisions, Stores, &c.	6,633
Customs	5,823
Foreign Agents	2,881
Appointments and expenses of the Provinces of Upper and Lower Egypt	36,546
Appointments and expenses of Cairo, Alexandria, Damietta, Rosetta, Suez, &c., with Octroi	79,304
Expenses of the Rooznâmeh	38,989
Locks, barrages, Soodân Railway, &c.	48,531
Interest on Rooznâmeh Bonds	18,000
Interest on Suez Canal Shares	19,500
Annuities and loans (redemptions and interest)	982,151
	<hr/> 1,751,451

During the last fifteen years Egypt has acquired the enormous national debt of about £80,393,000. The attempt to Europeanize the country has entailed a vast expenditure. Public works have been carried out at an altogether unnecessary rate of speed, and European contractors have been employed who have not scrupled to drive bargains exceedingly favorable to themselves and ruinous to the Egyptian Exchequer. To these causes of expenditure must be added the dishonesty and extravagance of the Government officials, the waste of money on works which have proved unproductive and useless, and the heavy damages given against the khedive in the extraordinary award of the late emperor Napoleon as arbitrator in the dispute with the Suez Canal Company. To meet the heavy expenses resulting from these causes, five loans have from time to time been raised.

The first was borrowed by Said Pasha in 1862, and amounted to only £3,292,800 nominal, to be repaid in thirty years, interest 7 per cent., and sinking fund 1 per cent. The present viceroy then raised the 1864 loan of £5,804,200 nominal, with interest and sinking fund at 7 and 8 87 per cent., redeemable in 15 years. The next loan, of 1868, redeemable in 1898, was for £11,890,000 nominal (of which only £7,193,334 was received), with apparent interest and sinking fund of 7 and 1 per cent., really 11 56 and 1 68 per cent. on amount received, or altogether 13 1/2 per cent.

annual charge. The loan of 1873 was for the nominal amount of £52,000,000 at 7 and 1 per cent. interest and sinking fund; but, as only £20,062,658 was received, the interest and sinking fund became really 11 and 1.62 per cent. The actual amount received was, however, slightly increased by part being paid in Egyptian Treasury bonds. Besides these, in 1866 a railway loan had been raised, of the nominal amount of £3,000,000 at 7 per cent. This was repaid in 6 annual instalments of £500,000 each, the last being in January 1874. Two loans secured on the Daira estates of the khedive have been transferred to the state for value received; these are the Anglo-Egyptian loan of 1865 for £3,000,000 at 9 per cent interest, with sinking fund of 3.27 per cent., and the Mustafa-Pasha loan of 1867 for £2,080,000 at 9 and 3.4 per cent interest and sinking fund. The khedive raised also a personal loan secured on his private estates (Daira) in 1870; £5,000,000 was received, for which £7,142,860 was to be paid back in twenty years, with interest at 7 per cent on this nominal amount. "None of the Egyptian loans," Mr Cave observes, "cost less than 12 per cent. per annum, while some cost more than 13½ per cent. per annum, and the railway loan even 26.9 per cent. per annum, including sinking funds."

These loans hardly sufficed to meet the necessities for which they were raised, and the exorbitant interest charged on the nominal sums, of which the khedive received little more than half, effectually crippled the resources of the country. In 1871 another fatal step was taken. A measure was passed by which a landowner might redeem half his land tax in perpetuity by paying six years' tax in advance, either in one payment or in six yearly instalments. As, however, few but the wealthiest proprietors could afford this additional charge on their incomes, the six instalments were commuted into twelve, a discount of 8½ per cent. being allowed on each instalment. This composition tax is called the "Mukabalah." By this measure the Government, for the sake of the immediate possession of about £27,000,000, will sacrifice from 1885 onwards about £2,500,000 annually of certain revenue. For the over-taxed fellâheen the change is most advantageous, if only they can avail themselves of it; for the Government it nearly resembles suicide.

In 1875 the khedive procured a temporary respite from his difficulties by the sale of the Suez Canal shares to the British Government; and then, at last aware of the critical state of his finances, and of the incompetency of Easterns to mend it, His Highness requested the British Government to provide him with some experienced financier to carry out a thorough reform. In December the Right Honourable Stephen Cave, M.P., accompanied by Colonel Stokes, R.E., and clerks, was sent out, and after some months' examination wrote an elaborate report on the Egyptian finances. But after Mr Cave's departure, and the publication of his report, Egyptian credit fell still lower, till in 1876 the khedive, finding himself totally unequal to meet the demands of his creditors, and weary of renewing bonds at ruinous rates, suspended payment for a time. A French scheme was then urged upon him with so much insistence that on May 7 he adopted it in a decree which announced the consolidation of all the state and Daira loans, and the distribution of a bonus of 25 per cent. to holders of treasury bonds. These bonds had then reached a sum exceeding £20,000,000, and were held chiefly by French firms. The arrangement speaks for itself. It was immediately quashed by the firm action of the English Stock Exchange; and the Right Honourable G. J. Goschen, M.P., and M. Joubert were sent out to attempt the adjustment of the affairs of Egypt. The result was a scheme which the khedive accepted, and which may shortly be described as follows: the private Daira debt was separated from the state debt; the three small loans of 1864, 1866, and 1867 were reserved to be paid off by the Mukabalah; the bonus on the treasury bonds was cut down to 10 per cent.; and £17,000,000 was converted into a preference stock, secured on railways and harbour dues. The state debt was thus divided into three classes:—unified debt of £59,000,000, interest per cent., reduced till 1885 by

a sinking fund of 1 per cent; preference stock, £17,000,000, interest 5 per cent.; and the three short loans, interest 7 per cent., redeemable at 80 instead of 100, and to be paid off by the Mukabalah. Besides these, there is the private Daira debt of the khedive. The scheme is perhaps the best that can be devised under the present perplexing conditions; and if the Egyptian Government can maintain its revenue and will hold to its engagements there is every probability that the debts will be paid off at the appointed times. When the Mukabalah falls in in 1885 the three short loans will (presumably) have been paid off. The preference debt is to be redeemed in 65 years by the operation of a sinking fund of £35,744 a year, and the unified debt in the same time and after a similar manner. With a view to insure the carrying out of these reforms, the khedive has appointed English and French comptrollers-general, who are intrusted with the collection of the revenue and the appropriation of it to the purposes settled by the financial scheme. A European Commission of the Public Debt has also been appointed for receiving the revenue devoted to the payment of the debt charges; and another commission, composed of three Europeans and two natives, controls the railways and the port of Alexandria. So long as the present arrangement is held to, and if no unforeseen decrease takes place in the revenue, the financial position of Egypt may be considered hopeful. The khedive has been the subject of much censure at the hands of his bondholders. It must however be remembered that he received but half of the sums supposed to have reached him. Of the £45,000,000 received he has paid back over £30,000,000 in interest, &c., and £10,000,000 went in the Suez Canal indemnity, so that only £4,000,000 could have been squandered. That the khedive is no financier is obvious; but he seems honestly determined to pay his debts, and if there was any dishonesty in the matter of the loans it was not on the khedive's side.

The principal exports from Egypt are cotton, cereals, and sugar. In 1876, 163,912,336 lb of raw cotton was exported to Great Britain, at the value of £6,668,340, and the total cotton export is estimated at over two millions and a half of quintals. Of beans, 490,257 ardebs were exported in 1875; of wheat, 836,997 ardebs, of sugar, 986,000 quintals. Maize, barley, flax, natron, dates, linseed, and other produce form less important items in the list of exports. The total value of exports is estimated at between twelve and thirteen million of pounds. The imports are estimated at about five millions and a half of pounds and consist chiefly of manufactured goods, coals, oil, wine, machinery, &c. Of the whole commerce about 70 per cent. is with Great Britain. There is also a considerable transit trade, which, however, has necessarily diminished since the opening of the Suez Canal.

The Egyptian measures are—the fitr, or space measured by the extension of the thumb and first finger; the shubr, or span; and the cubit (of three kinds, = 22½, 25, and 26½ inches). The measure of land is the feddân, very nearly equal to the English acre, subdivided into 24 keerâts, and each of these into 330 (formerly 333½) kasabebs, or rods, the kasabeb being a square measure with side of 22 kabdebs, each equaling 6½ inches. The ardobb is equal to about 5 bushels, and is divided into 6 weybebs, and each weybeb into 24 rubas.

The weights are these —

- 64 krmahs (or grains of wheat), or 48 habbebs (or grains of barley) = 1 dirhem (= 48 gr. Troy).
- 12 dirhems = 1 wukeeyeh or ounce (= about 575 gr.)
- 12 wukeeyehs = 1 ratl or pound (= 15 oz. 13 dr. avoirdupois)
- 27 ratls = 1 wukkah or oke (= 2½ lb.)
- 36 wukkahs = 1 kantâr or cwt. (= 99 lb.)
- 24 keerâts = 1 muthkâl or weight of a deenâr (= 72 gr.)

The French metrical system has been established by the khedive, but has not yet been generally adopted.

The standard unit of currency is the kirsh, or piastro (= about 2½d), which is coined in gold pieces of 5, 10, 20, 25, 50, 100 piastres: silver of 1, 2½, 5, 10, 20 piastres.

Copper coins of 5, 10, 20 paras (or faddahs, 40 to the piastre) and 1 piastre are also coined. The kees, or purse, of 500 piastres, is equal to about £5, 2s. 6d. The khazneh, or treasury, consists of 1000 purses. 97½ piastres are given for the English pound sterling. Besides the regular

Egyptian currency, European coins of all kinds are commonly employed in Egypt, especially the English sovereign, the French Napoleon, the Venetian sequin, the Spanish doubloon and dollar, the 5-franc picco, and the Constantinople coins. (S. L. P.) (R. S. P.)

Ehrenbreitstein, a small town in Prussia, in the circle of Coblenz, situated on the right bank of the Rhine, and connected with the town of Coblenz by a bridge of boats, is of importance as possessing a magnificent fortress erected upon a precipitous rock 401 feet above the Rhine. The castle which occupied the site of the modern building is said to have been presented in 636 by the Franconian king Dagobert to the archbishops of Treves. It was twice taken by the French—in 1631 and 1799, and at the peace of Lunéville in 1801 they blew it up before evacuating it. At the second Peace of Paris the French paid 15,000,000 francs to the Prussian Government for its restoration, and the works begun in 1816 were completed in ten years. The town possesses a few ships, and has a wine and carrying trade. In 1875 the population, including the garrison, was 4901. See **COBLENZ**.

Eibenstock, a town in Saxony, in the circle of Zwickau, is situated on the borders of Bohemia, 16 miles S.S.E. of Zwickau. It possesses chemical and tobacco manufactories, and tin and iron works. Lace-making was introduced in 1775 by Clara Angermann. It has also a large cattle market. Population in 1875, 6553.

Eichendorff, Joseph, Freiherr von (1788—1857), a German poet and romance-writer, was born at Lubowitz, near Ratibor, in Prussia. He studied law at Halle and Heidelberg from 1805 to 1808. After a visit to Paris he went to Vienna, where he resided until 1813, when he joined the Prussian army as a volunteer. When peace was concluded in 1815 he left the army, and in the following year he was appointed to a judicial office at Breslau. He subsequently held similar offices at Dantzic, Königsberg, and Berlin. Retiring from the public service in 1844, he afterwards resided successively in Dantzic, Vienna, Dresden, and Berlin. He died at Neisse on the 26th November 1857. Eichendorff was one of the most distinguished of the later members of the German romantic school. His genius was essentially lyrical, and he was deficient in the distinctive dramatic faculty. On this

account he is most successful in his shorter romances and dramas, where constructive power is least called for. His first work, a romance entitled *Ahnung und Gegenwart*, appeared in 1815. This was followed at short intervals by several others, among which the foremost place is by general consent assigned to *Aus dem Leben eines Taugenichts* (Berlin, 1824), which has often been reprinted. Of his dramas may be mentioned *Ezzelin von Romano*, a tragedy (1828), *Meierbells Glück und Ende*, a tragedy (1828); and *Die Freier*, a comedy (1833). He also translated Calderon's *Geistliche Schauspiele* (1846) from the Spanish. Eichendorff's lyric poems were of a very high order, and many of them were set to music by composers of eminence. In the later years of his life he published several valuable works on subjects in literary history and criticism, such as *Ueber die ethische und religiöse Bedeutung der neueren romantischen Poesie in Deutschland* (1847), *Der deutsche Roman des 18. Jahrhundert in seinem Verhältniss zum Christenthum* (1851), and *Geschichte der poetischen Literatur Deutschlands* (1856). An edition of his collected works in six volumes appeared at Leipzig in 1870.

Eichhorn, Johann Gottfried (1752—1827), an eminent scholar, historian, and writer on biblical criticism, was born at Dorrenzimmern, in the duchy of Hohenlohe-Oehringen, on the 16th October 1752. Here his father was minister, but shortly after the birth of Johann he was appointed superintendent of the state school in Weikersheim. At his father's school and at the gymnasium at Heilbronn young Eichhorn received his early education. In 1770 he entered the university of Göttingen, where he remained till 1774. In 1774 he received the rectorship of the gymnasium at Oehdriff, and in the following year was made professor of Oriental languages at Jena. On the death of Michaelis in 1788 he was elected ordinary professor of philosophy at Göttingen, where he lectured not only on the Oriental languages and on the exegesis of the Old and New Testaments, but also on general history. In 1811 he was made doctor of theology, in 1813 joint-director of the Royal

Scientific Society of Göttingen, and in 1819 Geheimer Justizrath of Hanover. His health was shattered by an attack of inflammation of the lungs in the year 1825, but he regularly continued his prelections to a large number of students until attacked by fever on the 14th June 1827. He died on the 27th of that month. Eichhorn is the author of a good many historical works, but it is as a biblical critic that he is best known. He may almost be said to have originated the science of biblical criticism, for he first properly recognized its scope and the problems it had to solve, and began many of its most important discussions. He was the first to see the necessity of finding a firm historical foundation for everything in Christianity that was to be accepted as fact. Preliminary to his endeavours towards this end, he took for granted that all the so-called supernatural facts relating to the Old and New Testaments were explicable on natural principles. He sought to judge them from the stand-point of the ancient world, and to account for them by the superstitious beliefs which were then generally in vogue. He did not perceive in the biblical books any religious ideas of much importance for modern times; they interested him merely historically, and for the light they cast upon antiquity. The supernatural element which they contained he attributed partly to the artificial delusions of magic, and partly to the natural delusions of a superstitious time. He regarded as ungemine many books of the Old Testament and some of the Epistles, and he was the first to suggest that the Gospels were compiled by later writers from documents which have now perished. He did not appreciate as sufficiently as Strauss and the Tübingen critics the difficulties which a natural theory has to surmount, nor did he support his conclusions by such elaborate and minute discussions as they have deemed necessary, but he may be justly denominated the founder of their school of biblical criticism.

His principal works were—*Geschichte des Ostindischen Handels vor Mohammed*, Götting, 1776; *Allgemeine Bibliothek der biblischen Literatur* (10 vols. Lpz. 1787–1801); *Einleitung in das Alte Testament* (5 vols. Gott. 1824); *Einleitung in das Neue Testament* (5 vols. Gott. 1821–27); *Einleitung in die apokryphischen Schriften des Alten Testaments* (Gott. 1798); *Commentarius in apocalypsin Joannis* (2 vols. Gott. 1791); *Die Hebr. Propheten* (3 vols. Gott. 1816–20); *Allgemeine Geschichte der Cultur und Literatur des neuen Europa* (2 vols. Gott. 1796–99); *Laterargeschichte* (1st vol. Gott. 1799, 2d ed. 1813, 2d vol. 1814); *Geschichte der Literatur von ihrem Anfange bis auf die neuesten Zeiten* (6 vols. Gott. 1805–12); *Uebersicht der Französischen Revolution* (2 vols. Gott. 1797); *Weltgeschichte* (3d ed. 5 vols. Gott. 1810–20); *Geschichte der drei letzten Jahrhunderte* (3d ed. 6 vols. Hanover, 1817–18); *Urgeschichte des erlaucheten Hauses der Welfen* (Hanover, 1817).

EICHHORN, KARL FRIEDRICH (1781–1854), a son of the preceding, and a learned writer on jurisprudence, was born at Jena on the 20th November 1781. He entered the university of Göttingen in 1797. In 1805 he obtained the professorship of law at Frankfurt-on-the-Oder, holding it till 1811, when he accepted the same chair at Berlin. On the call to arms in 1813 he became a captain of horse, and he received at the end of the war the decoration of the Iron Cross. In 1817 he was offered the chair of law at Göttingen, and, preferring it to the Berlin professorship, taught at Göttingen with great success till ill health compelled him to resign in 1828. His successor in the Berlin chair having died in 1832, he again entered on its duties, but resigned it two years afterwards. In 1832 he also received an appointment in the ministry of foreign affairs, which, with his labours on many state committees and his legal researches and writings, occupied him till his death in July 1854. Eichhorn is regarded as one of the principal authorities on German constitutional law. His chief work is *Deutsche Staats- und Rechtsgeschichte*, 4 vols. In company first with Savigny and Göschen, and then with Rudorf, he edited the *Zeitschrift für geschichtliche Rechtswissenschaft*.

He is the author besides of *Einleitung in das deutsche Privatrecht mit Einschluss des Lehnrechts* and the *Grundsätze des Kirchenrechts der kath. und evang. Religionspartei in Deutschland*.

EICHSTADT, or EICHSTATT, originally Eistet, a town in the Bavarian district of Franconia, is situated in a deep valley on the Altmühl, about 35 miles south of Nuremberg. It is inclosed by walls, and has a very antique appearance. It is the seat of a bishop, and since 1838 of the appeal court of Middle Franconia. The making of stoneware, iron smelting, brewing, and weaving constitute its chief industries. It possesses a good many educational institutions. Among its principal buildings are the palace occupied by the dukes of Leuchtenberg, with its beautiful park, and containing a celebrated Brazilian cabinet; the town-house; the cathedral, containing some beautiful paintings and windows, and the grave of Wihbald, the first bishop and founder of the town, and the church of St Walpurgis, under whose altar the bones of the saint of that name are said to rest. Near the town is the famous stronghold Wihbaldsburg, occupying the site of a Roman castle, and built for a bishop's residence by St Wihbald in 740.

Eichstadt was founded by St Wihbald in 745. The bones of St Walpurgis were brought to the town in 871, and from that time it became a great resort of pilgrims. Through the death of Count von Hirschberg in 1805, the bishopric became one of the richest foundations of Germany. It was secularized in 1802, became a principality of E. Bavaria in the same year, and still in the same year passed into the possession of Duke Ferdinand of Tuscany, who again transferred it to Bavaria in 1805. In 1817 it was assigned to the duke of Leuchtenberg. It lost its principality in 1854. The population in 1875 was 7136.

EIDER (Icelandic, *Ædur*), a large marine Duck, the *Somateria mollissima* of ornithologists, famous for its down, which, from its extreme lightness and elasticity, is in great request for filling bed-coverlets. This bird generally frequents low rocky islets near the coast, and in Iceland and Norway has long been afforded every encouragement and protection, a fine being inflicted for killing it during the breeding-season, or even for firing a gun near its haunts, while artificial nesting-places are in many localities contrived for its further accommodation. From the care thus taken of it in these countries it has become exceedingly tame at its chief resorts, which are strictly regarded as property, and the taking of eggs or down from them, except by authorized persons, is severely punished by law. In appearance the Eider is somewhat clumsy, though it flies fast and dives admirably. The female is of a dark reddish-brown colour barred with brownish-black. The adult male in spring is conspicuous by his pied plumage of sable beneath, and creamy-white above: a patch of shining sea-green on his head is only seen on close inspection. This plumage he is considered not to acquire until his third year, being when young almost exactly like the female, and it is certain that the birds which have not attained their full dress remain in flocks by themselves without going to the breeding-stations. The nest is generally in some convenient corner among large stones, hollowed in the soil, and furnished with a few bits of dry grass, seaweed, or heather. By the time that the full number of eggs (which rarely if ever exceeds five) is laid the down is added. Generally the eggs and down are taken at intervals of a few days by the owners of the "Eider-feld," and the birds are thus kept depositing both during the whole season; but some experience is needed to insure the greatest profit from each commodity. Every Duck is ultimately allowed to hatch an egg or two to keep up the stock, and the down of the last nest is gathered after the birds have left the spot. The story of the Drake's furnishing down, after the Duck's supply is exhausted, is a fiction. He never gets near the nest. The eggs have a strong flavour, but are much relished by

both Icelanders and Norwegians. In the Old World the Eider breeds in suitable localities from Spitsbergen to the Farn Islands off the coast of Northumberland—where it is known as St Cuthbert's Duck. Its food consists of marine animals (mollusks and crustaceans), and hence the young are not easily reared in captivity. The Eider of the New World differs somewhat from our own, and has been described as a distinct species (*S. dresseri*). Though much diminished in numbers by persecution, it is still abundant on the coast of Newfoundland and thence northward. In Greenland also, Eiders are very plentiful, and it is supposed that three-fourths of the supply of down sent to Copenhagen comes from that country. The limits of the Eider's northern range are not known, but the late Arctic Expedition does not seem to have met with it after leaving the Danish settlements, and its place is taken by an allied species, the King-Duck (*S. spectabilis*), a very beautiful bird which sometimes appears on the British coast. The female greatly resembles that of the Eider, but the male has a black chevron on his chin and a bright orange prominence on his forehead, which last seems to have given the species its English name. On the west coast of North America the Eider is represented by a species (*S. v-nigrum*) with a like chevron, but otherwise resembling the Atlantic bird. In the same waters two other fine species are also found (*S. fischeri* and *S. stelleri*), one of which (the latter) also inhabits the Arctic coast of Russia and East Finnmark and has twice reached England. The Labrador Duck (*S. labradoria*), which is now believed to be extinct (see BIRDS, vol. iii. p. 735), also belongs to this group. (A. N.)

EILENBURG, a town of Prussia, in the province of Saxony, government of Merseburg, and circle of Delitzsch, is situated on an island formed by the Mulde, about 18½ miles north-east of Leipzig. The principal structures are the hospital, the infirmary, three churches, and the castle. From the last-mentioned, formerly known as Ilburg, and in the time of Henry the Fowler an important post of defence against the Sorbs and Wends, the town received its name. The industries include the manufacture of chemicals, cloth, quilting, calico, cigars, and agricultural implements, bleaching, dyeing, wax-refining, brick-making, and trade in cattle. In the neighbourhood is the iron-foundry of Erwinhof. The population was 10,312 in 1875.

EINBECK, or **EMBECK**, a town of Prussia, in the landrost of Hildesheim, and province of Hanover, formerly chief town of the principality of Grubenhagen, is situated on the Ilme, 39 miles south of Hanover. It possesses a cathedral, five churches, a Jewish synagogue, a progymnasium and other schools, and several endowed institutions. Among the manufactures are linen and woollen goods, spun stockings, carpets, sugar, leather, cigars, chemicals, and beer, for which last the place was once famous. Population in 1875, 6384.

Einbeck owes its rise to the frequent pilgrimages made in early times to the "Blood of the Saviour" at the cathedral chapel. It was a fortified Hanse town, and in 1642 joined the Smalcaldic League. On March 24, 1626, it was taken by Pappenheim, and on October 14, 1641, by Piccolomini, and during the Seven Years' War it was repeatedly occupied by the French.

EINSIEDELN, a town in the canton of Schwyz, in Switzerland, situated in the valley of the Sihl, eight miles N.N.E. of Schwyz. The Benedictine abbey of Einsiedeln, founded about the middle of the 9th century, was several times partially or wholly destroyed by fire. The present edifice, in the Italian style, was erected in 1704–19, and stands at an elevation of 2985 feet above sea-level. It contains a library of 40,000 volumes, 1190 manuscripts, and 1015 incunabula, and in connection with it are a priests' seminary, a gymnasium, and a lyceum. The emperors Otto the Great and Henry II. made valuable presents to the abbey, and in 1274 Rudolf of Hapsburg

created the abbot a prince. The treasury was plundered by the French in 1798. The abbey has for centuries been noted for its sacred image of the Virgin, which brings to it yearly an average of 150,000 pilgrims, chiefly on the 14th of September. Most of the buildings of Einsiedeln are inns for the entertainment of the pilgrims, with whom the inhabitants traffic in missals, sacred pictures, rosaries, crucifixes, and medallions. The Reformer Zwingli preached at Einsiedeln in 1516–18, and not far from the town is the house where Paracelsus is said to have been born. Population about 7650.

EISENACH, the chief town of the Eisenach circle and of the administrative department of Saxe-Weimar-Eisenach, lies in a romantic district at the north-west end of the Thuringian wood. It is situated on the Horsa, at the junction of the Thuringian and Werra railways, and 44 miles west from Weimar. In its neighbourhood is the Wartburg, where Luther on his return from the Diet of Worms was imprisoned, and where from May 1521 to March 1522 he devoted himself to the translation of the Bible. On a high rock on the south side of the town are the ruins of the castle of Mädelstein. Eisenach is the birth-place of Sebastian Bach, and he and Luther were educated at its gymnasium, then the Latin school. Among the public buildings may be mentioned the tower of St Nicholas, the castle, rebuilt in 1742, and the town-house, erected in 1641. Eisenach has a manufactory for cotton cloth, and a large woollen and several other mills. Population in 1875, 16,163.

EISENBERG, a town in the west circle of the duchy of Saxe-Altenburg, and 24 miles W.S.W. of Altenburg. It is very old, and has changed possessors more than once, but was joined to Saxe-Altenburg in 1826. It possesses an old castle and a beautiful church. Its industries are principally woollen and porcelain manufactures, linen-weaving, and shoe-making. Population in 1875, 5509.

EISENBURG, or **VAS VÁRMEGYE**, a county of Western Hungary, on the Styrian frontier, inclosed on the north, east, and south by the counties of Sopron, Veszprim, and Szala, and on the west by the Styrian circle of Gratz. Its area is 1536 geogr. square miles. Though mountainous in the west and south, the land is generally fertile. The chief river is the Raab, which receives the Pinka, Sorok, Gyongyos, and other streams. The natural and agricultural products consist of coals, mineral waters, quicksilver, corn, wine, fruit, and tobacco. Game, wild fowl, and fish are also plentiful. The population in 1870 amounted to 331,602, of whom nearly three-fourths were Roman Catholics, the rest chiefly Protestants and Jews. According to nationality about 140,000 are Magyars, 120,000 Germans, and the remainder Croats and Slovaks. The principal town is Szombathely or Stein-am-Anger.

EISENSTADT, or **KIS-MARTON**, a royal free town of East Hungary, in the vármegye or county of Sopron or Oedenburg, in 47° 51' N. lat and 16° 30' E. long., is situated at the foot of the Leitha mountain range, not far from the west bank of Lake Neusiedl, 26 miles S.E. of Vienna. The town is famous as being the seat of Prince Esztorházy, whose castle of Kis-Martón is one of the finest palaces in Hungary. It was built by Prince Paul, palatine of Hungary, in 1683, but was improved and added to in 1805. The park, which is very large, has a fine orangery, and several conservatories, containing many thousand varieties of exotic plants. The town itself is walled round, and has three main streets, with an old church, a town-hall, hospitals, and monasteries of the Brothers of Charity and of the Franciscans. To the north of the town there are extensive zoological gardens. The population in 1870 amounted to 2476.

EISLEBEN (Latin, *Islebia*), the chief town of the Mansfield circle, in the government of Merseburg, province of Saxony, Prussia, is situated on the railway from Hallo to Nordhausen and Cassel, 18 miles west from Halle. It consists of an old and a new town, the former being surrounded by walls. In the vicinity are extensive copper and silver mines, and the town itself possesses smelting furnaces, several breweries, and manufactories of linen, tobacco, and saltpetre. Among its principal buildings are—the old castle; the church of St Andrews, which contains numerous monuments of the counts of Mansfield; the church of St Paul and St Peter, in which is the font where Luther was baptized; the Royal Gymnasium, founded by Luther shortly before his death in 1546; and the hospital. Eisleben is celebrated as the place where Luther was born and died. The house in which he was born was burned in 1689, but was rebuilt in 1693 as a free school for orphans, that in which he died has lately been renovated, and his death-chamber is still preserved.

The first mention of Eisleben dates from the 11th century. During the insurrection of the peasants in 1525, it was partly destroyed, and it was immediately after this that the new town was founded. In 1780, when the counthip of Mansfield became extinct, Eisleben came into the possession of Saxony, and in 1815 of Prussia. The population in 1875 was 14,378.

EISTEDDFOD, Yr (plural *Eisteddfodau*), the national bardic congress of Wales, the objects of which are to encourage bardism and music and the general literature of the Welsh, to maintain the Welsh language and customs of the country, and to foster and cultivate a patriotic spirit amongst the people. This institution, so peculiar to Wales, is of very ancient origin.¹ The term *Eisteddfod*, however, which means "a session" or "sitting," was probably not applied to bardic congresses before the 12th century.

The Eisteddfod in its present character appears to have originated in the time of Owain ap Maxon Wledig, who at the close of the 4th century was elected to the chief sovereignty of the Britons on the departure of the Romans. It was at this time, or soon afterwards, that the laws and usages of the Gorsedd were codified and remodelled, and its motto of "Y gwir yn erbyn y byd" (The truth against the world) given to it. "Chairs" (with which the Eisteddfod as a national institution is now inseparably connected) were also established, or rather perhaps resuscitated about the same time. The chair was a kind of convention where disciples were trained, and bardic matters discussed preparatory to the great Gorsedd, each chair having a distinctive motto. There are now existing four chairs in Wales, —namely, the "royal" chair of Powys, whose motto is "A laddo a leddir" (He that slayeth shall be slain); that of Gwent and Glamorgan, whose motto is "Duw a phob daioni" (God and all goodness); that of Dyfed, whose motto is "Calon wrth galon" (Heart with heart); and that of Gwynedd, or North Wales, whose motto is "Iesu," or "O Iesu! na'd gamwaith" (Jesus, or Oh Jesus! suffer not iniquity).

The first Eisteddfod of which any account seems to have descended to us was one held on the banks of the Conway in the 6th century, under the auspices of Maelgwn Gwynedd, prince of North Wales. Maelgwn on this occasion, in order to prove the superiority of vocal song over instrumental music, is recorded to have offered a reward to such bards and minstrels as should swim over the Conway. There were several competitors, but on their arrival on

the opposite shore, the harpers found themselves unable to play, owing to the injury their harps had sustained from the water, while the bards were in as good tune as ever King Cadwaladr also presided at an Eisteddfod about the middle of the 7th century.

Griffith ap Cynan, prince of North Wales, who had been born in Ireland, brought with him from that country many Irish musicians, who greatly improved the music of Wales. During his long reign of 56 years he offered great encouragement to bards, harpers, and minstrels, and framed a code of laws for their better regulation. He held an Eisteddfod about the beginning of the 12th century at Caerwys in Flintshire, "to which there repaired all the musicians of Wales, and some also from England and Scotland." For many years afterwards the Eisteddfod appears to have been held triennially, and to have enforced the rigid observance of the enactments of Griffith ap Cynan. The places at which it was generally held were Aberffraw, formerly the royal seat of the princes of North Wales, Dynevor, the royal castle of the princes of South Wales, and Mathrafal, the royal palace of the princes of Powys, and in later times Caerwys in Flintshire received that honourable distinction, it having been the princely residence of Llewelyn the Last. Some of these Eisteddfodau were conducted in a style of great magnificence, under the patronage of the native princes. At Christmas 1107, Cadwgan, the son of Bleddyn ap Cynfyn, prince of Powys, held an Eisteddfod in Cardigan Castle, to which he invited the bards, harpers, and minstrels, "the best to be found in all Wales," and "he gave them chairs and subjects of emulation according to the custom of the feasts of King Arthur." In 1176 Rhys ab Gruffydd, prince of South Wales, held an Eisteddfod in the same castle on a scale of still greater magnificence, it having been proclaimed, we are told, a year before it took place, "over Wales, England, Scotland, Ireland, and many other countries."

On the annexation of Wales to England, Edward I deemed it politic to sanction the bardic Eisteddfod by his famous statute of Rhuddlan. In the reign of Edward III. Ifor Hael, a South Wales chieftain, held one at his mansion. Another was held in 1451, with the permission of the king, by Griffith ab Nicholas at Carmarthen, in princely style, where Dafydd ab Edmund, an eminent poet, signalized himself by his wonderful powers of versification in the Welsh metres, and whence "he carried home on his shoulders the silver chair" which he had fairly won. Several Eisteddfodau were held, one at least by royal mandate, in the reign of Henry VII. In 1523 one was held at Caerwys before the chamberlain of North Wales and others, by virtue of a commission issued by Henry VIII. In the course of time, through relaxation of bardic discipline, the profession was assumed by unqualified persons, to the great detriment of the regular bards. Accordingly in 1567 Queen Elizabeth issued a commission for holding an Eisteddfod at Caerwys in the following year, which was duly held, when degrees were conferred on 55 candidates, including 20 harpers. From the terms of the royal proclamation we find that it was then customary to bestow "a silver harp" on the chief of the faculty of musicians, as it had been usual to reward the chief bard with "a silver chair." This was the last Eisteddfod appointed by royal commission, but several others of some importance were held during the 16th and 17th centuries, under the patronage of the earl of Pembroke, Sir Richard Neville, and other influential persons. Amongst these the last of any particular note was one held in Bewper Castle, Glamorgan, by Sir Richard Basset in 1681.

During the succeeding 130 years Welsh nationality was at its lowest ebb, and no general Eisteddfod on a large scale appears to have been held until 1819, though several

¹ According to the Welsh Trads and other historical records, the Gorsedd or assembly (an essential part of the modern Eisteddfod, from which indeed the latter sprung) is as old at least as the time of Prydain the son of Aedd the Great, who lived many centuries before the Christian era. Upon the destruction of the political ascendancy of the Druids, the Gorsedd lost its political importance, though it seems to have long afterwards retained its institutional character as the medium for preserving the laws, doctrines, and traditions of bardism.

small ones were held under the auspices of the Gwyneddigion Society, established in 1771,—the most important being those at Corwen (1789), St Asaph (1790), and Caerwys (1798).

At the close of the Napoleonic wars, however, there was a general revival of Welsh nationality, and numerous Welsh literary societies were established throughout Wales, and in the principal English towns. A large Eisteddfod was held under distinguished patronage at Carmarthen in 1819, and from that time to the present they have been held, almost without intermission, annually, several of them being under royal patronage. The following is a list of the principal Eisteddfodau since that date—

1820, Wrexham, 1821, Carnarvon, 1822, Brecon; 1823, Carmarthen; 1824, Welshpool, 1826, Brecon, 1828, Denbigh, 1832, Beaumaris, 1834, Cardiff, 1835, Llanerchymedd; 1836, Liverpool, 1838, Merthyr, 1839, Liverpool, 1840, Abergavenny, 1842, Swansea, 1845, Abergavenny; 1849, Aberffraw; 1850, Rhuddlan, 1851, Tremadoc; 1853, Liverpool and Portmadoc; 1854, Festiniog, 1855, Dinas Mawddwy, Machraeth, and Morriston; 1858, Llangollen (memorable for its archaic character, and the attempts then made to revive the ancient ceremonies and restore the ancient vestments of druids, bards, and orates), 1859, Merthyr, 1860, Denbigh, 1861, Conway and Aberdare; 1862, Carnarvon, 1863, Swansea and Rhyl, 1864, Llandudno; 1865, Aberystwith, 1866, Chester, 1867, Carmarthen; 1868, Ruthin, 1869, Llanerchymedd, 1870, Rhyl, 1871, Towyn, 1872, Portmadoc; 1873, Mold; 1874, Bangor, 1875, Pwllheli; 1876, Wrexham; and 1877, Carnarvon.

Besides these, innumerable local Eisteddfodau have been held during the last 50 years.

To constitute a provincial Eisteddfod it is necessary that it should be proclaimed by a graduated bard of a Gorsedd a year and a day before it takes place. A local one may be held without such a proclamation. A provincial Eisteddfod generally lasts three, sometimes four days, during which thousands of persons of all classes and from all parts of Wales and many English towns attend. Many of these being unacquainted with the Welsh language, a large portion of the public proceedings are conducted in English. A president and a conductor are appointed for each day. The proceedings commence with a Gorsedd meeting, opened with sound of trumpet and other ceremonies, at which candidates come forward and receive bardic degrees after satisfying the presiding bard as to their fitness. At the subsequent meetings the president gives a brief address; the bards follow with poetical addresses; adjudications are made, and prizes and medals with suitable devices are given to the successful competitors for poetical, musical, and prose compositions, for the best choral and solo singing, and singing with the harp or "Pennillion singing" as it is called, for the best playing on the harp or stringed or wind instruments, as well as occasionally for the best specimens of handicraft and art. In the evening of each day a concert is given, generally attended by very large numbers. The great day of the Eisteddfod is the "chair" day—usually the third or last day—the grand event of the Eisteddfod being the adjudication on the chair subject and the chairing and investiture of the fortunate winner. This is the highest object of a Welsh bard's ambition. The ceremony is an imposing one, and is performed with sound of trumpet. See CELTIC LITERATURE, vol. v. pp. 318, 319, and for authorities, p. 327.

(R. W.)*

* According to Jones's *Bardic Remains*, "To sing 'Pennillion' with a Welsh harp is not so easily accomplished as may be imagined. The singer is obliged to follow the harper, who may change the tune, or perform variations *ad libitum*, whilst the vocalist must keep time, and end precisely with the strain. The singer does not commence with the harper, but takes the strain up at the second, third, or fourth bar, as best suits the 'pennill' he intends to sing."

Those are considered the best singers who can adapt stanzas of various metres to one melody, and who are acquainted with the twenty-four measures according to the bardic laws and rules of composition."

EJECTMENT, in English law, was an action for the recovery of the possession of land, together with damages for the wrongful withholding thereof. In the old classification of actions, as real or personal, this was known as a mixed action, because its object was twofold, viz., to recover both the realty and personal damages. The form of the action as it prevailed in the English courts down to the Common Law Procedure Act, 1852, was a series of fictions, among the most remarkable to be found in the entire body of English law. The following outline is condensed from the work of Mr Sergeant Adams:—A, the person claiming title to land, delivers to B, the person in possession, a declaration in ejectment, in which C and D, fictitious persons, are plaintiff and defendant. C states that A has devised the land to him for a term of years, and that he has been ousted by D. A notice signed by D informs B of the proceedings, and advises him to apply to be made defendant in D's place, as he, D, having no title, does not intend to defend the suit. If B does not so apply, judgment will be given against D, and possession of lands will be given to A. But if B does apply, the court allows him to defend the action only on condition that he admits the three fictitious averments—the lease, the entry, and the ouster—which, together with title, are the four things necessary to maintain an action of ejectment. This having been arranged, the action proceeds, B being made defendant instead of D. The names used for the fictitious parties were John Doe, plaintiff, and Richard Roe, defendant, who was called the casual ejector. The explanation of these mysterious fictions is this. The writ of *ejectione firmæ* was invented about the beginning of the reign of Edward III. as a remedy to a lessee who for years had been ousted of his term. It was a writ of trespass, and carried damages, but in course of time the courts of common law added thereto "a species of remedy neither warranted by the original writ nor demanded by the declaration, viz., a judgment to recover the term and a writ of possession thereupon." The next step was to extend the remedy to cases of disputed title to freeholds. This was done indirectly by the claimant entering on the land and there making a lease for a term of years to another person; for it was only a term that could be recovered by the action, and to create a term required actual possession in the grantor. The lessee remained on the land, and the next person who entered even by chance was accounted an ejector of the lessee, who then served upon him a writ of trespass and ejectment. The case then went to trial as on a common action of trespass; and the claimant's title, being the real foundation of the lessee's right, was thus indirectly determined. These proceedings might take place without the knowledge of the person really in possession; and to prevent the abuse of the action a rule was laid down that the plaintiff in ejectment must give notice to the party in possession, who might then come in and defend the action. When the action came into general use as a mode of trying the title to freeholds, the actual entry, lease, and ouster which were necessary to found the action were attended with much inconvenience, and accordingly Lord Chief-Justice Rolle during the Protectorate substituted for them the fictitious averments already described. The action of ejectment is now only a curiosity of legal history. Its fictitious suitors were swept away by the Common Law Procedure Act of 1852. A form of writ was prescribed, in which the person in possession of the disputed premises by name and all persons entitled to defend the possession were informed that the plaintiff claimed to be entitled to possession, and required to appear in court to defend the possession of the property or such part of it as they should think fit. In the form of the writ and in some other respects ejectment still differed from other actions. But now by the Judicature

Act, 1875, all actions are begun and carried on in the same manner, and an action for the recovery of land will, with very few exceptions, proceed in the same manner as any other action.

EKATERINBURG, or **YEKATERINBURG**, a town of Asiatic Russia, at the head of a department in the province of Perm, on the Siberian highway, about 238 miles to the south-east of Perm, in $56^{\circ} 49' N.$ lat. and $60^{\circ} 35' E.$ long. It is situated near the eastern skirt of the Ural Mountains, and occupies both banks of the Isset, which is there crossed by a dam and forms a valuable reservoir for industrial purposes. In 1834 it was made the seat of a suffragan bishop, and it has long been the head-quarters of the administration of the mines, not only for the immediate neighbourhood, but also for the Bogosloff, Goroblagodat, Perm, Zlatoustoff, and Kam-Votkin districts. The streets are broad and regular, and several of the houses of palatial proportions. There are two cathedrals—St Catherine's founded in 1758, and Epiphany in 1774, with more than a dozen churches and a monastery, two gymnasiums, a departmental school, a city infirmary, a workmen's hospital, an almshouse, a children's home, a prison, a theatre, and a museum opened in 1853. Besides the Government mint for copper coinage, which dates from 1735, the Government engineering works, and the imperial factory for the polishing of malachite, jasper, marble, porphyry, and other ornamental stones, the industrial establishments comprise tallow-factories, soap-works, glue-works, rope-works, distilleries, potteries, and carriage factories. The trade is very extensive, especially in cattle, grain, iron, woollen and silk stuffs, and colonial wares; and besides a weekly market there are two annual fairs. The population in 1860 numbered 19,832, mostly belonging to the Greek Church, only 47 being Catholics, 198 Protestants, and 36 Mahometans; in 1871 it had increased to 25,233.

Ekaterinburg took its origin from the mining establishments founded on the spot by Peter I. in 1723, and received its name in honour of Catharine I. Its development was greatly promoted in 1763 by the Siberian highway, which till then had passed by Verkhoturic, being diverted so as to pass through it; and the gradual extension of mining operations in the district has maintained its prosperity. In 1781 the town was transferred from the Tobolsk department to the government of Perm, and in 1863 passed from the jurisdiction of the Administration of Mines to the ordinary civil jurisdiction.

EKATERINODAR, the chief town of the Russian government of Kuban, on the right bank of the Kuban, near the confluence of the Karasuk, in $45^{\circ} 3' N.$ lat. and $38^{\circ} 30' E.$ long, 1400 miles from St Petersburg and 555 north west of Tiflis. It is badly built on a swampy site exposed to the inundations of the river; and its houses, with few exceptions, are slight structures of wood and plaster. Six churches, a gymnasium, two schools, and a hospital are the principal public buildings. None of the industrial establishments, which comprise soap-works, tanneries, brick-works, and potteries, are of more than local importance; but there is a fair trade in horses, cattle, sheep, wool, and fish. In the neighbourhood is a large garden and orchard maintained by the Government for the encouragement of horticulture. The town dates from the reign of Catharine II., when in 1792 the Zaporogian Cossacks were transferred to the Kuban district. In 1860 the population amounted to 9620, mainly Cossacks; in 1871 it was 17,622.

EKATERINOSLAF, or **EKATERINOSLAVSKAYA GUBERNIE**, a government of Southern Russia, which lies partly to the W. of the Dnieper, stretches E. to the Donetz and the Kalmius, and in the S reaches the Sea of Azoff between the mouths of the Berda and the Kalmius. It is watered by the Dnieper for 220 miles, and bounded by the Donetz for 132. The district of Rosstoffs, lying round the head of

the Gulf of Taganrog, though naturally a portion of the Country of the Don, is also assigned to Ekaterinoslaff. According to the military survey, the area of the government is 26,095 square miles, or 59,185 square versts; according to Schweizer, only 25,644 square miles, or 58,338 square versts. Its surface is a steppe-like plain, relieved here and there by considerable elevations, and traversed by deep ravines and river courses. The most important range of hills, or those forming the water-shed between the tributaries of the Donetz and the independent affluents of the Sea of Azoff, attains no greater height than 530 feet above sea-level. A line drawn from near the mouth of the Orel parallel with the Dnieper as far as the town of Ekaterinoslaff, and thence to the village of Karakub on the Kalmius, divides the government into two geological districts, of which the south-western is distinguished by crystalline and the north-eastern by sedimentary rocks. Of the former the predominant variety is gneiss, interrupted by numerous upheavals of granite, syenite, diorite, and serpentine. The latter belong to several different formations. Carboniferous strata occupy the greater part of the districts of Slavianskerbsk and Bakhmut and part of Pavlogradsk and Alexandrofsk; Permian strata occur within a very limited area in Bakhmutsk, Cretaceous strata form a narrow strip along the northern boundary of the government from Bakhmutsk to the confluence of the Orelka and the Orel; and Tertiary strata extend through nearly all the district of Novomoskoff and the southern part of Pavlogradsk. The mineral deposits of the government are of great value. Anthracite and coal are distributed along the northern Donetz, the Lugan, the Muschuk, the Kalmius, and various other streams. The quantity of coal obtained in 1861 exceeded 1,200,100 puds. Iron ore is present in the same districts, and is successfully worked in several places, as at the Government establishments on the Lugan. Excellent whetstone is procured in the Slavianskerbsk district, and transported throughout Russia. Asbestos, millstones, gypsum, marl, and rock salt, as well as building materials, are among the minor products. There are altogether about 200 lakes in the government, the largest, which is called the Solnei Liman or Salt Lagoon, though the water is fresh, has an area of nearly three square miles, and next in size is the Tememitz lake near Rosstoffs. The soil is for the most part very fertile, and agriculture is the principal occupation. Wheat is the staple cereal, and forms an important article of export; but rye, barley, and millet are cultivated for local consumption and distillation. Since about 1850 the culture of flax has attained considerable importance; wild rape-seed is also exported, and in small quantities hemp and the sunflower are grown. The sloe thorn is very abundant, and the fruit is manufactured into a wine called Terevka. The German colonists of Khorlitz and Alexandrovka and the Greeks of Mariupol cultivate tobacco—the former principally a poor American variety for local consumption, the latter Turkish for export. Potatoes are grown only in gardens, as to plant them in the fields is regarded as prejudicial. Horticulture is poorly developed, but there are beautiful public gardens at Taganrog and Ekaterinoslaff, the Petrofski park in the former city being also the oldest in the government. About 7,209,000 acres, or 45 per cent. of the territory of the government, is devoted to pasturage; and in 1861 there were 2,670,000 sheep, 730,000 neat, 200,000 horses. Only about two per cent of the surface is occupied by wood, and even that is almost exclusively confined to the river courses, especially of the Samara and the Dnieper. The trees are almost exclusively deciduous, oak predominating, and elm, larch, black poplar, poplar, and aspen occurring.

In 1860 the total population was 1,138,740, and in 1867, 1,281,482. At the former date there were about 35,000 Greeks, more than 23,000 Jews, more than 20,000 Germans, 10,000 Armenians, 9000 Moldavians and Wallachians, 7000 Poles, 7000 Lithuanians, 500 Servians, and 5000 Gipsies; while the Little Russians and the Great Russians stood to each other in the ratio of 83 to 17. Upwards of 5500 were Russian dissenters or Raskolniki, 20,318 Protestants, and 7040 Catholics. Two cities only, Rostoff and Taganrog had more than 20,000 inhabitants; four, Ekaterinoslaff, Nakhichevan, Bakmut, and Petrokovka, had upwards of 10,000; and several, such as Novomoskoffsk, Pavlograd, Mariupol, and Azoff had more than 5000.

EKATERINOSLAFF, a town of European Russia, capital of the above government, is situated on the right bank of the Dnieper, at a height of 210 feet above the sea, 984 miles from St Petersburg and 600 from Moscow, in 48° 21' N. lat. and 34° 4' E long. If the suburb of Novi Koindak be included, it extends for upwards of four miles along the river, and its average breadth is about 1½ miles. The oldest part lies very low, and is consequently much exposed to floods. Contiguous to the town on the north-west is the royal village of Novi Maidaui or the New Factories, and in the south-east Kazannaya Mandrikovka. Only about 200 houses are built of stone. The bishop's palace, eight churches, a Raskolnik place of worship, a synagogue and four Jewish oratories, a gymnasium, a library, and several benevolent institutions, make up the list of the public buildings. The house now occupied by the Nobles' Club was formerly occupied by Potemkin. Among the industrial establishments are brickworks, foundries, flour-mills, and numerous tallow-boileries and soap-works. The general trade is rather restricted by the position of the town above the rapids of the Dnieper; but there is a very extensive trade in wood. Three yearly markets are held, at the largest of which the movement amounts to upwards of 2,200,000 roubles. Population in 1861, 18,881, of whom 3472 were Jews; in 1871, 24,267.

On the site of the town of Ekaterinoslaff there formerly stood the Polish castle of Koindak, built in 1635 by the French general Beauplan. The Cossacks, having destroyed the castle, founded the villages of Old and New Koindak and Polvitz. In 1786, the town was established by Potemkin, and in the following year the empress, Catherine II., with her own hand laid the foundation stone of the Cathedral of the Transfiguration. The schemes of Potemkin for the extension of the city were neglected after his death, and Paul I changed the very name into Novo Rossiesk. The original name was restored in 1802, and the city raised to its present rank. In 1830, the cathedral was built on the site originally proposed, but according to a less extensive scale.

EKHMEN, or AKHMEN, a town of Upper Egypt, a short distance from the right bank of the Nile, between two and three miles above Suhag. It is a place of about 3000 or 4000 inhabitants, has several mosques and two Coptic churches, maintains a weekly market, and manufactures shawls and checked cotton. Outside of the walls are the ruins of two ancient temples, one of which, identified by an inscription of the 12th year of the emperor Trajan as that of Pan, was regarded by Abulfeda as among the most important in Egypt.

Ekhmen, in Coptic Khmin or Shmig, is the ancient Chemmis or Panopolis, chief town of the Chemmite nome in the Thebaid, and, according to Strabo, inhabited by skilful stone-cutters and linen-weavers. It was reputed one of the oldest cities in the country. Herodotus particularly mentions a temple of Persens, and asserts that the inhabitants celebrated gymnastic games in honour of this hero; but it has not been ascertained to which of the Egyptian gods this account should be assigned. Panopolis probably decayed with the rise of Thebes, and long after it suffered greatly at the hands of the Arab invaders. At the time of Pococke's visit in 1738, it was still the seat of a powerful emir, who extended his protection to the Coptic Catholics; but the dynasty is long ago extinct, leaving nothing but its traditions and sepulchres behind. Nonnus, the Greek poet, was born at Chemmis in 410, and Nestorius died and was buried there about 447.

EKRON, in the Septuagint and Apocrypha Accaron (Ἀκαρών), a royal city of the Philistines, identified with

the modern Syrian village of Akir, five miles from Ramleh, on the southern slope of a low ridge separating the plain of Philistia from Sharon. Though included by the Israelites within the limits of the tribe of Judah, and mentioned in Judges xix. as one of the cities of Dan, it was in Philistine possession in the days of Samuel, and apparently maintained its independence. According to the narrative of the Hebrew text, here differing from the Septuagint and Josephus, it was the last town to which the ark was transferred before its restoration to the Israelites. Its maintenance of a sanctuary to Beelzebub is mentioned in 2 Kings i. At the time of the Crusades it was still a large village; but now, according to Porter, it contains only 50 mud houses, and has no visible remains of antiquity except two finely built walls.

ELAGABALUS. See Heliogabalus.

ELAM. This is the name given in Scripture to the province of Persia called Susiana by the classical geographers, from Susa or Shushan its capital. In one passage, however (Ezra iv. 9), it is confined to Elymais, the north-western part of the province, and its inhabitants distinguished from those of Shushan, which elsewhere (Dan. viii. 2) is placed in Elam. Strabo (xv. 3, 12, &c.) makes Susiana a part of Persia proper, but a comparison of his account with those of Ptolemy (vi. 3, 1, &c.) and other writers would limit it to the mountainous district to the east of Babylonia, lying between the Oroatis and the Tigris, and stretching from India to the Persian Gulf. Along with this mountainous district went a fertile low tract of country on the western side, which also included the marshes at the mouths of the Euphrates and Tigris and the north-eastern coast land of the Gulf. This low tract, though producing large quantities of grain, was intensely hot in summer; the high regions, however, were cool and well watered. The whole country was occupied by a variety of tribes, all speaking agglutinative dialects allied to each other and to the so-called Accadian language of primitive Chaldaea, but in very different stages of civilization. The most important of the tribes were the natives of southern Susiana, called Anzan in the cuneiform inscriptions, who established their capital at Susa, and founded a powerful monarchy there at a very early date. Strabo (xi. 13, 3, 6), quoting from Nearchus, seems to include them under the Elymaei, whom he associates with the Uxii, and places on the frontiers of Persia and Susa; but Pliny more correctly makes the Eulaeus the boundary between Susiana and Elymais (N. H., vi. 29-31). The Uxii are described as a robber tribe in the mountains adjacent to Media, and their name is apparently to be identified with the title given to the whole of Susiana in the Persian cuneiform inscriptions, *Uwaja*, or "Aborigines." *Uwaja* is probably the origin of the modern Khuzistan, though Mordtmann would derive the latter from *خوز* "a sugar-reed." Immediately bordering on the Persians were the Anardians or Mardians, in whom we may see the Apharsatheites and Apharsites of Ezra iv. 9, as well as Khapirti or Khalpriti, the name given to Susiana in the Protomedic cuneiform texts, which are written in the agglutinative dialect of the Turanian Medes and northern Elamites. Khapirti appears as Aipir in the inscriptions of Mal-Amir. Passing over the Messabatæ, who inhabited a valley which may perhaps be the modern Mäh-Sabadan, as well as the level district of Yamutbal or Yatbur (with its capital Duran or Deri) which separated Elam from Babylonia, and the smaller districts of Characene, Cabandene, Corbiana, and Gabieno mentioned by classical authors, we come to the fourth principal tribe of Susiana, the Cassi (Æsch., *Pers.*, 16; Strab. xv. 3, 2) or Cossæi (Strab. xi. 5, 6; xvi. 11, 17; Arr., *Ind.*, 40; Polyb. v. 54, &c.), the Cassi of the cuneiform inscriptions. So

important were they, that the whole of Susiana was sometimes called Cissia after them as by Herodotus (iii. 91; v. 49, &c.). In fact, Susiana was only a late name for the country, dating from the time when Susa had been made a capital of the Persian empire. The Accadians called it Numma, "the highlands" (compare the Vogl *numan*, "high"), or 'Subarti, with the same meaning, and of this the Semitic *Elamu* (from עלמה) was only a translation. Such was also the signification of the native Khapir or Aipir, also written Khubur, which is made synonymous with 'Subarti (comp. Eber, Gen. xi. 14). The Assyrian inscriptions have disposed of the suggestion, first made by J. Muller and Lassen, that Elam is a corrupt form of the Indo-European Airyama.

The principal mountains of Elam were on the north, called Charbannus and Cambalidus by Pliny (vi. 27, 31), and belonging to the Parachoathras chain. In the inscriptions they have the general name of "mountains of the east," which extended into Media, where "the mountain of Nizir," or "the mountain of the world," the present mount Elwend, was believed to be the spot on which the ark had rested, and the cradle of mankind. There were numerous rivers flowing into either the Tigris or the Persian Gulf. The most important were the Ulai or Eulæus (*Kūran*) with its tributary the Pasitigris, the Choaspes (*Kerkhah*), the Coprates (river of *Dis* called *Itito* in the inscriptions, the Hedyphon or Hedypnus (*Jerrāhi*), and the Oroatis (*Hindyan*), besides the monumental Surappi and Ukeni, or "white river," perhaps to be identified with the Hedyphon and Oroatis, which fell into the sea in the neighbourhood of the Caldai of Bit-Yagina, of Khindar, and of the Gambulai, in the marshy region at the mouth of the Tigris. Shushan or Susa, the capital, now marked by the mounds of *Shush*, stood near the junction of the Choaspes and Eulæus (see *SUSA*); and Badaca, Madaktu in the inscriptions, lay between the *Shapur* and the river of *Dis*. Among the other chief cities mentioned in the inscriptions, may be named Naditn, Khaltemas, Din-sar, Iubiln, Bit-imbi, Khidaln, and Nagitu on the sea coast. Here, in fact, lay some of the oldest and wealthiest towns, the sites of which have, however, been removed inland by the silting up of the shore. The monumental Dilvan, for instance, which according to Sargon was an island 30 *cassu* from the land, is now probably represented by *Bunder Dellim*.

The civilization of southern Elam was of very great antiquity. The Accadai or "Highlanders," who founded the cities and civilization of primordial Chaldea, descended from its mountains, carrying with them the picture-writing which afterwards developed into the cuneiform syllabary. An examination of the syllabary shows us that the only animals with which they were acquainted were the ass, the ox, the sheep, the gazelle, the antelope, the bear, the wild bull, the dove, the snake, the fly, the flea, the moth, the bee, and different species of fish,—horses, called the "animals of the east," being a subsequent importation. Neither the palm nor the vine were known before their emigration into Babylonia; indeed, Strabo states that the vine was first introduced into Susiana by the Macedonians. The different tribes of the country were constantly invading Babylonia, and from time to time imposed their dominion upon it. About 2280 B.C. (according to the date furnished by Assur-bani-pal), the Elamite king Cudur-nankhundi carried away the image of the goddess Nana from Babylonia to Shushan, and in Gen. xiv. we find Chedorlaomer or Cudur-lagamar, suzerain of the Babylonian princes. Cudur-nabug, the son of Simti-Silkhak, king of Yamutbal, founded a dynasty in Chaldea, which lasted for two generations, his son Rim-Agu or Eri-Acu (Arioch) of Larsa being afterwards conquered by Khammuragas. Khammuragas himself was a Cassite, and the dynasty he founded at Babylon, which he made for the first time the capital of the country, continued for several centuries, and was only overthrown at last by the Assyrian monarch, Tiglath-Aidar, in 1270 B.C. Another Cassite dynasty had ruled Babylonia at a very much earlier time, and one of its kings, Agu-kak-rimi, had restored the great temple of Bel at Babylon. Elamite raids recommenced within a few years after the overthrow of the second Cassite dynasty, Elamites from time to time appear as kings of Babylonia, and about 1200 B.C. the

whole country was ravaged and desolated by the Elamite Cudur-nankhundi II. Revenge for this, however, was shortly afterwards taken by the Babylonian Nebuchadnezzar. Subsequently, we find Elam and Babylon in alliance against the growing power of Assyria, and in the 8th and 7th centuries B.C., when Babylonia was alternately under the sway of the Assyrian princes and of Chaldean and other adventurers from the districts on the Persian Gulf, Elam played a large part in its political history. Tiglath-Pileser II., in 745 B.C., first overran the sea-coast as far as the Ukeni, and in 721 Sargon met Khumbanigas the elamite in battle at Duran, and drove him across the Assyrian frontier. After the establishment of the Assyrian empire in the west and north, the reduction of Babylonia to a dependent province became a necessity, and this involved the weakening and final conquest of the powerful kingdom of Elam itself. The struggle lasted through the reigns of four Assyrian kings, Sargon, Sennacherib, Esarhaddon, and Assur-bani-pal, and the overthrow of Elam was eventually effected only by the help of internal discord and civil war. In 710, Sutrak-nankhundi was driven from Yatbur and Rasi, on the Babylonian frontier, and his Babylonian ally Merodach-baladan left to his fate. In 704 the Elamites and Babylonians were defeated at Cis by Sennacherib, and in the following year the Cassi in the north-east were reduced to submission. In 697 B.C., the fleet of Sennacherib pursued Merodach-baladan and his followers to Nagitu and Khilman, at the mouth of the Eulæus, where the Elamites had given them shelter; the emigrants and their Susian allies were scattered, and the towns burned. Meanwhile, Cudur-nankhundi, the Elamite monarch, had marched into Babylonia; he was driven back, however, by Sennacherib, 34 of his cities were destroyed, and he himself fled from Madaktu to Khidaltu. Three months after he died, and his brother and successor, Umman-nunan, at once began to collect allies from all sides, and to prepare for resistance. The terrible defeat at Khidaltu in 692, however, broke the power of Elam, and made Babylonia an Assyrian province. Umman-aldas I. remained on friendly terms with Esarhaddon, but his murder by his two brothers, Urtaki and Temman, caused the war-party to recover its ascendancy, and Urtaki made an unsuccessful raid into Babylonia. On his death, his brother Temman succeeded, in virtue of the law by which the crown passed to the brother and not to the sons of the deceased monarch, and almost immediately provoked a quarrel with Assur-bani-pal by demanding the surrender of his nephews, who had taken refuge at the Assyrian court. The Assyrians followed the Elamite army to Shushan, where a battle was fought on the Eulæus, in which the Elamites were defeated, Temman was captured and slain, and Umman-igaz, the son of Urtaki, made king, his younger brother Tammaritu being assigned the district of Khidaltu. Umman-igaz afterwards assisted in the revolt of Babylonia, but Tammaritu raised a rebellion against him, defeated him in battle, cut off his head, and seized the crown. Tammaritu marched to Babylonia, while there, his officer Indabigas, made himself king at Shushan, and drove Tammaritu to the coast, where he fled to Assur-bani-pal. Indabigas was himself defeated and killed by a new pretender, Umman-aldas II., who was opposed, however, by three other rivals, two of whom maintained themselves in the mountains until the Assyrian conquest of the country, when Tammaritu was first restored and then imprisoned, Elam being wasted with fire and sword. The return of Umman-aldas led to a fresh Assyrian invasion; the Elamite king fled from Madaktu to Dur-umshak, Shushan and other cities were taken, and the Elamites utterly routed on the banks of the Itte. The whole country was reduced to a desert, Shushan was plundered and razed to the ground, 32 statues of its kings "of silver, gold, bronze, and alabaster" being carried off, and Susiana was made an Assyrian province in 609 B.C. The language of the Hebrew prophets seems to imply that Elam recovered its independence, but was again conquered by Nebuchadnezzar; on the fall of the Babylonian empire it passed to Persia, the Susian king Abradatas, mentioned in Xenophon's romance of the *Cyropædia* (vi.), being probably undisturbed. Darius formed it into a satrapy, with a tribute of 300 talents (Hdt. iii. 91). Shushan or Susa was rebuilt, and became the capital of the empire. Twice at least, however, the Susians attempted to revolt in the early part of the reign of Darius, under Artabanus, Atrines, the son of Umbadara, and Martiya, the son of Isan-daris, who called himself Immans; but they gradually came to be completely Aryanized, and their old agglutinative dialects were in course of time supplanted by the Aryan Persian dialects of the east.

Among the Elamite divinities may be mentioned Lagamar and Armannu, the secret title of Susa, "the god of Shushan," who was believed to go every year to Babylon. His oracle stood just outside the city, and his image was believed to be seen by the eyes of a mortal.

See Loftis, *Chaldaica*, p. 15, 1877, G. "In the *Persepolis* of the Oriental Company, 1844, and *Persepolis* of the British Museum, 1854, the cuneiform inscriptions of the Elamite kings are given in the *Persepolis* of the British Museum, 1854, 1874.

ELAND (*Boselaphus oreas*) is the largest and most valuable member of the antelope family. It is fully equal to the horse in size, standing six feet high at the shoulders, and measuring nine feet from the nose to the root of the tail. In robustness of build it resembles the ox, and forms the type of the bovine subdivision of antelopes. Its neck is thick, and is furnished with a prominent dewlap, fringed with long hair. Except on the ridge of the back the fur is short, and is usually of a reddish fawn colour above and white beneath. Its horns are about 20 inches in length, nearly straight, and in the male are surrounded throughout the greater part of their length with a spiral wreath, in the female they are more slender, and the spiral ridge is indistinct or absent. The eland is a native of South Africa, where it roams in considerable herds over the open plains, "rejoicing," says a recent traveller, "in the belts of shaded hillocks, and in the isolated groves of *Acacia capensis*, which, like islands in the ocean, are scattered over many of the stony and gravelly plains of the interior." It is slow in its movements as compared with the other antelopes, and is readily captured, while in disposition it is exceedingly gentle, and thus seems eminently adapted for domestication. It breeds readily in confinement, and herds of elands have already been introduced into various parks in Britain. Its flesh is highly prized as an article of food, resembling beef, it is said, in grain and colour, but being more delicate and better flavoured. The eland is remarkable for the quantity of fat which it takes on, exceeding in this respect all other large game. The carcase of a single individual weighs from 1500 to 2000 lbs. The eland was formerly abundant in the neighbourhood of Cape Town, but is now rarely found within the colony, and should man not succeed meanwhile in domesticating it, there is reason to fear that a valuable source of animal food will be lost to him by the speedy extermination of the eland.

EL-ARAIISH, L'ARAIISH, or in French **LARACHE**, a town of Morocco on the Atlantic coast, about 45 miles S. of Tangier, is picturesquely situated on a rocky height to the south of the embouchure of the Wady Loukhus or Lixus. It is the seat of a military governor, and has a number of well-kept though practically useless defences. The impress of Spanish occupation is still evident, and all the main points described in the 17th century by Pidon de Saint Olon can easily be distinguished—such as the church, the fort of St Jacques, the castle of St Etienne with its four cnpolas, the Jew's Tower, and the castle of Notre Dame d'Europe, now the Kasba or citadel. The market-place is surrounded with arcades of monolithic sandstone pillars. In spite of the bar at the entrance of the river preventing the passage of all vessels of more than 150 tons, the port is one of the most frequented on that part of the coast. The exports, gradually increasing in value, consist mainly of millet, drâ, and other cereals, canary-seed, beans, pease, cork, and wool. In 1875, 136 vessels entered and cleared, 26 being British and 58 Spanish. The population of the town at the same date was estimated at 5000, of whom nearly 4000 were Mahometans, about 1000 Spanish-speaking Jews, and 60 Christians.

Though the name of El-Araish is comparatively modern, and is mentioned neither by El-Bikri nor by Edrisi, it seems not improbable from a passage in Scylax that the site of the town was occupied by a Libyan settlement at an early date, and about 3½ miles up the river there still exist on the hill of Tchemmush very considerable ruins of the Punico-Roman city of Lixus. The modern town was finally taken from the Portuguese in 1689 by Mulei Ismael after a five months' siege; in 1786 it was attacked by the French, and in 1829 saw the destruction of the Morocco fleet by the Austrians. A convent in connection with the Spanish mission was maintained till 1822.

See Barth, *Wanderungen durch die Küstenländer des Mittelmeeres*, 1849; Rohlf's *Adventures in Morocco*, 1874; Tissot "Itinéraire de Tanger à R'bat," in *Bull. de la Soc. de Géogr.*, 1876.

ELASTICITY

1. **ELASTICITY** of matter is that property in virtue of which a body requires force to change its bulk or shape, and requires a continued application of the force to maintain the change, and springs back when the force is removed, and, if left at rest without the force, does not remain at rest except in its previous bulk and shape. The elasticity is said to be perfect when the body always requires the same force to keep it at rest in the same bulk and shape and at the same temperature through whatever variations of bulk, shape, and temperature it be brought. A body is said to possess some degree of elasticity if it requires any force to keep it in any particular bulk or shape. It is convenient to discuss elasticity of bulk and elasticity of shape sometimes separately and sometimes jointly.

2. Every body has some degree of elasticity of bulk. If a body possesses any degree of elasticity of shape it is called a solid, if it possesses no degree of elasticity of shape it is called a fluid.

3. All fluids possess elasticity of bulk to perfection. Probably so do all homogeneous solids, such as crystals and glasses. It is not probable that any degree of fluid pressure (or pressure acting equally in all directions) on a piece of common glass, or rock crystal, or of diamond, or on a crystal of bismuth, or of copper, or of lead, or of silver, would make it denser after the pressure is removed, or put it into a condition in which at any particular intermediate pressure it would be denser than it was at that pressure before the application of the extreme pressure. Malleable metals and alloys, on the other hand, may have their densities considerably increased and diminished by

hammering and by mere traction. By compression between the dies used in coining, the density of gold may be raised from 19·258 to 19·367, and the density of copper from 8·535 to 8·916,¹ and Mr M'Farlane's experiments quoted below (section 78), show a piece of copper wire decreasing in density from 8·91 to 8·835 after successive simple tractions, by which its length was increased from 287 centimetres to 317 centimetres, while its modulus of rigidity decreased from 443 to 426 million grammes per square centimetre. Later experiments, recently made for this article by the same experimenter, have shown *augmentation* of density from 8·85 to 8·95, produced by successive tractions which elongated a piece of copper wire from weighing 164 grammes per metre to weighing 135 grammes per metre, the wire having been first annealed by heating it to redness in sand, and allowing it to cool slowly. Augmentation of density by traction is a somewhat surprising result, but not altogether so when we consider that the wire had been reduced to an abnormally small density by the previous thermal treatment (the "annealing"). The common explanation of these changes of density in metals, which attributes them to porosity, is probably true, by porosity being understood a porous structure with such vast numbers of the ultimate molecules in the portions of the solid substance between pores or interstices that these portions may be called homogeneous in the sense that a crystal or a liquid can be called homogeneous (compare section 40 below).

¹ *Seventh Annual Report of the Deputy-Master of the Mint*, p. 43, quoting as authority Percy's *Metallurgy of Copper*. London, 1861.

4. The elasticity of shape of many solids is not perfect: it is not known whether it is perfect for any. It might be expected to be perfect for glass and rock crystal and diamond and other hard, brittle, homogenous substances; but experiment proves that at all events for glass it is not so, and shows on the contrary a notable degree of imperfection in the torsional elasticity of glass fibres. It might be expected that in copper and soft iron and other plastic metals the elasticity of shape would be very imperfect; experiment shows, on the contrary, that in copper, brass, soft iron, steel, platinum, provided the distortion does not exceed a certain limit in each case, elasticity of shape is remarkably perfect, much more perfect than in glass. It is quite probable that even in the softer metals—zinc, tin, lead, cadmium, potassium, sodium, &c.—the elasticity of shape may be as perfect as in the metals mentioned above, but within narrower limits as to degree of distortion. Accurate experiment is utterly wanting, to discover what is the degree of imperfection, if any, of the elasticity of any metal or alloy, when tested within sufficiently narrow limits of distortion.

5. The "viscosity of metals" described below (sections 21–25) does not demonstrate any imperfectness of elasticity according to the definition of section 1, which is purely statical. The viscosity of solids *may* (for all we yet know by experiment) depend, as does the viscosity of fluids, upon a resistance varying with the velocity of the change, and *vanishing when the velocity of the change is zero*, that is to say, when the body is at rest in any configuration; if so, the elasticity of the substance concerned is perfect within the limits of the experiment in question. If, on the other hand (as the discovery of elastic fatigue described below seems to indicate may be to some degree the case), the loss of energy from the vibrations in the experiments described is due to a dependence of the elastic resilient force upon previous conditions of the substance in respect to strain, the "viscosity" would be continuous with a true imperfectness of static elasticity. Here, then, we have a definite question which can be answered by experiment only:—Consider a certain definite stress applied to a solid substance; as, for example, a certain "couple" twisting a wire or rod; or a certain weight pulling it out, or compressing it lengthwise; or a certain weight placed on the middle of a beam supported by trestles under its ends. Let it be applied and removed a great many times, and suppose it to be seen that after each application and removal of the stress the body comes to rest in exactly the same configuration as after the previous application or removal of the stress. If now the body be left to itself with the stress removed, and if it be found to remain at rest in the same configuration for minutes, or hours, or days, or years after the removal of the stress, a part of the definition of perfect elasticity is fulfilled. Or, again, if the stress be applied, and kept applied with absolute constancy, and if the body remain permanently in a constant configuration, another item of the definition of perfect elasticity is proved. When any such experiment is made on any metal, unless some of the softer metals (section 4) is to be excepted, there is certainly very little if any change of configuration in the circumstances now supposed. The writer believes, indeed, that nothing of the kind has hitherto been discovered by experiment, provided the stress has been considerably less than that which would break or give a notable permanent twist, or elongation, or bend, to the body, that is to say, provided the action has been kept decidedly within the limits of the body's elasticity as commonly understood (sections 7–20). Mr J. T. Bottomley, with the assistance of a grant of money from the British Association, has commenced making arrangements for secular experiments on the elasticity of metals, in the tower of the

university of Glasgow, to answer this question in respect to permanence or non-permanence through minutes, or hours, or days, or years, or centuries. If several gold wires are hung side by side, one of them bearing the smallest weight that will keep it approximately straight, another wire $\frac{1}{10}$ of the breaking weight, another wire $\frac{2}{10}$ of the breaking weight, and so on; the one of them bearing $\frac{1}{10}$ of the breaking weight will probably, in the course of a few hours or days, show very sensible elongation. Will it go on becoming longer and longer till it breaks, or will the time-curve of its elongation be asymptotic? Even with considerably less than $\frac{1}{10}$ of the breaking weight there will probably be a continually augmenting elongation, but with asymptotic time-curve indicating a limit beyond which the elongation never goes, but which it infinitely nearly reaches in an infinite time. It is not probable that a gold wire stretched by $\frac{1}{10}$ of its present breaking weight, or by $\frac{1}{4}$ of its present breaking weight, or even by $\frac{1}{2}$ of its present breaking weight, would break in a thousand or in a million years. The existence of gold ornaments which have been found in ancient tombs and cities, and have preserved their shapes for thousands of years without running down glacier-wise (as does brittle pitch or sealing-wax in the course of a few years in moderately warm climates), seems to prove that for gold (and therefore leaves no doubt also for many other metals) the time-curve is asymptotic, if indeed there is any slow change of shape at all after the application of a moderate stress well within the limits of elasticity. Egyptian and Greek statues, Etruscan vases, Egyptian obelisks, and other stone monuments with their engraved hieroglyphics, flint implements and boulders, and mountains with the geological evidence we have of their antiquity, prove for stones, and pottery, and rocks of various kinds, a permanence for thousands and millions of years of resistance to distorting stress.

6. The complete fulfilment of the definition of perfect elasticity is not proved by mere permanence of the extreme configurations assumed by the substance when a stated amount of the stress is alternately applied and removed. This condition might be fulfilled, and yet the amount of elastic force might be different with the same palpable configuration of the body during gradual augmentation and during gradual diminution of the stress. That it is so in fact is proved by the discovery of viscosity referred to below; but it is not yet proved that if, after increasing the stress to a certain definite amount, the body is brought to rest in the same palpable configuration as before, the amounts of stress required to hold it in this configuration are different in the two cases. If they are (section 1) the elasticity is imperfect; if they are not the elasticity is perfect within the limits of the experiment (compare section 36 below).

7. LIMITS OF ELASTICITY.—*Elasticity of Shape.*—The degree of distortion within which elasticity of shape is found is essentially limited in every solid. Within sufficiently narrow limits of distortion every solid shows elasticity of shape to some degree—some solids to perfection, so far as we know at present. When the distortion is too great, the body either breaks or receives a permanent bend (that is, such a molecular disturbance that it does not return to its original figure when the bending force is removed). If the first notable dereliction from perfectness of elasticity is a breakage, the body is called brittle,—if a permanent bend, plastic or malleable or ductile. The metals are generally ductile; some metals and metallic alloys and compounds of metals with small proportions of other substances, are brittle; some of them brittle only in certain states of temper, others it seems essentially brittle. The steel of before the days of Bessemer and Siemens is a remarkable instance. When slowly cooled from a bright

red heat, it is remarkably tough and ductile. When heated to redness and cooled suddenly by being plunged in oil or water or mercury, it becomes exceedingly brittle and hard (glass-hard, as it is called), and to ordinary observation seems incapable of taking a permanent bend (though probably careful observation would prove it not quite so). The definition of steel used to be *approximately pure iron capable of being tempered glass-hard, and again softened to different degrees by different degrees of heat*. Now, the excellent qualities of iron made by Bessemer's and Siemens's processes are called steel, and are reckoned best when *incapable of being tempered glass-hard*, the possibility of brittleness supervening in the course of any treatment which the metal may meet with in its manufacture being an objection against the use of what was formerly called steel for ship's plates, ribs, stringers, &c., and for many applications of land engineering, even if the material could be had in sufficient abundance.

8 LIMITS OF ELASTICITY (CONTINUED)—*Elasticity of Bulk*.—If we reckon by the amount of pressure, there is probably no limit to the elasticity of bulk in the direction of increase of pressure for any solid or fluid; but whether continued augmentation produces continued diminution of bulk towards zero without limit, or whether for any or every solid or fluid there is a limit towards which it may be reduced in bulk, but smaller than which no degree of pressure, however great, can condense it, is a question which cannot be answered in the present state of science. Would any pressure, however tremendous, give to gold a density greater than 19.6, or to copper a density greater than 9.0, after the pressure is removed (section 3 above)? But whether the body be fluid or a continuous non-porous solid, it probably recovers the same density, however tremendously it may have been pressed, and probably shows perfect elasticity of bulk (section 3 above) through the whole range of positive pressure from zero to infinity, provided the pressure has been equal in all directions like fluid pressure. As for negative pressure, we have no knowledge of what limit, if any, there may be to the amount of force which can be applied to a body pulling its surface out equally in all directions. The question of how to apply the negative pressure is inextricably involved with that of the body's power to resist. The upper part of the mercury of a barometer adhering to the glass above the level corresponding to the atmospheric pressure is a familiar example of what is called negative pressure in liquids. Water and other transparent liquids show similar phenomena, another of which is the warming of water above its boiling point in an open glass or metal vessel varnished with shellac. Attempts to produce great degrees of this so-called negative pressure are baffled by what seems an instability of the equilibrium which supervenes when the negative pressure is too much augmented. It is a very interesting subject for experimental inquiry to find how high mercury or water or any other liquid can be got to stand above the level corresponding to the atmospheric pressure in a tall hermetically sealed tube, and how many degrees a liquid can, with all precautions, be warmed above its boiling point. In each case it seems to be by a minute bubble forming and expanding somewhere at the boundary of the liquid, where it is in contact with the containing vessel, that the possible range of the negative pressure is limited, judging from what we see when we carefully examine a transparent liquid, or the surface of separation between mercury and glass, in any such experiment. The contrast of the amounts of negative pressure practically obtainable or obtained hitherto in such experiments on liquids (which are at the most those corresponding to the weight of a few metres of the substance), with that obtainable in the case of even the weakest solids, is remarkable, and as for the strongest,

consider for instance (sec. 22 below) 17 nautical miles of steel pianoforte wire hanging by one end. When a cord, or rod, or wire of any solid substance hangs vertically, the negative pressure (for example, 23,000 atmospheres in the case just cited) in any transverse section is equal to the weight of the part hanging below it. It is an interesting question not to be answered by any experiment easily made or even devised,—How much would the longitudinal pull which can be applied to a cord, rod, or wire without breaking it be augmented (probably augmented, but possibly diminished) by lateral pull applied all round the sides so as to give equal negative pressure in all directions?

9. LIMITS OF ELASTICITY (CONTINUED)—*Elasticity of Shape for Distortions not Uniform through the Substance, and for Compound Distortions, and Elasticity corresponding to Co-existent Distortion and Change of Bulk*.—

Example 1—A round wire twisted, or a cylindrical shaft transmitting revolutional motive in machinery, presents, as we shall see (sec. 64), an instance of simple distortion, but to different degrees in different parts of the substance, increasing from the axis where it is zero, uniformly to the surface where it is greatest.

Example 2—Elongation of a wire or rod by direct pull, is (sec. 23) an instance of a compound distortion co-existing with a rarefaction of the substance, both distortion and rarefaction uniform throughout.

Example 3—Shortening of a column by end pressure is an instance of a similar compound distortion combined with condensation of the substance, both distortion and condensation uniform throughout.

Example 4—Flexure of a round wire or of a bar, or beam, or girder, of any shape of normal section, by opposite bending couples applied at the two ends, is an instance in which one-half of the substance is stretched, and the other half shortened with exactly the same combination of distortions and changes of bulk as in examples 2 and 3. The strain is uniform along the length of the bar, but varies in the cross section in simple proportion to distance from a certain line (sec. 62) through the centre of gravity of the sectional area, which, in the case of a round bar, is the diameter perpendicular to the plane of curvature.

The limits of elasticity in the cases of these four examples are subjects of vital importance in practical mechanics, and a vast amount of careful and accurate observation and experiment, which has given much valuable practical information regarding them, has been gone through by engineers, in their necessary dealings with questions regarding strength of materials. Still there is great want of definite scientific information on the subject of limits of elasticity generally, and particularly on many elementary questions (section 21 below), which force themselves upon us when we endeavour to analyze the molecular actions concerned in such cases as the four examples now before us. Some principles of much importance for guidance in practical as well as theoretical deductions from observations and experiments on this subject were set forth twenty-nine years ago by Professor James Thomson, in an article published in the *Cambridge and Dublin Mathematical Journal* for November 1848. Nothing is to be gained either in clearness or brevity by any other way of dealing with it than reproducing it *in extenso*. It is accordingly given here, with a few changes made in it with its author's concurrence.

It constitutes the following sections, 10–20.

“On the strength of materials, as influenced by the existence or non-existence of certain mutual strains among the particles composing them. By James Thomson, M.A., College, Glasgow

10 “My principal object in the following paper is to show that the absolute strength of any material composed of a substance possessing ductility (and few substances, if any, are entirely devoid of this property) may vary to a great extent, according to the state of tension or relaxation in which the particles have been made to exist when the material as a whole is subject to no external strain

11. “Let, for instance, a round bar of malleable iron, or a piece of iron wire, be made red hot, and then be allowed to cool. Its

¹ [Note added Nov. 1877] More nearly what is now called stress than what is now called strain is meant by “strain” in this article, which was written before Rankine's introduction of the word stress, and distinct definition of the word strain (see chap. I. of Mathematical Theory below).

particles may now be regarded as being all completely relaxed. Let, next, one end of the bar be fixed, and the other be made to revolve by torsion, till the particles at the circumference of the bar are strained to the utmost extent of which they can admit, without undergoing a permanent alteration in their mutual connexion.¹ In this condition, equal elements of the cross section of the bar afford resistances proportional to the distances of the elements from the centre of the bar; since the particles are displaced from their positions of relaxation through spaces which are proportional to the distances of the particles from the centre. The couple which the bar now resists, and which is equal to the sum of the couples due to the resistances of all the elements of the section, is that which is commonly assumed as the measure of the torsional strength of the bar. For future reference, this couple may be denoted by L , and the angle through which it has twisted the loose end of the bar by θ .

12. "The twisting of the bar may, however, be carried still farther, and during the progress of this process the outer particles will yield in virtue of their ductility, those towards the interior successively reaching their elastic limits, until, when the twisting has been sufficiently continued, all the particles in the section, except those quite close to the centre, have been strained beyond their elastic limits. Hence, if we suppose² that no change in the hardness of the substance composing the material has resulted from the sliding of its particles past one another, and that therefore all small elements of the section of the bar afford the same resistance, no matter what their distances from the centre may be, it is easy to prove that the total torsional resistance of the bar is $\frac{2}{3}$ of what it was in the former case; or, according to the notation already adopted, it is³ now $\frac{2}{3}L$.

13. "If, after this, all external stress be removed from the bar, it will assume a position of equilibrium, in which the outer particles will be strained in the direction opposite to that in which it was twisted, and the inner ones in the same direction as that of the twisting, the two sets of opposite couples thus produced among the particles of the bar balancing one another. It is easy to show that the line of separation between the particles strained in one direction and those in the other is a circle whose radius is $\frac{2}{3}$ of the radius of the bar. The particles in this line are evidently subject to no strain⁴ when no external couple is applied. The bar

¹ "I here assume the existence of a definite 'elastic limit,' or a limit within which, if two particles of a substance be displaced, they will return to their original relative positions when the disturbing force is removed. The opposite conclusion, to which Mr Hodgkinson seems to have been led by some interesting experimental results, will be considered at a more advanced part of this paper."

² [Note added October 1877.] This supposition may be true for some solids; it is certainly not true for solids generally. A piece of copper or of iron taken in a soft and unstrained condition certainly becomes "harder" when strained beyond its first limits of elasticity, that is to say, its limits of elasticity become wider; and a similar result will probably be found in ductile metals generally. Thus the resistance of the outer elements will be greater than those of the inner elements in the case described in the text, until the torsion has been pushed so far as to bring about the greatest hardness in all the elements at any considerable distance from the axis. It may be that before this condition has been attained the hardening of the outer elements will have been overdone, and they may have begun to lose strength, and to have become friable and fissured. The principle set forth in the text is not, however, vitiated by the incorrectness of a supposition introduced merely for the sake of numerical illustration.

³ "To prove this, let r be the radius of the bar, η the utmost force of a unit of area of the section to resist a strain tending to make the particles slide past one another, or to resist a shearing strain, as it is commonly called. Also, let one section of the bar be supposed to be divided into an infinite number of concentric annular elements, the radius of any one of these being denoted by x and its area by $2\pi x dx$.

"Now, when only the particles at the circumference are strained to the utmost, and when, therefore, the forces on equal areas of the various elements are proportional to the distances of the elements from the centre, we have $\eta \frac{x}{r}$ for the force of a unit of area at the distance of x from the centre. Hence the total tangential force of the element is

$$= 2\pi x dx \cdot \eta \frac{x}{r},$$

and the couple due to the same element is

$$= x \cdot 2\pi x dx \cdot \eta \frac{x}{r} = 2\pi \eta \frac{1}{r} x^3 dx;$$

and therefore the total couple, which has been denoted above by L , is

$$= 2\pi \eta \frac{1}{r} \int_0^r x^3 dx,$$

that is

$$L = \frac{2}{3} \pi \eta r^3 \dots \dots \dots (a).$$

Next, when the bar has been twisted so much that all the particles in its section afford their utmost resistance, we have the total tangential force of the element $2\pi x dx \cdot \eta$, and the couple due to the same element

$$= x \cdot 2\pi x dx \cdot \eta = 2\pi \eta x^2 dx.$$

Hence the total couple due to the entire section is

$$= 2\pi \eta \int_0^r x^2 dx = \frac{2}{3} \pi \eta r^3.$$

But this quantity is $\frac{2}{3}$ of the value of L in formula (a). That is, the couple which the bar resists in this case is $\frac{2}{3}L$, or $\frac{2}{3}$ of that which it resisted in the former case."

⁴ "Or at least they are subject to no strain of torsion, either in the one direction or in the other; though they may be subject to a strain of compression or ex-

with its new molecular arrangement may now be subjected, as often as we please,⁵ to the couple $\frac{2}{3}L$ without undergoing any farther alteration. Its strength to resist torsion, in the direction of the couple L has therefore been considerably increased. Its strength to resist torsion in the opposite direction has, however, by the same process, been much diminished; for as soon as its free extremity has been made to revolve backwards through an angle⁶ of $\frac{2}{3}\theta$ from the position of equilibrium, the particles of the circumference will have suffered the utmost distortion of which they can admit without undergoing permanent alteration. Now, it is easy to prove that the couple required to produce a certain angle of torsion is the same in the new state of the bar as in the old.⁷ Hence the ultimate strength of the bar when twisted backwards is represented by a couple amounting to only $\frac{1}{3}L$. But, as we have seen, it is $\frac{2}{3}L$ when the wire is twisted forwards. This is, then, *The wire in its new state has twice as much strength to resist torsion in one direction as it has to resist at the other.*

14. "Principles quite similar to the foregoing, are applicable in regard to beams subjected to cross strain. As, however, my chief object at present is to point out the existence of such principles, to indicate the mode in which they are to be applied, and to show their great practical importance in the determination of the strength of materials, I need not enter fully into their application in the case of cross strain. The investigation in this case closely resembles that in the case of torsion, but is more complicated on account of the different ultimate resistances afforded by any material to tension and to compression, and on account of the numerous varieties in the form of section of beams which for different purposes it is found advisable to adopt. I shall therefore merely make a few remarks on this subject.

15. "If a bent bar of wrought iron or other ductile material be straightened, its particles will thus be put into such a state that its strength to resist cross strain, in the direction towards which it has been straightened, will be very much greater than its strength to resist it in the opposite direction, each of these two resistances being entirely different from that which the same bar would afford were its particles all relaxed when the entire bar is free from external strain. The actual ratios of these various resistances depend on the comparative ultimate resistances afforded by the substance to compression and extension, and also, in a very material degree, on the form of the section of the bar. I may, however, state that in general the variations in the strength of a bar to resist cross strain, which are occasioned by variations in its molecular arrangement, are much greater even than those which have already been pointed out as occurring in the strength of bars subjected to torsion.

16. "What has already been stated is quite sufficient to account for many very discordant and perplexing results which have been arrived at by different experimenters on the strength of materials. It scarcely ever occurs that a material is presented to us, either for experiment or for application to a practical use, in which the particles are free from great mutual strains. Processes have already been pointed out by which we may at pleasure produce certain peculiar strains of this kind. These, or other processes producing somewhat similar strains, are used in the manufacture of almost all materials. Thus, for instance, when malleable iron has received its final conformation by the process termed *cold chiseling*, that is, by hammering it till it is cold, the outer particles exist in a state of extreme compression, and the internal ones in a state of extreme tension. The same seems to be the case in cast iron when it is taken from the mould in which it has been cast. The outer portions have cooled first, and have therefore contracted, while the inner ones still continued expanded by heat. The inner ones then contract as they subsequently cool, and thus they, as it were, pull the outer ones together. That is, in the end the outer ones are in a state of compression and the inner ones in the opposite condition.

17. "The foregoing principles may serve to explain the true

ension in the direction of the length of the bar." [That they are so is proved by experiments made for the present article by Mr Thomson (see October 1877). "This, however, does not fall to be considered in the investigation of the text."

⁵ "This statement, if not strictly, is at least extremely nearly true, since from the experiments made by Mr Fairbairn and Mr Hodgkinson on cast iron (see various Reports of the British Association), we may conclude that the particles are influenced only in an extremely slight degree by time. Were the particles composed of some substance such as sealing wax, or hard pitch, possessing a considerable amount of elasticity, the statement in the text would not hold good."

⁶ [Note added October 1877.] This assumes that the limits of elasticity of a substance which has already been strained beyond its limits of elasticity are equal on the two sides of the shape which it has when in equilibrium without any disturbing force—a supposition which may be true or may not be true. Its permanent is urgently needed to test it; for its truth or falseness is a matter of much importance in the theory of elasticity.

⁷ "To prove this, let the bar be supposed to be divided into an infinite number of elementary concentric tubes (like the small annual rings of growth in trees). To twist each of these tubes through a certain angle the same amount of force will be required, whether the tube is already twisted or not. Hence to twist the entire bar through a certain angle, through a certain number of elementary tubes, will be the same thing, to twist the whole bar through a certain angle, or to twist a couple will be required whether the various elementary tubes be all twisted or all relaxed, when the bar as a whole is free from external strain."

cause of an important fact observed by Mr Eaton Hodgkinson in his valuable researches in regard to the strength of cast iron (*Report of the British Association for 1837*, p. 362)¹. He found, that, contrary to what had been previously supposed, a strain, however small in comparison to that which would occasion rupture, was sufficient to produce a set, or permanent change of form, in the beams on which he experimented. Now this is just what should be expected in accordance with the principles which I have brought forward, for if, for some of the causes already pointed out, various parts of a beam previously to the application of an external force have been strained to the utmost, when, by the application of such force, however small, they are still farther displaced from their positions of relaxation, they must necessarily undergo a permanent alteration in their connexion with one another, an alteration permitted by the ductility of the material; or, in other words, the beam as a whole must take a set.

18 "In accordance with this explanation of the fact observed by Mr Hodgkinson, I do not think we are to conclude with him that 'the maxim of loading bodies within the elastic limit has no foundation in nature'. It appears to me that the defect of elasticity, which he has shown to occur even with very slight strains, exists only when the strain is applied for the first time, or, in other words, that if a beam has already been subjected to a considerable strain, it may again be subjected to any smaller strain in the same direction without its taking a set. It will readily be seen, however, from Mr Hodgkinson's experiments, that the term 'elastic limit,' as commonly employed, is entirely vague, and must tend to lead to erroneous results.

19 "The considerations adduced seem to me to show clearly that there really exist two elastic limits for any material, between which the displacements or deflexions, or what may in general be termed the changes of form, must be confined, if we wish to avoid giving the material a set, or, in the case of variable strains, if we wish to avoid giving it a continuous succession of sets which would gradually bring about its destruction, that these two elastic limits are usually situated one on the one side and the other on the opposite side of the position which the material assumes when subject to no external strain, though they may be both on the same side of this position of relaxation,² and that they may therefore with propriety be called the *superior* and the *inferior limits* of the change of form of the material for the particular arrangement which has been given to its particles, that these two limits are not fixed for any given material, but that, if the change of form be continued beyond either limit, two new limits will, by means of an alteration in the arrangement of the particles of the material, be given to it in place of those which it previously possessed; and lastly, that the processes employed in the manufacture of materials are usually such as to place the two limits in close contiguity with one another, thus causing the material to take in the first instance a set from any strain, however slight, while the interval which may afterwards exist between the two limits, and also, as was before stated, the actual position assumed by each of them are determined by the peculiar strains which are subsequently applied to the material.

20 "The introduction of new, though necessary, elements into the consideration of the strength of materials may, on the one hand, seem annoying from rendering the investigations more complicated. On the other hand, their introduction will really have the effect of obviating difficulties, by removing erroneous modes of viewing the subject, and preventing contradictory or incongruous results from being obtained by theory and experiment. In all investigations, in fact, in which we desire to attain or to approach nearly to truth, we must take facts as they actually are, not as we might be tempted to wish them to be for enabling us to dispense with examining processes which are somewhat concealed and intricate but are not the less influential from their hidden character."

21 Passing now to homogeneous matter (sec. 38), homogeneously strained (chap. II. of Math. Theory below),

¹ "For further information regarding Mr Hodgkinson's views and experiments see his communications in the *Transactions of the Sections of the British Association for the years 1843* (p. 29) and 1844 (p. 25), and a work by him, entitled *Experimental Researches on the Strength and other Properties of Cast Iron*, 8vo, 1846."

² "Thus if the section of a beam be of some such form as that shown in either of the accompanying figures, the one rib or the two ribs, as the case may be, being very weak in comparison to the thick part of the beam, it may readily occur that the two elastic limits of deflexion may be situated both on the same side of the position assumed by the beam when free from external force. For if the beam has been supported at its extremities and loaded at its middle till the rib A is yielded by its ductility so as to make all its particles exert their utmost tension, and if the load be now gradually removed, the particles at B may even be compressed to the utmost before the load has been entirely removed."

Fig. 1.

we are met by physical questions of great interest regarding limits of elasticity. Supposing the solid to be homogeneously distorted in any particular way to nearly the limit of its elasticity for this kind of distortion, will the limits be widened or narrowed by the superposition of negative or positive pressure equal in all directions producing a dilatation or a condensation? It seems probable that a dilatation would narrow the limits of elasticity, and a condensation widen them. This, however, is a mere guess: experiment alone can answer the question. Take again a somewhat less simple case. A wire is stretched by a weight to nearly its limits of longitudinal elasticity; a couple twisting it is applied to its lower end—Will this either cause the weight to run down and give the wire a permanent set, or break it? Probably,—yes; but experiment only can decide. The corresponding question with reference to a column loaded with a weight may have the same answer, but not necessarily so. Experiment again is wanting. A wire hanging stretched by a light weight, merely to steady it, is twisted to nearly its limit of torsional elasticity by a couple of given magnitude applied to its lower end—the stretching weight is increased—Will this cause it to yield to the couple and take a permanent set? Probably,—yes [Certainly yes, for steel piano-forte wire experimented on by Mr McFarlane to answer this question since it was first put in type for the present article] If so, then the limits of torsional elasticity of a wire bearing a heavy weight are widened by diminishing or taking off the weight; and no doubt it will follow continuously that a column twisted by opposing couples at its two ends will have its limits of torsional elasticity widened by the application of forces to its two ends, pressing them towards one another. Experiments to answer these questions would certainly reward the experimenter with definite and interesting results.

22. **NARROWNESS OF LIMITS OF ELASTICITY—Solids.**—The limit of elasticity of metals, stones, crystals, woods, are so narrow that the distance between any two neighbouring points of the substance never alters by more than a small proportion of its own amount without the substance either breaking or experiencing a permanent set, and therefore the angle between two lines meeting in any point of the substance and passing always through the same matter is never altered by more than a small fraction of the radian,³ before the body either breaks or takes a permanent set. By far the widest limits of elasticity hitherto discovered by experiment, for any substance except cork, india-rubber, jellies, are those of steel pianoforte wire. Take, for example, the piano-forte wire at present in use for deep-sea soundings. It is No. 22 of the Birmingham wire gauge, its density is 7.727, it weighs 0.34 gramme per centimetre, or 6.298 kilogrammes per nautical mile of 1852.3 metres, and therefore its sectional area and diameter are 0.044 square centimetre and .0244 centimetre. It bears a weight of 106 kilogrammes, which is equal in weight to about 31 kilometres of its length, and when this weight is alternately hung on and removed the length of the wire varies by $\frac{1}{80}$ of its amount. While this elongation takes place there is a lateral shrinking, as we shall see (section 47), of from $\frac{1}{4}$ to $\frac{3}{10}$ of the same amount.

23 Consider now in the unstrained wire two lines through the substance of the wire at right angles to one another in any plane through or parallel to the axis of the wire in directions equally inclined to this line. When the wire is pulled lengthwise the two vertical angles bisected by the length of the wire become acute, and the other two obtuse by a small difference, as illustrated in the diagram (fig. 2),

³ The radian is the angle whose arc is equal to radius, it is equal to 57°.29. ...

where the continuous lines represent a portion of the unpulled wire, and the dotted lines the same portion of the wire when pulled. The change in each of the angles would be $\frac{1}{80}$ of the radian in virtue of the elongation were there no lateral shrinking, and about $\frac{1}{320}$ of the radian in virtue of the lateral shrinking were there no elongation. The whole change experienced by each of the right angles is therefore actually (section 37) $\frac{1}{80} + \frac{1}{320}$, or about $\frac{1}{64}$ of the radian, or $0^{\circ}84$. This is an extreme case. In all other cases of metals, stones, glasses, crystals, the substance either breaks or takes a permanent bend, probably before it experiences any so great angular distortion as a degree: and except in the case of steel we may roughly regard the limits of elasticity as being something between $\frac{1}{1000}$ and $\frac{1}{100}$ in respect to the linear elongation or contraction, and from $\frac{1}{50}$ of a degree to half a degree in respect to angular distortion.

Fig. 2.

24. On the other hand, gelatinous substances, such as india-rubber and elastic jellies, have very wide limits of elasticity. A vulcanized india-rubber band, for instance, is capable of being stretched, again and again, to eight times its length, and returning always to nearly its previous condition when the stress is removed. A shape of transparent jelly presents a beautiful instance of great degrees of distortion with seemingly very perfect elasticity. All these instances, india-rubber and jellies, show with great changes of shape but slight changes of bulk. They have, in fact, all, as nearly as experiment has hitherto been able to determine, the same compressibility as water.

25. Cork, another body with very wide limits of elasticity (very imperfect elasticity it is true) is singular, among bodies seemingly homogeneous to the eye, in its remarkably easy compressibility. It is, in fact, the only seemingly homogeneous solid which shows to the unaided eye any sensible change of bulk under any practically applicable forces. A small homogeneous piece torn out of a cork may, by merely pressing it between the fingers, be readily compressed to half its bulk, and a large slab of cork in a Bramah press may be compressed to $\frac{1}{10}$ of its bulk. An ordinary bottle cork loaded with a small piece of metal presents a very interesting appearance in an Oersted glass compressing vessel; first floating, and when compressed to 20 or 30 atmospheres sinking, and shrivelling in bulk very curiously; then on the pressure being removed, expanding again, but not quite to previous bulk, and floating up or remaining down according to the amount of its load.

The divergencies presented by cork and gelatinous bodies in opposite directions from the regular elasticity of hard solids form an interesting subject, to which we shall return later (section 48).

26. *Liquids*.—In respect to liquids, there are no limits of elasticity so far as regards the magnitude of the positive pressure applied or conceivably applicable; but in respect to the magnitude of negative pressure, and in respect to the magnitude of the change of bulk, whether by negative or positive pressure, there are probably very decided and not very wide limits. Thus water, though condensed $\frac{1}{115}$ of its bulk by 2000 atmospheres in Porcius's¹ experiments corrected roughly for the compres-

sion of his glass "piezometer," which is very nearly at the rate of $\frac{1}{1100}$ per atmosphere found (section 75 below) more accurately by subsequent experiments for moderate pressures up to 20 or 30 atmospheres, may be expected to be compressed by much less than $\frac{1}{3}$ of its volume under a pressure of 7000 atmospheres. How much it or any other liquid is condensed by a pressure of 10,000 atmospheres, or by 20,000 atmospheres, is an interesting subject for experimental investigation.

27. *Gases*.—In respect to rarefaction, and in respect to proportionate condensation, gases present enormously wider limits of elasticity than any liquids or solids,—in fact no limit in respect to dilatation, and in respect to condensation a definite limit only when the gas is below Andrews's "critical temperature." If the gas be kept at any temperature above that critical temperature, it remains homogeneous, however much it be condensed; and therefore for a fluid above the critical temperature there is, in respect to magnitude of pressure, no superior limit to its elasticity. On the other hand, if a fluid be kept at any constant temperature less than its critical temperature, it remains homogeneous, and presents an increasing pressure until a certain density is reached; when its bulk is further diminished it divides into two parts of less and greater density (the part of less density being called vapour, that of greater density being called liquid, if it is not solid) and presents no further increase of pressure until the vaporous part shrinks to nothing, and the whole becomes liquid (that is to say, homogeneous fluid at the greater of the two densities) or else becomes solid—the question whether the more dense part is liquid or solid depending on the particular temperature below the critical temperature at which the whole substance is kept during the supposed experiment.

28. The thermo-dynamic reasoning of Professor James Thomson, which showed the effect of change of pressure in altering the freezing point of a liquid, leads to analogous considerations regarding the effect of continuous increase or continuous decrease of pressure upon a mass consisting of the same substance partly in the liquid and partly in the solid state at one temperature. The three cases of transition from gas to liquid, from gas to solid, and from liquid to solid, present us with perfectly definite limits of elasticity,—the only perfectly definite limits of elasticity in nature of which we have any certain knowledge.

29. *Viscosity of Fluids and Solids*.—Closely connected with limits of elasticity, and with imperfectness of elasticity, is viscosity, that is to say, resistance to change of shape depending on the velocity of the change. The full discovery of the viscosity of liquids and gases is due originally to Stokes; and his hypothesis that in fluids the force of resistance is in simple proportion to the velocity of change of shape has been subsequently confirmed by the experimental investigations of Helmholtz, Maxwell, Meyer, Kundt, and Warburg. The definition of a fluid given in section 2 above may, by section 1, be transformed into the following:—A fluid is a body which requires no force to keep it in any particular shape, or—A fluid is a body which exercises no permanent resistance to a change of shape. The resistance to a change of shape presented by a fluid, evanescent as it is when the shape is not being changed (or vanishing when the velocity of the change vanishes), is essentially different from that permanent resistance to change of shape, the manifestation of which in solids constitutes elasticity of shape as defined in section 1. Maxwell's admirable kinetic theory of the viscosity of gases points to a full explanation of viscosity, whether of gases, liquids, or solids, in the consideration of configurations and arrangements of relative motions of molecules, permanent in a solid under distorting stress, and temporary in fluids or solids while the shape is being changed, in

¹ *Transactions of Royal Society*, June 1826, "On the Progressive Compression of Water by high degrees of force, with some trials of its effects on other liquids," by J. Perkins. Communicated by W. H. Wollaston, M.D., V.P.R.S.

virtue of which elastic force in the quiescent solid, and viscous resistance to change of shape in the non-quiescent fluid or solid, are produced.

30. *Viscosity of Metals and Fatigue of their Elasticity.*—Experimental exercises performed by students in the physical laboratory of the university of Glasgow, during the session 1864–65, brought to light some very remarkable and interesting results, proving a loss of energy in elastic vibrators (sometimes as much as two or three per cent. of energy lost in the course of a single vibration in one direction) incomparably greater than anything that could be due to imperfections in their elasticity (section 1), and showing also a very remarkable fatigue of elasticity, according to which a wire which had been kept vibrating for several hours or days through a certain range came to rest much quicker when left to itself than when set in vibration after it had been at rest for several days and then immediately left to itself. Thus it was found that the rates of subsidence of the vibrations of the several wires experimented on were generally much less rapid on the Monday mornings, when they had been at rest since the previous Friday, than on other days of the week, or than after several series of experiments had been made on a Monday. The following statement (sections 31–34) is extracted from a short article by W. Thomson, in the *Proceedings of the Royal Society* for May 18, 1865, containing some of the results of these observations.

31. “*Viscosity.*—By induction from a great variety of observed phenomena, we are compelled to conclude that no change of volume or of shape can be produced in any kind of matter without dissipation of energy. Even in dealing with the *absolutely perfect* elasticity of volume presented by every fluid, and possibly by some solids, as for instance homogeneous crystals, dissipation of energy is an inevitable result of every change of volume, because of the accompanying change of temperature, and consequent dissipation of heat by conduction or radiation. The same cause gives rise necessarily to some degree of dissipation in connection with every change of shape of an elastic solid. But estimates founded on the thermodynamic theory of elastic solids, which I have given elsewhere,¹ have sufficed to prove that the loss of energy due to this cause is small in comparison with the whole loss of energy observed in many cases of vibration. I have also found, by vibrating a spring alternately in air of ordinary pressure and in the exhausted receiver of an air-pump, that there is an internal resistance to its motions immensely greater than the resistance of the air. The same conclusion is to be drawn from the observation made by Kupffer in his great work on the elasticity of metals, that his vibrating springs subsided much more rapidly in their vibrations than rigid pendulums supported on knife-edges. The subsidence of vibrations is probably more rapid in glass than in some of the most elastic metals, as copper, iron, silver, aluminium;² but it is much more rapid than in glass, marvellously rapid indeed, in some metals (as for instance zinc),³ and in india-rubber, and even in homogeneous jellies.

32. “The *frictional resistance* against change of shape must in every solid be infinitely small when the change of shape is made at an infinitely slow rate, since, if it were finite for an infinitely slow change of shape, there would be

infinite rigidity, which we may be sure⁴ does not exist in nature. Hence there is in elastic solids a *molecular friction* which may be properly called *viscosity of solids*, because, as being an internal resistance to change of shape depending on the rapidity of the change, it must be classed with fluid molecular friction, which by general consent is called *viscosity of fluids*. But, at the same time, it ought to be remarked that the word viscosity, as used hitherto by the best writers, when solids or heterogeneous semi-solid semi-fluid masses are referred to, has not been distinctly applied to molecular friction, especially not to the molecular friction of a highly elastic solid within its limits of high elasticity, but has rather been employed to designate a property of slow continual yielding through very great, or altogether unlimited, extent of change of shape, under the action of continued stress. It is in this sense that Forbes, for instance, has used the word in stating that ‘viscous theory of glacial motion,’ which he demonstrated by his grand observations on glaciers. As, however, he and many other writers after him have used the words plasticity and plastic, both with reference to homogeneous solids (such as wax or pitch even though also brittle, soft metals, &c.) and to heterogeneous semi-solid semi-fluid masses (as mud, moist earth, mortar, glacial ice, &c.), to designate the property common to all those cases of experiencing, under continued stress, either quite continued and unlimited change of shape, or gradually very great change at a diminishing (asymptotic) rate through infinite time, and as the use of the term *plasticity* implies no more than does *viscosity* any physical theory or explanation of the property, the word *viscosity* is without inconvenience left available for the definition I propose.

33. “To investigate the viscosity of metals, I have in the first place taken them in the form of round wires, and have chosen torsional vibrations, after the manner of Coulomb, for observation, as being much the easiest way to arrive at definite results. In every case one end of the wire was attached to a rigid vibrator with sufficient firmness (thorough and smooth soldering I find to be always the best plan when the wire is thick enough); and the other to a fixed rigid body, from which the wire hangs, bearing the vibrator at its lower end. I arranged sets of observations to be made for the separate comparison of the following cases:—

(a) “The same wire with different vibrators of equal weights to give equal stretching-tractions but different moments of inertia (to test the relation between viscous resistances against motions with different velocities through the same range and under the same stress).

(b) “The same wire with different vibrators of equal moments of inertia but unequal weights (to test the effect of different longitudinal tractions on the viscous resistance to torsion under circumstances similar in all other respects).

(c) “The same wire and the same vibrator, but different initial ranges in successive experiments (to test an effect unexpectedly discovered, by which the subsidence of vibrations from any amplitude takes place at very different rates according to the immediately previous molecular condition, whether of quiescence or of recurring changes of shape through a wider range).

(d) “Two equal and similar wires, with equal and similar vibrators, one of them kept as continually as possible in a state of vibration, from day to day; the other kept at rest, except when vibrated in an experiment once a day (to test the effect of continued vibration on the viscosity of a metal).

34. “*Results*—(a) It was found that the loss of energy in

¹ “On the Thermo-elastic Properties of Solids,” *Quarterly Journal of Mathematics*, April, 1855.

² We have no evidence that the precious metals are more elastic than copper, iron, or brass. One of the new bronze pennies gives quite as clear a ring as a two-shilling silver piece tested in the usual manner.

³ Torsional vibrations of a weight hung on a zinc wire subside so rapidly, that it has been found scarcely possible to count more than twenty of them in one case experimented on.

⁴ Those who believe in the existence of indivisible, infinitely strong and infinitely rigid, very small bodies (finite hard atoms!) deny this.

a single vibration through one range was greater the greater the velocity (within the limits of the experiments); but the difference between the losses at low and high speeds was much less than it would have been had the resistance been, as Stokes has proved it to be, in fluid friction, approximately as the rapidity of the change of shape. The irregularities in the results of the experiments which up to this time I have made seem to prove that much smaller vibrations (producing less absolute amounts of distortion in the parts of the wires most stressed) must be observed before any simple law of relation between molecular friction and velocity can be discovered.

(b) "When the weight was increased, the viscosity was always at first much increased; but then day after day it gradually diminished and became as small in amount as it had been with the lighter weight. It has not yet been practicable to continue the experiments long enough in any case to find the limit to this variation.

(c) "The vibration subsided in aluminium wires much more rapidly from amplitude 20 to amplitude 10, when the initial amplitude was 40, than when it was 20. Thus, with a certain aluminium wire, and vibrator No. 1 (time of vibration one way 1.757 second), the number of vibrations counted were in three trials—

Subsidence from 40 initial amplitude to 20	Vibrations.
And from 20 (in course of the same experiments) } to 10	56 64 64 96 98 96

The same wire and the same vibrator showed—
Subsidence from 20 initial amplitude to 10 } 112 vibrations.
(average of four trials)

Again, the same wire, with vibrator No. 2¹ (time of vibration one way 1.236), showed in two trials—

Subsidence from 40 initial amplitude to 20	Vibrations.
And continued from 20 to 10	54 52 90 90

Again, same wire and vibrator, —
From initial amplitude 20 to 10 . . . 103 (mean of eight trials).
This remarkable result suggested the question (d).

(d) "In a wire which was kept vibrating nearly all day, from day to day, after several days very much more molecular friction was found than in another kept quiescent except during each experiment. Thus two equal and similar pieces of copper wire were put up about the 26th of April, hanging with equal and similar lead weights, the upper and lower ends of the two wires being similarly fixed by soldering. No. 2 was more frequently vibrated than No. 1 for a few days at first, but no comparison of viscosities was made till May 15. Then

No. 1 subsided from 20 initial range to 10 in 97 vibrations.
No. 2 gave the same subsidence in 77 vibrations.

During the greater part of May 16 and 17, No. 2 was kept vibrating and No. 1 quiescent, and late on May 17 experiments with the following results were made:—

		Time per Vibration.
No 1 subsided from 20 to 10 after 99 vibrations in 237 secs.,		2.4
" " " 98 " 235 "		2.4
" " " 98 " 235 "		2.4
No 2 subsided from 20 to 10 after 58 vibrations in 142 "		2.45
" " " 60 " 147 "		2.45
" " " 57 " 139 "		2.45
" " " 60 " 147 "		2.45

[Addition, May 27, after the reading of the paper.]—No. 1 has been kept at rest from May 17, while No. 2 has been kept oscillating more or less every day till yesterday, May 26, when both were oscillated, with the following results:—

	Time per Vibration
No. 1 subsided from 20 to 10 after 100 vibrations in 242 secs.,	2.42
No 2 " " 44 or 45 vibrations	2.495

35. The investigation was continued with much smaller degrees of maximum angular distortion, to discover, if

possible, the law of the molecular friction, the existence of which was demonstrated by these experiments. Two questions immediately occurred:—What is the law of subsidence of range in any single series of oscillations, the vibrator being undisturbed by external force? and (question (a) of § 33 above) what is the relation between the law of subsidence in two sets of oscillations having different periods, with the same elastic body in the same circumstances of elastic force, as for instance the same or similar metallic wires with equal weights hung upon them, performing torsional oscillations in different times on account of the moments of inertia of the suspended masses being different?

36. So far as the irregularities depending on previous conditions of the elastic substance allowed any simple law to be indicated, the experimental answer to the first question for degrees of angular distortion much smaller than the palpable limits of elasticity was the COMPOUND INTEREST LAW, that is to say,—*The diminutions of range per equal intervals of time or per equal numbers of oscillations bore a constant proportion to the diminishing range; or, The differences of the logarithms of the ranges were proportional to the intervals of time.*

The only approach to an answer to the second question yet obtained is that the proportionate losses of amplitude in the different cases are not such as they would be if the molecular resistance were simply proportional to the velocity of change of shape in the different cases. If the molecular friction followed this simple law, the proportionate diminutions of range per period would be inversely as the periods, or per equal intervals of time they would be inversely as the squares of the periods. Instead of the proportion being so, the loss was greater with the longer periods than that calculated according to the law of square roots from its amount in the shorter periods. It was in fact as it would be if the result were wholly or partially due to imperfect elasticity, or "elastische Nach-wirkung"—elastic after-working—as the Germans call it (compare section 6 above). To form a rough idea of the results, irrespectively of the ultimate molecular theory (which is to be looked for in the proper extension of Maxwell's kinetic theory of viscosity of gases), consider a perfectly elastic vesicular solid, whether like a sponge with communications between the vesicles, or with each vesicle separately inclosed in elastic solid; imagine its pores and interstices filled up with a viscous fluid, such as oil. Static experiments on such a solid will show perfect elasticity of bulk and shape; kinetic experiments will show losses of energy such as are really shown by vibrators of india-rubber, jelly, glass, metals, or other elastic homogeneous solids, but more regular, and following more closely the compound interest law for single series and the law of relation to square roots of periods stated above for sets of oscillations in different periods. In short, according to Stokes's law of viscosity of fluids, our supposed vesicular vibrator would follow the law of subsidence of a simple vibrator experiencing a resistance simply proportional to the velocity of its motion, while no such simple law is applicable to the effects of the internal molecular resistance in a vibrating elastic solid.

37. *Hooke's Law.*—A law expressed by Hooke with Latin terseness in the words *Ut tensio sic vis* is the foundation of the mathematical theory of the elasticity of hard solids. By *tensio* here is meant not force (as is generally meant by the English word tension), but an elongation produced by force. In English, then, Hooke's law is that elongation (understood of an elastic solid) is proportional to the force producing it. It is, of course, to be extended continuously from elongation to contraction in respect to the effect, and from pull to push in respect

¹ Of same weight as No. 1, but different moment of inertia.

to the cause; and the experiments on which it is founded prove a perfect continuity from a pulling force to a smaller force in the same direction, and from the less force to zero, and from zero of pulling force to different degrees of push or positive pressure, or negative pull. Experimental proof merely of the *continuity of the phenomena through zero of force* suffices to show that, for *infinitely small* positive or negative pulls, positive or negative elongation is simply proportional to the positive or negative pull; or, in other words, positive or negative contraction is proportional to the positive or negative pressure producing it. But now must be invoked minutely accurate experimental measurement to find how nearly the law of simple proportionality holds through finite ranges of contraction and elongation. The answer happily for mathematicians and engineers is that *Hooke's law is fulfilled, as accurately as any experiments hitherto made can tell*, for all metals and hard solids each through the whole range within its limits of elasticity; and for woods, cork, india-rubber, jellies, when the elongation is not more than two or three per cent., or the angular distortion not more than a few hundredths of the radian (or not more than about two or three degrees). The same law holds for the condensation of liquids up to the highest pressures under which their compressibility has hitherto been accurately measured. [A decided but small deviation from Hooke's law has been found in steel pianoforte wire under combined influence of torsion and longitudinal pull by Mr McFarlane in experiments made for the present article after this section was in type. See section 81.]

Boyle's law of the "spring of air" shows that the augmentation of density of a gas is simply proportional to the augmentation of the pressure, through the very wide ranges of pressure through which that law is approximately enough fulfilled. Hence the infinitesimal diminution of volume produced by a given infinitesimal augmentation of pressure varies as the square of the volume, and the proportionate diminution of volume (that is to say, the ratio of the diminution of volume to the volume) is proportional to the volume, or inversely proportional to the density. Andrews's experiments on the compressibility of a fluid, such as carbonic acid, at temperatures slightly above the critical temperature, and of the gas and of liquids at temperatures slightly below the critical temperature, are intensely interesting, not merely in respect to the *natural history* of elasticity, but as opening vistas into the philosophy of molecular action.

We cannot expect to find any law of simple proportionality between stress and change of dimensions, or proportionate change of dimensions, in the case of any elastic or semi-elastic "soft" solids, such as cork on one hand or india-rubber or jellies on the other, when strained to large angular distortions, or to large proportionate changes of dimensions. The exceedingly imperfect elasticity of all these solids, and the want of definiteness of the substance of many of them, renders accurate experimenting unavailable for obtaining any very definite or consistent numerical results; but it is interesting to observe roughly the forces required to produce some of the great strains of which they are capable without any total break down of elastic quality; for instance, to hang weights successively on an india-rubber band and measure the elongations. This any one may readily do, and may be surprised to find the enormous increase of resistance to elongation presented by the attenuated band before it breaks.

38 Homogeneousness defined.—A body is called homogeneous when any two equal, similar parts of it, with corresponding lines parallel and turned towards the same parts, are undistinguishable from one another by any difference in quality. The perfect fulfilment of this condition, without any limit as to the smallness of the parts,

though conceivable, is not generally regarded as probable, for any of the real solids or fluids known to us, however seemingly homogeneous. It is held by all naturalists that there is a *molecular structure*, according to which, in *compound* bodies such as water, ice, rock-crystal, &c., the constituent substances lie side by side, or arranged in groups of finite dimensions, and even in bodies called *simple* (that is those not known to be chemically resolvable into other substances) there is no ultimate homogeneousness. In other words, the prevailing belief is that every kind of matter with which we are acquainted has a more or less *coarse-grained* texture, whether (as great masses of solid brick-work or stone-building, or as natural sandstone or granite rocks) having visible molecules, or (as seemingly homogeneous metals, or continuous crystals, or liquids, or gases) having molecules too small to be directly visible, or measurable but not *undiscoverably* small,—really, it is to be believed, of dimensions to be accurately determined in future advances of science. Practically the definition of *homogeneousness* may be applied on a very large scale to masses of building or coarse-grained conglomerate rock, or on a more moderate scale to blocks of common sandstone, or on a very small scale to seemingly homogeneous metals,¹ or on a scale of extreme, undiscovered fineness, to vitreous bodies, continuous crystals, solidified gums, as india-rubber, gum-arabic, &c., and fluids.

39. Isotropic and Æolotropic Substances defined.—The substance of a homogeneous solid is called *isotropic* when a spherical portion of it, tested by any physical agency, exhibits no difference in quality however it is turned. Or, which amounts to the same, a cubical portion, cut from any position in an isotropic body, exhibits the same qualities relatively to each pair of parallel faces. Or two equal and similar portions cut from *any* positions in the body, not subject to the condition of parallelism (section 38), are undistinguishable from one another. A substance which is not isotropic, but exhibits differences of quality in different directions, is called *æolotropic*.² The remarks of section 38 relative to homogeneousness in the aggregate, and the supposed ultimately heterogeneous texture of all substances, however seemingly homogeneous, indicate corresponding limitations and non-rigorous practical interpretations of isotropy and æolotropy.

40. Isotropy and Æolotropy of different sets of properties.—The substance of a homogeneous solid may be isotropic in one quality or class of qualities, but æolotropic in others. Or a transparent substance may transmit light at different velocities in different directions through it (that is, be *doubly-refracting*), and yet a cube of it may (and does in many natural crystals) show no sensible difference in its absorption of white light transmitted across it perpendicularly to any of its three pairs of faces. Or (as a crystal which exhibits *dichroism*) it may be sensibly æolotropic relatively to the absorption of light, but not sensibly double-refracting, or it may be dichroic and doubly-refracting, and yet it may conduct heat equally in all directions. Still, as a rule, a homogeneous substance which is æolotropic for one quality must be more than infinitesimally æolotropic for every quality which has directional character admitting of a corresponding æolotropy.

41. Modulus of Elasticity.—A modulus of elasticity is the number obtained by dividing the number expressing a stress³ by the number expressing the strain⁴ which it produces. A modulus is called a principal modulus when

¹ Which, however, we know, as proved by Deville and Van Troost, are porous enough at high temperatures to allow very free percolation of gases. Helmholtz and Root find percolation of platinum by hydrogen at ordinary temperature (*Berl. Sitzungsbericht*).

² Thomson and Tait's *Natural Philosophy*, section 676.

³ Mathematical Theory, below chap. I.

⁴ *Ibid.*

the stress is such that it produces a strain of its own type.

(1.) An isotropic solid has two principal modulus—*a modulus of compression* and *a rigidity*.

(2.) A crystal of the cubic class (fluor-spar, for instance) has three principal modulus,—*one modulus of compression* and *two rigidities*.

(3.) An anisotropic solid having (what no natural crystal has, but what a drawn wire has) perfect isotropy of physical qualities relative to all lines perpendicular to a certain axis of its substance has three principal modulus,—*two* determinable from its different compressibilities along and perpendicular to the axis, or from one compressibility and the “Young’s modulus” (section 42) of an axial bar of the substance, or determinable from two compressibilities; and *one rigidity* determinable by measurement of the torsional rigidity of a round axial bar of the substance.

(4.) A crystal of Iceland spar has four principal modulus,—three like those of case (3), and another rigidity depending on (want of complete circular symmetry, and) possession of *triple* symmetry of form, involving sextuple elastic symmetry, round the crystalline axis.

(5.) A crystal of the rectangular parallelepiped (or “tessal”) class has six distinct principal modulus which, when the directions of the principal axes are known, are determinable by six single observations,—three, of the three (generally unequal) compressibilities along the three axes; and three, of the three rigidities (no doubt generally unequal) relatively to the three simple distortions of the parallelepiped, in any one of which one pair of parallel rectangular faces of the parallelepiped become oblique parallelograms.

(6.) An anisotropic solid generally has six principal modulus,¹ which, when a piece of the solid is presented without information, and without any sure indication from its appearance of any particular axis or axes of symmetry of any kind, require just twenty-one independent observations for the determination of the fifteen quantities specifying their types, and the six numerical values of the modulus themselves.

42. “*Young’s Modulus*,” or *Modulus of Simple Longitudinal Stress*.—Thomas Young called the *modulus of elasticity* of an elastic solid the amount of the end-pull or end-thrust required to produce any infinitesimal elongation or contraction of a wire, or bar, or column of the substance multiplied by the ratio of its length to the elongation or contraction. In this definition the definite article is clearly misapplied. There are, as we have seen, two modulus of elasticity for an isotropic solid,—one measuring elasticity of bulk, the other measuring elasticity of shape. An interesting and instructive illustration of the confusion of ideas so often rising in physical science from faulty logic is to be found in “An Account of an Experiment on the Elasticity of Ice: By Benjamin Bevan, Esq., in a letter to Dr Thomas Young, Foreign Sec. R. S.” and in Young’s “Note” upon it, both published in the *Transactions of the Royal Society* for 1826. Bevan gives an interesting account of a well-designed and well-executed experiment on the flexure of a bar, 3.97 inches thick, 10 inches broad, and 100 inches long, of ice on a pond near Leighton Buzzard (the bar remaining attached by one end to the rest of the ice, but being cut free by a saw along its sides and across its other end), by which he obtained a fairly accurate determination of “the modulus of ice”;² and says that he repeated the experiment in various ways on ice bars of various dimensions, some remaining attached by

one end, others completely detached, and found results agreeing with the first as nearly “as the admeasurement of the thickness could be ascertained.” He then proceeds to compare “the modulus of ice” which he had thus found with “the modulus of water,” which he quotes from Young’s *Lectures* as deduced from Canton’s experiments on the compressibility of water. Young in his “Note” does not point out that the two modulus were essentially different, and that the *modulus of his definition*, the modulus determinable from the flexure of a bar, is essentially zero for every fluid. We now call “Young’s modulus” the particular modulus of elasticity defined as above by Young, and so avoid all confusion.

43. *Modulus of Rigidity*.—The “modulus of rigidity” of an isotropic solid is the amount of tangential stress divided by the deformation it produces,—the former being measured in units of force per unit of the area to which it is applied in the manner indicated by the annexed diagram (fig. 3), and the latter by the variation of each of the four right angles reckoned in fraction of the radian. By drawing either diagonal of the square in the diagram we see that the distorting stress represented by it gives rise to a normal traction on every surface of the substance perpendicular to the square and parallel to one of its diagonals, and an equal normal pressure on every surface of the solid perpendicular to the square and parallel to the other diagonal, and that the amount of each of these normal forces³ per unit of area is equal to the amount per unit area of the tangential forces which the diagram indicates. The corresponding⁴ geometrical proposition, also easily proved, is as follows: A strain compounded of a simple extension in one set of parallels, and a simple contraction of equal amount in any other set perpendicular to those, is the same as a simple shear in either of the two sets of planes cutting the two sets of parallels at 45°, and the numerical measuring of this shear or simple distortion is equal to double the amount of the elongation or contraction, each reckoned per unit of length.

Fig. 3.

Hence we have another definition of “modulus of rigidity” equivalent to the preceding:—The modulus of rigidity of an isotropic substance is the amount of normal traction or pressure per unit of area, divided by *twice* the amount of elongation in the direction of the traction or of contraction in the direction of the pressure, when a piece of the substance is subjected to a stress producing uniform distortion.

44.⁵ *Conditions fulfilled in Elastic Isotropy*.—To be elastically isotropic, a spherical or cubical portion of any solid, if subjected to uniform normal pressure (positive or negative) all round, must, in yielding, experience no deformation, and therefore must be equally compressed (or dilated) in all directions. But, further, a cube cut from any position in it, and acted on by tangential or distorting stress in planes parallel to two pairs of its sides, must experience simple deformation, or “shearing” parallel to either pair of these sides, unaccompanied by condensation or dilatation,⁶

³ The directions of these forces are called the “axes” of the stress. The corresponding directions in the corresponding strain are called the axes of the strain.

⁴ Mathematical Theory, chap. vi

⁵ This, with several of the following sections, 44–51, is borrowed, with but slight change, from the first edition of Thomson and Tait’s *Natural Philosophy*, by permission of the authors.

⁶ It must be remembered that the changes of figure and volume we are concerned with are so small that the principle of superposition is

¹ Mathematical Theory, chap. xvi.

² The result is given in the Table of Modulus, sec. 77, below.

and the same in amount for all the three ways in which a stress may be thus applied to any one cube, and for different cubes taken from any different positions in the solid. Hence the elastic quality of a perfectly elastic, homogeneous, isotropic solid is fully defined by two elements,—its resistance to distortion and its resistance to compression. The first has been already considered (section 43). The second is measured by the amount of uniform pressure in all directions per unit area of its surface required to produce a stated very small compression. The numerical reckoning of the first is the compressing pressure divided by the diminution of the bulk of a portion of the substance which, when uncompressed, occupies the unit volume. It is sometimes called the "*elasticity of bulk*," or sometimes the "*modulus of bulk-elasticity*," sometimes the *resistance to compression*. Its reciprocal, or the amount of compression on unit of volume divided by the compressing pressure, or, as we may conveniently say, the compression per unit of volume per unit of compressing pressure, is commonly called the *compressibility*.

45 *Strain produced by a single Longitudinal Stress* (subject of *Young's Modulus*).—Any stress whatever may¹ be made up of simple longitudinal stresses. Hence, to find the relation between any stress and the strain produced by it, we have only to find the strain produced by a single longitudinal stress, which, for an isotropic solid, we may do at once thus.—A simple longitudinal stress P is equivalent to a uniform dilating tension $\frac{1}{3}P$ in all directions, compounded with two distorting stresses, each equal to $\frac{1}{3}P$, and having a common axis in the line of the given longitudinal stress, and their other two axes any two lines at right angles to one another and to it. The diagram (fig 4), drawn in a plane through one of these latter lines and the former, sufficiently indicates the synthesis,—the only forces not shown being those perpendicular to its plane

Fig 4

Hence if n denote the *rigidity*, and k the *modulus of compression*, or the *modulus of bulk-elasticity* (being the same as the reciprocal of the compressibility), the effect will be an equal dilatation in all directions, amounting, per unit of volume, to

$$\frac{\frac{1}{3}P}{k} \dots \dots \dots (1),$$

compounded with two equal distortions, each amounting to

$$\frac{\frac{1}{3}P}{n} \dots \dots \dots (2),$$

and having (section 43, footnote) their axes in the directions just stated for the axes of the distorting stresses.

46. The dilatation and two shears thus determined may be conveniently reduced to simple longitudinal strains by following the indications of section 43, thus.—

The two shears together constitute an elongation amounting to $\frac{\frac{1}{3}P}{n}$ in the direction of the given force P , and equal contraction amounting to $\frac{\frac{1}{3}P}{n}$ in all directions perpendicular to it. And the cubic dilatation $\frac{\frac{1}{3}P}{k}$ implies a lineal dilatation, equal in all directions, amounting to $\frac{1}{9} \frac{P}{k}$.

¹ applicable; so that if any distorting stress produced a condensation, an opposite distorting stress would produce a dilatation, which is a violation of the isotropic condition.

² Mathematical Theory, chap viii.

On the whole, therefore, we have

$$\left. \begin{array}{l} \text{linear elongation} = P \left(\frac{1}{3n} + \frac{1}{9k} \right), \text{ in the direction of the} \\ \text{applied stress, and} \\ \text{linear contraction} = P \left(\frac{1}{6n} - \frac{1}{9k} \right), \text{ in all directions per-} \\ \text{pendicular to the applied stress.} \end{array} \right\} (3)$$

47. Hence "*Young's Modulus*" = $\frac{9nk}{3k+n}$, and when the ends of a column, bar, or wire of isotropic material are acted on by equal and opposite forces, it experiences a lateral lineal contraction equal to $\frac{3k-2n}{2(3k+n)}$ of the longitudinal dilatation, each reckoned as usual per unit of lineal measure. One specimen of the fallacious mathematics referred to in chap. xvi. of the mathematical theory below is a celebrated conclusion of Navier's and Poisson's that the ratio of lateral contraction to elongation by pull without transverse force is $\frac{1}{2}$. This would require the rigidity to be $\frac{2}{3}$ of the resistance to compression, for all solids; which was first shown to be false by Stokes² from many obvious observations, proving enormous discrepancies from it in many well-known bodies, and rendering it most improbable that there is any approach to a constancy of ratio between rigidity and resistance to compression in any class of solids. Thus clear elastic jellies and india-rubber present familiar specimens of isotropic homogeneous solids which, while differing very much from one another in rigidity ("stiffness"), are probably all of very nearly the same compressibility as water, which is about $\frac{1}{100000}$ per atmosphere. Their resistance to compression, measured by the reciprocal of this, is obviously many hundred times the absolute amount of the rigidity of the stiffest of those substances. A column of any of them, therefore, when pressed together or pulled out, within its limits of elasticity, by balancing forces applied to its ends (or an india-rubber band when pulled out), experiences no sensible change of volume, though very sensible change of length. Hence the proportionate extension or contraction of any transverse diameter must be sensibly equal to half the longitudinal contraction or extension; and such substances may be practically regarded as incompressible elastic solids in interpreting all the phenomena for which they are most remarkable. Stokes gave reasons for believing that metals also have in general greater resistance to compression, in proportion to their rigidities, than according to the fallacious theory, although for them the discrepancy is very much less than for the gelatinous bodies. This probable conclusion was soon experimentally demonstrated by Wertheim, who found the ratio of lateral to longitudinal change of lineal dimensions, in columns acted on solely by longitudinal force, to be about $\frac{1}{3}$ for glass and brass; and by Kirchhoff, who, by a well-devised experimental method, found .387 as the value of that ratio for brass, and .294 for iron. For copper it is shown to lie between .226 and .441, by experiments³ quoted below, measuring the torsional and longitudinal rigidities of copper wires.

48. All these results indicate rigidity less in proportion to the compressibility than according to Navier's and Poisson's theory. And it has been supposed by many naturalists who have seen the necessity of abandoning that theory as inapplicable to ordinary solids that it may be regarded as the proper theory for an ideal perfect solid, and as indicating an amount of rigidity not quite reached in any real substance, but approached to in some of the

² "On the Friction of Fluids in Motion, and the Equilibrium and Motion of Elastic Solids," *Trans. Camb. Phil. Soc.*, April 1845. See also *Camb. and Dub. Math. Jour.*, March 1848.

³ "On the Elasticity and Viscosity of Metals" (W. Thomson), *Proc. R. S.*, May 1865.

most rigid of natural solids (as, for instance, iron). But it is scarcely possible to hold a piece of cork in the hand without perceiving the fallaciousness of this last attempt to maintain a theory which never had any good foundation. By careful measurements on columns of cork of various forms (among them, cylindrical pieces cut in the ordinary way for bottles), before and after compressing them longitudinally in a Bramah's press, we have found that the change of lateral dimensions is insensible both with small longitudinal contractions and return dilatations, within the limits of elasticity, and with such enormous longitudinal contractions as to $\frac{1}{3}$ or $\frac{1}{2}$ of the original length. It is thus proved decisively that cork is much more rigid, while metals, glass, and gelatinous bodies are all less rigid, in proportion to resistance to compression, than the supposed "perfect solid"; and the practical invalidity of the theory is experimentally demonstrated. By obvious mechanism of jointed bars a solid may be designed which shall swell laterally when pulled, and shrink laterally when compressed, in one direction, and which shall be homogeneous in the same sense (article 40) as crystals and liquids are called homogeneous.

49. *Modulus of Simple Longitudinal Strain.*—In sections 45, 46, we examined the effect of a simple longitudinal stress in producing elongation in its own direction, and contraction in lines perpendicular to it. With stresses substituted for strains, and strains for stresses, we may apply the same process to investigate the longitudinal and lateral tractions required to produce a simple longitudinal strain (that is, an elongation in one direction, with no change of dimensions perpendicular to it) in a rod or solid of any shape.

Thus a simple longitudinal strain e is equivalent to a cubic dilatation e without change of figure (or linear dilatation $\frac{1}{3}e$ equal in all directions), and two distortions consisting each of dilatation $\frac{1}{3}e$ in the given direction and contraction $\frac{1}{3}e$ in each of two directions perpendicular to it and to one another. To produce the cubic dilatation e alone requires (section 44) a normal traction λe equal in all directions. And, to produce either of the distortions simply, since the measure (section 43) of each is $\frac{2}{3}e$, requires a distorting stress equal to $n \times \frac{2}{3}e$, which consists of tangential tractions each equal to this amount, positive (or drawing outwards) in the line of the given elongation, and negative (or pressing inwards) in the perpendicular direction. Thus we have in all

normal traction $-(\lambda + \frac{2}{3}n)e$, in the direction of the given strain, and
normal traction $-(\lambda - \frac{2}{3}n)e$, in every direction perpendicular to the given strain. } (4).

Hence the modulus of simple longitudinal strain is $\lambda + \frac{2}{3}n$.

50. *Weight-Modulus and Length of Modulus.*—Instead of reckoning moduli in units of force per unit of area, it is sometimes convenient to express them in terms of the weight of unit bulk of the solid. A modulus thus reckoned, or, as it is called by some writers, the length of the modulus, is of course found by dividing the weight-modulus by the weight of the unit bulk. It is useful in many applications of the theory of elasticity, as, for instance, in this result, which is proved in the elementary dynamics of waves in an elastic solid or fluid (chap. xvii. of the Mathematical Theory, below):—the velocity of transmission of longitudinal vibrations (as of sound) along a bar of cord, or of waves of simple distortion, or of simple longitudinal extension and contraction in a homogeneous

isotropic solid, or of sound waves in a fluid, is equal to the velocity acquired by a body in falling from a height equal to half the length of the proper modulus² for the case;—that is, the Young's Modulus $\left(\frac{9kn}{3\lambda + n}\right)$ for the first

case, the modulus of rigidity (n) for the second, the modulus of simple longitudinal strain $(\lambda + \frac{2}{3}n)$ for the third, the modulus of compression λ for the fourth. Remark that for air the static "length-modulus of compression" at constant temperature is the same as what is often technically called the "height of the homogeneous atmosphere."

51. In reckoning moduli there must be a definite understanding as to the unit in terms of which the force is measured, which may be either the *kinetic unit* or the *gravitation unit* for a specified locality, that is, the weight in that locality of the unit of mass. Experimenters hitherto have stated their results in terms in the gravitation unit, each for his own locality;—the accuracy hitherto attained being scarcely in any cases sufficient to require corrections for the different intensities of gravity in the different places of observation.

The most useful and generally convenient specification of the modulus of elasticity of a substance is in grammes-weight per square centimetre. This has only to be divided by the specific gravity of the substance to give the *length of the modulus*. British measures, however, being still unhappily sometimes used in practical and even in scientific statements, we too often meet with reckonings of the modulus in pounds per square inch or per square foot, in tons per square inch, or of length of the modulus in feet or in British statute miles.

The reckoning most commonly adopted in British treatises on mechanics and practical statements is pounds per square inch. The modulus thus stated must be divided by the weight of 12 cubic inches of the solid, or by the product of its specific gravity into .4335,³ to find the length of the modulus in feet.

To reduce from pounds per square inch to grammes per square centimetre, multiply by 70.31, or divide by .014223. French engineers generally state their results in kilogrammes per square millimetre, and so bring them to more convenient numbers, being $\frac{1}{100000}$ of the inco-

² In sections 73-76 we shall see that changes of temperature produced by the varying stresses cause changes of temperature which, in ordinary solids, render the velocity of transmission of longitudinal vibrations sensibly greater than that calculated by the rule stated in the text, if we use the *static modulus* as understood from the definition there given; and it will be shown how to take into account the thermal effect by using a definite *static modulus*, or *kinetic modulus*, according to the circumstances of any case that may occur.

³ This decimal being the weight in pounds of 12 cubic inches of water. The one great advantage of the French metrical system is that the mass of the unit volume (1 cubic centimetre) of water at its temperature of maximum density (3° 945 C) is unity (1 gramme) to a sufficient degree of approximation for almost all practical purposes. Thus, according to this system, the density of a body and its specific gravity mean one and the same thing; whereas on the British system the density is expressed by a number found by multiplying the specific gravity by one number or another, according to the choice of a cubic inch, pint, quart, wine gallon, imperial gallon, cubic foot, cubic yard, or cubic mile that is made for the unit of volume; and the grain, scruple, gunmaker's drachm, apothecary's drachm, ounce Troy, ounce avoirdupois, pound Troy, pound avoirdupois, stone (Imperial, Ayrshire, Lanarkshire, Dumbartonshire), stone for hay, stone for corn, quarter (of a hundredweight), quarter (of corn), hundredweight, or ton that is chosen for unit of mass. It is a remarkable phenomenon, belonging rather to moral and social than to physical science, that a people tending naturally to be regulated by common sense should voluntarily condemn themselves, as the British have so long done, to unnecessary hard labour in every action of common business or scientific work related to measurement, from which all the other nations of Europe have emancipated themselves. Professor W. H. Miller, of Cambridge, concludes, from a very trustworthy comparison of standards by Kupffer, of St. Petersburg, that the weight of a cubic decimetre of water at temperature of maximum density is 1000.013 grammes.

¹ It is to be understood that the vibrations in question are so much spread out through the *length* of the body that inertia does not sensibly influence the transverse contractions and dilatations which (unless the substance have in this respect the peculiar character presented by cork, section 48) take place along with them.

veniently large numbers expressing moduluses in grammes weight per square centimetre, but it is much better to reckon in millions of grammes per square centimetre.

52. "Resilience" is a very useful word, introduced about forty years ago (when the *doctrine of energy* was beginning to become practically appreciated) by Lewis Gordon, first professor of engineering in the university of Glasgow, to denote the quantity of work that a spring (or elastic body) gives back when strained to some stated limit and then allowed to return to the condition in which it rests when free from stress. The word "resilience" used without special qualification may be understood as meaning *extreme resilience*, or the work given back by the spring after being strained to the extreme limit within which it can be strained again and again without breaking or taking a permanent set. In all cases for which Hooke's law of simple proportionality between stress and strain holds, the resilience is obviously equal to the work done by a constant force of half the amount of the extreme force acting through a space equal to the extreme deflection.

53. When force is reckoned in "gravitation measure," resilience per unit of the spring's mass is simply the height that the spring itself, or an equal weight, could be lifted against gravity by an amount of work equal to that given back by the spring returning from the stressed condition.

54. Let the elastic body be a long homogeneous cylinder or prism with flat ends (a bar as we may call it for brevity), and let the stress for which its resilience is reckoned be *positive* normal pressures on its ends. The resilience per unit mass is equal to the greatest height from which the bar can fall with its length vertical, and impinge against a perfectly hard horizontal plane without suffering stress beyond its limits of elasticity. For in this case (as in the case of the direct impact of two equal and similar bars meeting with equal and opposite velocities, discussed in Thomson and Tait's *Natural Philosophy*, section 303), the kinetic energy of the translational motion preceding the impact is, during the first half of the collision, wholly converted into potential energy of elastic force, which during the second half of the collision is wholly reconverted into kinetic energy of translational motion in the reverse direction. During the whole time of the collision the stopped end of the bar experiences a constant pressure, and at the middle of the collision the whole substance of the bar is for an instant at rest in the same state of compression as it would have permanently if in equilibrium under the influence of that pressure and an equal and opposite pressure on the other end. From the beginning to the middle of the collision the compression advances at a uniform rate through the bar from the stopped end to the free end. Every particle of the bar which the compression has not reached continues moving uniformly with the velocity of the whole before the collision until the compression reaches it, when it instantaneously comes to rest. The part of the bar which at any instant is all that is compressed remains at rest till the corresponding instant in the second half of the collision.

55. From our preceding view of a bar impinging against an ideal perfectly rigid plane, we see at once all that takes place in the real case of any rigorously direct longitudinal collision between two equal and similar elastic bars with flat ends. In this case the whole of the kinetic energy which the bodies had before collision reappears as purely translational kinetic energy after collision. The same would be approximately true of any two bars, provided the times taken by a pulse of simple longitudinal stress to run through their lengths are equal. Thus if the two bars be of the same substance, or of different substances having the same value for Young's modulus, the lengths must be equal, but the diameters may be unequal. Or if the Young's

modulus be different in the two bars, their lengths must (Math. Theory, chap. xvii.) be inversely as the square roots of its values. To all such cases the laws of "collision between two perfectly elastic bodies," whether of equal or unequal masses, as given in elementary dynamical treatises, are applicable. But in every other case part of the translational energy which the bodies have before collision is left in the shape of vibrations after collision, and the translational energy after collision is accordingly less than before collision. The losses of energy observed in common elementary dynamical experiments on collision between solid globes of the same substance are partly due to this cause. If they were wholly due to it they would be independent of the substance, when two globes of the same substance are used. They would bear the same proportion to the whole energy in every case of collision between two equal globes, or again, in every case of collision between two globes of any stated proportion of diameters, provided in each case the two which collide are of the same substances; but the proportion of translational energy converted into vibrations would not be the same for two equal globes as for two unequal globes. Hence when differences of proportionate losses of energy are found in experiments on different substances, as in Newton's on globes of glass, iron, or compressed wool, this must be due to imperfect elasticity of the material. It is to be expected that careful experiments upon hard well-polished globes striking one another with such gentle forces as not to produce even at the point of contact any stress approaching to the limit of elasticity, will be found to give results in which the observed loss of translational energy can be almost wholly accounted for by vibrations remaining in the globes after collision.

56. *Examples of Resilience.*—*Example 1.*—In respect to simple longitudinal pull, the extreme resilience of steel pianoforte wire of the gauge and quality referred to in section 22 above (calculated by multiplying the breaking weight into half the elongation produced by it according to the experimental data of section 22) is 6066 metre-grammes (gravitation measure) per ten metres of the wire. Or, whatever the length of the wire, its resilience is equal to the work required to lift its weight through 179 metres.

Example 2.—The torsional resilience of the same wire, twisted in either direction as far as it can be without giving it any notable permanent set, was found to be equal to the work required to lift its weight through 1.3 metres.

Example 3.—The extreme resilience of a vulcanized india-rubber band weighing 12.3 grammes was found to be equal to the work required to lift its weight through 1200 metres. This was found by stretching it by gradations of weights up to the breaking weight, representing the results by aid of a curve, and measuring its area to find the integral work given back by the spring after being stretched by a weight just short of the breaking weight.

57. *Flexure of a Beam or Rod.*—In the problem of simple flexure a bar or uniform rod or wire, straight when free from stress, is kept in a circular form by equal opposing couples properly applied to its ends. The parts of the bar on the convex side of the circle must obviously be stretched longitudinally, and those on the concave side contracted longitudinally, by the flexure. It is not obvious, however, what are the conditions affecting the lateral shrinkings and swellings of ideal filaments into which we may imagine the bar divided lengthwise. Earlier writers had assumed without proof that each filament, bent as it is in its actual position in the bar, is elongated or contracted by the same amount as it would be if it were detached, and subjected to the same end pull or end compression with its sides quite free to shrink or

expand, but they had taken no account of the lateral shrinking or swelling which the filament must really experience in the bent bar. The subject first received satisfactory mathematical investigation from St Venant.¹ He proved that the old supposition is substantially correct, with the important practical exception of the flat spring referred to in section 59 below. His theory shows that, in fact, if we imagine the whole rod divided parallel to its length into infinitesimal filaments, each of these shrinks or swells laterally with sensibly the same freedom as if it were separated from the rest of the substance and subjected to end pull or end compression, lengthening or shortening it in a straight line to the same extent as it is really lengthened or shortened in the circular arc which it becomes in the bent rod. He illustrates the distortion of the cross section by which these changes of lateral dimensions are necessarily accompanied in the annexed diagram (fig. 5), in which either the whole normal section of a rectangular beam, or a rectangular area in the normal section of a beam of any figure, is represented in its strained and unstrained figures, with the central point O common to the two. The flexure is in planes perpendicular to YOY_1 , and is concave upwards (or towards X),—G, the centre of curvature, being in the direction indicated, but too far to be included in the diagram. The straight sides AC, BD, and all straight lines parallel to them, of the unstrained rectangular area become concentric arcs of circles concave in the opposite direction, their centre of curvature H being (articles 47, 48) for rods of india-rubber or gelatinous substance, or of glass or metal, from 2 to 4 times as far from O on one side as G is on the other. Thus the originally plane sides AC, BD of a rectangular bar become anticlastic² surfaces, of curvatures $\frac{1}{\rho}$ and

Fig. 5.

$-\frac{\sigma}{\rho}$, in the two principal sections, if σ denote the ratio of lateral shrinking to longitudinal extension. A flat rectangular, or a square, rod of india-rubber [for which σ amounts (section 47) to very nearly $\frac{1}{2}$, and which is susceptible of very great amounts of strain without utter loss of corresponding elastic action] exhibits this phenomenon remarkably well.

58. *Limits to the bending of Rods or Beams of hard solid substance.*—For hard solids, such as metals, stones, glasses, woods, ivory, vulcanite, papier-maché, elongations and contractions to be within the limits of elasticity must generally (section 23) be less than $\frac{1}{100}$. Hence the breadth or thickness of the bar in the plane of curvature must generally be less than $\frac{1}{100}$ of the diameter of curvature in order that the bending may not break it, or give it a permanent bend, or strain it beyond its "limits of elasticity."

59. *Exceptional case of Thin flat Spring, too much bent to fulfil conditions of section 57.*—St Venant's theory shows that a farther condition must be fulfilled if the ideal filaments are to have the freedom to shrink or expand as explained in section 57. For unless the breadth AC of the bar (or diameter perpendicular to the plane of flexure) be

very small in comparison with the mean proportional between the radius OH and the thickness AB the distances from YY_1 to the corners A', C', would fall short of the half thickness, OE, and the distances to B', D', would exceed it, by differences comparable with its own amount. This would give rise to sensibly less and greater shortenings and stretchings in the filaments towards the corners than those supposed in the ordinary calculation of flexural rigidity (article 61), and so vitiate the result. Unhappily, mathematicians have not hitherto succeeded in solving, possibly not even tried to solve, the beautiful problem thus presented by the flexure of a broad very thin band (such as a watch spring) into a circle of radius comparable with a third proportional to its thickness and its breadth.

60. But, provided the radius of curvature of the flexure is not only a large multiple of the greatest diameter, but also of a third proportional to the diameters in and perpendicular to the plane of flexure, then, however great may be the ratio of the greatest diameter to the least, the preceding solution is applicable; and it is remarkable that the necessary distortion of the normal section (illustrated in the diagram of article 57) does not sensibly impede the free lateral contractions and expansions in the filaments, even in the case of a broad thin lamina (whether of precisely rectangular section, or of unequal thicknesses in different parts).

61. *Flexural Rigidities of a Rod or Beam.*—The couple required to give unit curvature in any plane to a rod or beam is called its flexural rigidity for curvature in that plane. When the beam is of circular cross section and of isotropic material, the flexural rigidity is clearly the same, whatever be the plane of flexure through the axis, and the plane of the bending couple coincides with the plane of flexure. It might be expected that in a round bar of anisotropic material, such as a wooden rod with the annual woody layers sensibly plane and parallel to a plane through its axis, would show different flexural rigidities in different planes,—in the case of wood, for example, different according as the flexure is in a parallel or perpendicular to the annual layers. This is not so, however; on the contrary, it is easy to show, by an extension of St Venant's theory, that in the case of the wooden rod the flexural rigidity is equal in all planes through the axis, and that the plane of flexure always agrees with the plane of the bending couple, and to prove generally that the flexure of a bar of anisotropic substance, and composed it may be of longitudinal filaments of heterogeneous materials, is precisely the same as if it were isotropic, and that its flexural rigidities are calculated by the same rule from its Young's modulus, provided that the anisotropy is not such as (section 81) to give rise to alteration of the angle between the length and any diameter perpendicular to the length when weight is hung on the rod, or on any longitudinal filament cut from it. Excluding then all cases in which there is any such oblique anisotropy, we have a very simple theory for the flexure of bars of any substance, whether isotropic or anisotropic, and whether homogeneous or not homogeneous through the cross section.

62. *Principal Flexural Rigidities and Principal Planes of Flexure of a Beam.*—The flexural rigidity of a rod is generally not equal in different directions, and the plane of flexure does not generally coincide with the plane of the bending couple. Thus a flat ruler is much more easily bent in a plane perpendicular to its breadth than in the plane of its breadth; and if we apply opposing couples to its two ends in any plane through its axis not either perpendicular or parallel to its breadth, it is obvious that the plane in which the flexure takes place will be more inclined to the plane of the breadth than to the plane of the bending couple. Very elementary statical theory, founded on St

¹ *Mémoires des Savants Étrangers*, 1855, "De la Torsion des Prismes, avec des considérations sur leur Flexion," &c.
² See Thomson and Tait's *Natural Philosophy*, vol. i. § 123.

Venant's conclusions of section 57, shows that, whatever the shape and the distribution of matter in the cross section of the bar, there are two planes at right angles to one another such that if the bar be bent in either of these planes the bending couple will coincide with the plane of flexure. These planes are called principal planes of flexure, and the rigidities of the bar for flexure in these planes are called its principal flexural rigidities. When the principal flexural rigidities are known the flexure of the bar in any plane oblique to the principal planes is readily found by supposing it to be bent in one of the principal planes and simultaneously in the other, and calculating separately the couples required to produce these two component flexures. The positions of the principal planes of flexure, the relative flexural rigidities, and the law of elongation and contraction in different parts of the cross section, are found according to the following simple rules:—

(1.) Imagine an infinitely thin plane disc of the same shape and size as the cross section loaded with matter in simple proportion to the Young's modulus in different parts of the cross section. Let the quantity of matter per unit area on any point of the disc be equal to the Young's modulus on the corresponding point of the rod when the material is heterogeneous: on the other hand, when the material is homogeneous it is more convenient to call the quantity of matter unity per unit area of the disc. Considering different axes in the plane of the disc through its centre of inertia, find the two principal axes of greatest and least moments of inertia, and find the moments of inertia round them.

(2.) In whatever plane the bar be bent it will experience neither elongation nor contraction in the filament which passes through the centres of inertia of the cross sections found according to rule (1), nor in the diameter of the cross section perpendicular to the plane of flexure.

(3.) Thus all the particles which experience neither elongation nor contraction lie in a surface cutting the plane of flexure perpendicularly through the centres of inertia of the cross sections. All the material on the outside of this cylindrical surface is elongated, and all on the interior is contracted, in simple proportion to distance from it: the amount of the elongation or contraction being in fact equal to distance from this neutral surface divided by the radius of its curvature.

(4.) Hence it is obvious that the portions of the solid on the two sides of any cross section must experience mutual normal force, pulling them towards one another in the stretched part, and pressing them from one another in the condensed part, and that the amount of this negative or positive normal pressure per unit of area must be equal to the Young's modulus at the place, multiplied into the ratio of its distance from the neutral line of the cross section to the radius of curvature.

The sum of these positive and negative forces over the whole area of the cross section is zero in virtue of condition (2). Their couple resultant has its axis perpendicular to the plane of curvature when this line is either of the principal axes (3) of the cross section; and its moment is clearly equal to the moment of inertia of the material disc (1) divided by the radius of curvature. Hence the principal flexural rigidities are simply equal to the principal moments of inertia of this disc; and the principal flexural planes are the planes through its principal axes and the length of the bar; or taking the quantity of matter per unit area of the disc unity for the case of a homogeneous bar, we have the rule that the principal rigidities are equal to the product of the Young's modulus into the principal moments of inertia of the cross sectional areas, and the principal planes of flexure are the longitudinal planes through the principal axes of this area.

63. *Law of Torsion.*—One of the most beautiful applications of the general equations of internal equilibrium of an elastic solid hitherto made is that of M. de St Venant to "the torsion of prisms." In this work the mathematical methods invented by Fournier for the solution of problems regarding conduction of heat have been most ingeniously and happily applied by St Venant to the problem of torsion. To reproduce St Venant's mathematical investigation here would make this article too long (it occupies 227 quarto

pages of the *Mémoires des Savants Étrangers*); but a statement of some of the chief results is given (sections 65–72), not only on account of their strong scientific interest, but also because they are of great practical value in engineering; and the reader is referred to Thomson and Tait's *Natural Philosophy*, sections 700–710, for the proofs and for further details regarding results, but much that is valuable and interesting is only to be found in St Venant's original memoir.

64. *Torsion Problem stated and Torsional Rigidity defined.*—To one end of a long, straight prismatic rod, wire, or solid or hollow cylinder of any form, a given couple is applied in a plane perpendicular to the length, while the other end is held fast: it is required to find the degree of twist produced, and the distribution of strain and stress throughout the prism. The moment of the couple divided by the amount of the twist per unit length is called the torsional rigidity of the rod or prism. This definition is founded simply on the extension of Hooke's law to torsion discovered experimentally by Coulomb, according to which a rod or wire when twisted within limits of torsional elasticity exerts a reactive couple in simple proportion to the angle through which one end is turned relatively to the other. The internal conditions to be satisfied in the torsion problem are that the resultant action between the substance on the two sides of any normal section is a couple, in the normal plane, equal to the given couple. This problem has not hitherto been attacked for æolotropic solids. Even such a case as that of the round wooden rod (section 61) with annual layers sensibly parallel to a plane through its length, will, when twisted, experience a distribution of strain complicated much by its æolotropy. The following statements of results are confined to rods of isotropic material.

65. *Torsion of Circular Cylinder.*—For a solid or hollow circular cylinder, the solution (given first, we believe, by Coulomb) obviously is that each circular normal section remains unchanged in its own dimensions, figure, and internal arrangement (so that every straight line of its particles remains a straight line of unchanged length), but is turned round the axis of the cylinder through such an angle as to give a uniform rate of twist equal to the applied couple divided by the product of the moment of inertia of the circular area (whether annular or complete to the centre) into the modulus of rigidity of the substance.

For, if we suppose the distribution of strain thus specified to be actually produced, by whatever application of stress is necessary, we have, in every part of the substance, a simple shear parallel to the normal section, and perpendicular to the radius through it. The elastic reaction against this requires, to balance it (section 43), a simple distorting stress consisting of forces in the normal section, directed as the shear, and others in planes through the axis, and directed parallel to the axis. The amount of the shear is, for parts of the substance at distance r from the axis, equal obviously to τr , if τ be the rate of twist reckoned in radians per unit of length of the cylinder. Hence the amount of the tangential force in either set of planes is $n\tau$ per unit of area, if n be the rigidity of the substance. Hence there is no force between parts of the substance lying on the two sides of any element of any circular cylinder coaxial with the bounding cylinder or cylinders; and consequently no force is required on the cylindrical boundary to maintain the supposed state of strain. And the mutual action between the parts of the substance on the two sides of any normal plane section consists of force in this plane, directed perpendicular to the radius through each point, and amounting to $n\tau r$ per unit of area. The moment of this distribution of force round the axis of the cylinder is (if $d\sigma$ denote an element of the area) $n\tau r^2 d\sigma$, or the

product of πr into the moment of inertia of the area round the perpendicular to its plane through its centre, which is therefore equal to the moment of the couple applied at either end.

66. *Prism of any shape constrained to a Simple Twist.*—Farther, it is easily proved that if a cylinder or prism of any shape be compelled to take exactly the state of strain above specified (section 65) with the line through the centres of inertia of the normal sections, taken instead of the axis of the cylinder, the mutual action between the parts of it on the two sides of any normal section will be a couple of which the moment will be expressed by the same formula, that is, the product of the rigidity, into the rate of twist, into the moment of inertia of the section round its centre of inertia. But for any other shape of prism than a solid or symmetrical hollow circular cylinder, the supposed state of strain requires, besides the terminal opposed couples, force parallel to the length of the prism, distributed over the prismatic boundary, in proportion to the distance PE along the tangent, from each point of the surface, to the point in which this line is cut by a perpendicular to it from O the centre of inertia of the normal section. To prove this let a normal section of the prism be represented in the annexed diagram (fig. 6). Let PK, representing the shear at any point P, close to the prismatic boundary, be resolved into PN and PT along the normal and tangent respectively. The whole, shear PK being equal to τr its component PN is equal to $\tau r \sin \omega$ or $\tau \cdot PE$. The corresponding component of the required stress is $\pi r \cdot PE$, and involves equal forces in the plane of the diagram, and in the plane through TP perpendicular to it, each amounting to $\pi r \cdot PE$ per unit of area.

Fig 6.

An application of force equal and opposite to the distribution thus found over the prismatic boundary, would of course alone produce in the prism, otherwise free, a state of strain which, compounded with that supposed above, would give the state of strain actually produced by the sole application of balancing couples to the two ends. The result, it is easily seen, consists of an increased twist, together with a warping of naturally plane normal sections, by infinitesimal displacements perpendicular to themselves, into certain surfaces of antilastic curvature, with equal opposite curvatures. In bringing forward this theory, St Venant not only pointed out the falsity of the supposition admitted by several previous writers, and used in practice fallaciously by engineers, that Coulomb's law holds for other forms of prism than the solid or hollow circular cylinder, but he discovered fully the nature of the requisite correction, reduced the determination of it to a problem of pure mathematics, worked out the solution for a great variety of important and curious cases, compared the results with observation in a manner satisfactory and interesting to the naturalist, and gave conclusions of great value to the practical engineer.

67. *"Hydrokinetic Analogue to Torsion Problem."*—We take advantage of the identity of mathematical conditions in St Venant's torsion problem, and a hydrokinetic problem first solved a few years earlier by Stokes,² to give the following statement, which will be found very useful in estimating deficiencies in torsional rigidity below the amount calculated from the fallacious extension of Coulomb's law:—

"Conceive a liquid of density π completely filling a closed infinitely light prismatic box of the same shape within as the given elastic prism and of length unity, and let a couple be applied to the box in a plane perpendicular to its length. The effective moment of inertia of the liquid³ will be equal to the correction by which the torsional rigidity of the elastic prism, calculated by the false extension of Coulomb's law, must be diminished to give the true torsional rigidity.

"Farther, the actual shear of the solid, in any infinitely thin plate of it between two normal sections, will at each point be, when reckoned as a differential sliding (section 45) parallel to their planes, equal to and in the same direction as the velocity of the liquid relatively to the containing box."

68. *Solution of Torsion Problem.*—To prove these propositions and investigate the mathematical equations of the problem, the process followed in Thomson and Tait's *Natural Philosophy*, section 706, is first to show that the conditions of sections 63 are verified by a state of strain compounded of (1) a simple twist round the line through the centres of inertia, and (2) a distortion of each normal section by infinitesimal displacements perpendicular to its plane; then find the interior and surface equations to determine this warping; and lastly, calculate the actual moment of the couple to which the mutual action between the matter on the two sides of any normal section is equivalent.

69. St Venant's treatise abounds in beautiful and instructive graphical illustrations of his results, from which the following are selected:—

(1.) *Elliptic Cylinder.*—The plain and dotted curvilinear arcs are (fig. 7) "contour lines" (*coupes topographiques*) of the section as warped by torsion; that is to say, lines in which it is cut by a series of parallel planes, each perpendicular to the axis. The arrows indicate the direction of rotation in the part of the prism above the plane of the diagram.

Fig. 7.

Fig. 8.

¹ Extracted from Thomson and Tait, sections 704, 705
² "On some cases of Fluid Motion."—Camb. Phil. Trans., 1845

³ "That is, the moment of inertia of the liquid, calculated by the false extension of Coulomb's law, must be diminished to give the true torsional rigidity."

(2.) *Contour lines for St Venant's "étoile à quatre points arrondis."*—This diagram (fig. 8) shows the contour lines, in all respects as in case (1), for the case of a prism having for section the figure indicated. The portions of curve outside the continuous closed curve are merely indications of mathematical extensions irrelevant to the physical problem.

(3.) *Contour lines of normal section of triangular prism, as warped by torsion,* shown as in case (1) (fig. 9).

Fig. 9.

(4.) *Contour lines of normal sections of square prisms as warped by torsion* (fig. 10).

Fig. 10

(5.) *Diagram of St Venant's curvilinear squares for which torsion problem is algebraically solvable.*—This diagram (fig. 11) shows the series of lines represented by the equation $x^2 + y^2 - a(x^4 - 6x^2y^2 + y^4) = 1 - a$, with the indicated values for a . It is remarkable that the values $a = 0.5$ and $a = -\frac{1}{2}(\sqrt{2} - 1)$ give similar but not equal curvilinear squares (hollow sides and acute angles), one of them turned through half a right angle relatively to the other.

70. *Torsional Rigidity less in proportion to sum of principal Flexural Rigidities than according to false extension* (section 66) of Coulomb's Law.—Inasmuch as the moment of inertia of a plane area about an axis through its centre of inertia perpendicular to its plane is obviously equal to the sum of its moments of inertia round any two axes through the same point at right angles to one another in its plane, the fallacious extension of Coulomb's law, referred to in section 66, would make the torsional rigidity of a bar of any section equal to the product of the ratio of the modulus of rigidity to the Young's modulus into the sum of its flexural rigidities (section 61) in any two planes at right angles to one another through its length. The true theory, as we have seen (section 67), always gives a torsional rigidity less than this. How great the deficiency

may be expected to be in cases in which the figure of the section presents projecting angles, or considerable prominences (which may be imagined from the hydrokinetic

Fig. 11

analogy given in section 67), has been pointed out by M. de St Venant, with the important practical application, that strengthening ribs, or projections (see, for instance, the second of the annexed diagrams), such as are introduced in engineering to give stiffness to beams, have the reverse of a good effect when torsional rigidity or strength is an object, although they are truly of great value in increasing the flexural rigidity, and giving strength to bear ordinary strains, which are always more or less flexural. With remarkable ingenuity and mathematical skill he has drawn beautiful illustrations of this important practical principle from his algebraic and transcendental solutions.

Fig. 12.—Diagrams showing torsional rigidities

Thus, for an equilateral triangle, and for the rectilinear and three curvilinear squares shown in the diagrams (fig 12), he finds for the torsional rigidities the values stated. The number immediately below the diagram indicates in each case the fraction which the true torsional rigidity is of the old fallacious estimate (section 66),—the latter being the product of the rigidity of the substance into the moment of inertia of the cross section round an axis perpendicular to its plane through its centre of inertia. The second number indicates in each case the fraction which the torsional rigidity is of that of a solid circular cylinder of the same sectional area.

71. *Places of greatest Distortion in Twisted Prisms.*—M. de St Venant also calls attention to a conclusion from his solutions which to many may be startling, that in his simpler cases the places of greatest distortion are those points of the boundary which are nearest to the axis of the twisted prism in each case, and the places of least distortion those farthest from it. Thus in the elliptic cylinder the

substance is most strained at the ends of the smaller principal diameter, and least at the ends of the greater. In the equilateral triangular and square prisms there are longitudinal lines of maximum strain through the middles of the sides. In the oblong rectangular prism there are two lines of greater maximum strain through the middles of the broader pair of sides, and two lines of less maximum strain through the middles of the narrow sides. The strain is, as we may judge from the hydrokinetic analogy, excessively small, but not evanescent, in the projecting ribs of a prism of the figure shown in (2) of section 69. It is quite evanescent infinitely near the angle, in the triangular and rectangular prisms, and in each other case, as (5) of section 69, in which there is a finite angle, whether acute or obtuse, projecting outwards. This reminds us of a general remark we have to make, although consideration of space may oblige us to leave it without formal proof.

72. *Strain at Projecting Angles, evanescent; at Re-entrant Angles, infinite, Liability to Cracks proceeding from Re-entrant Angles, or any places of too sharp concave curvature.*—A solid of any elastic substance, isotropic or æolotropic, bounded by any surfaces presenting projecting edges or angles, or re-entrant angles or edges, however obtuse, cannot experience any finite stress or strain in the neighbourhood of a projecting angle (triangular, polyhedral, or conical); in the neighbourhood of an edge, can only experience simple longitudinal stress parallel to the neighbouring part of the edge; and generally experiences infinite stress and strain in the neighbourhood of a re-entrant edge or angle: when influenced by any distribution of force, exclusive of surface tractions infinitely near the angles or edges in question. An important application of the last part of this statement is the practical rule, well known in mechanics, that every re-entering edge or angle ought to be rounded, to prevent risk of rupture, in solid pieces designed to bear stress. An illustration of these principles is afforded by the concluding example of torsion in Thomson and Tait's section 707; in which we have the complete mathematical solution of the torsion problem for prisms of fan-shaped sections, such as the annexed forms (fig. 13).

Fig. 13.

The solution shows that when the solid is continuous from the circular cylindrical surface to its axis, as in (4), (5), (6), the strain is zero or infinite according as the angle between the bounding planes of the solid is less than or greater than two right angles as in cases (4) and (6) respectively.

73. *Changes of Temperature produced by Compressions or Dilatations of a Fluid and Stresses of any kind in an Elastic Solid.*—From thermodynamic theory¹ it is concluded that cold is produced whenever a solid is strained by opposing, and heat when it is strained by yielding to, any elastic force of its own, the strength of which would diminish if the temperature were raised; but that, on the contrary, heat is produced when a solid is strained against, and cold when it is strained by yielding to, any elastic force of its own, the strength of which would increase if the temperature were raised. When the strain is a condensation or dilatation, uniform in all directions, a fluid may be

included in the statement. Hence the following propositions:—

(1.) A cubical compression of any elastic fluid or solid in an ordinary condition causes an evolution of heat; but, on the contrary, a cubical compression produces cold in any substance, solid or fluid, in such an abnormal state that it would contract if heated while kept under constant pressure. Water below its temperature ($3^{\circ}9$ Cent.) of maximum density is a familiar instance. (See table of section 76.)

(2.) If a wire already twisted be suddenly twisted further, always, however, within its limits of elasticity, cold will be produced; and if it be allowed suddenly to untwist, heat will be evolved from itself (besides heat generated externally by any work allowed to be wasted, which it does in untwisting). It is assumed that the torsional rigidity of the wire is diminished by an elevation of temperature, as the writer of this article had found it to be for copper, iron, platinum, and other metals (compare section 78).

(3.) A spiral spring suddenly drawn out will become lower in temperature, and will rise in temperature when suddenly allowed to draw in. [This result has been experimentally verified by Joule ("Thermodynamic Properties of Solids," *Trans. Roy. Soc.*, 1858) and the amount of the effect found to agree with that calculated, according to the preceding thermodynamic theory, from the amount of the weakening of the spring which he found by experiment.]

(4.) A bar or rod or wire of any substance with or without a weight hung on it, or experiencing any degree of end thrust, to begin with, becomes cooled if suddenly elongated by end pull or by diminution of end thrust, and warmed if suddenly shortened by end thrust or by diminution of end pull; except abnormal cases in which with constant end pull or end thrust elevation of temperature produces shortening; in every such case pull or diminished thrust produces elevation of temperature, thrust or diminished pull lowering of temperature.

(5.) An india-rubber band suddenly drawn out (within its limits of elasticity) becomes warmer; and when allowed to contract, it becomes colder. Any one may easily verify this curious property by placing an india-rubber band in slight contact with the edges of the lips, then suddenly extending it—it becomes very perceptibly warmer: hold it for some time stretched nearly to breaking, and then suddenly allow it to shrink—it becomes quite startlingly colder, the cooling effect being sensible not merely to the lips but to the fingers holding the band. The first published statement of this curious observation is due to Gough (*Memoirs of the Literary and Philosophical Society of Manchester*, 2d series, vol. i. p. 288), quoted by Joule in his paper on "Thermodynamic Properties of Solids" (*Transactions of Royal Society*, 1858). The thermodynamic conclusion from it is that an india-rubber band, stretched by a constant weight of sufficient amount hung on it, must, when heated, pull up the weight, and, when cooled, allow the weight to descend: this Gough, independently of thermodynamic theory, had found to be actually the case. The experiment any one can make with the greatest ease by hanging a few pounds weight on a common india-rubber band, and taking a red-hot coal in a pair of tongs, or a red-hot poker, and moving it up and down close to the band. The way in which the weight rises when the red-hot body is near, and falls when it is removed, is quite startling. Joule experimented on the amount of shrinking per degree of elevation of temperature, with different weights hung on a band of vulcanized india-rubber, and found that they closely agreed with the amounts calculated by Thomson's theory from the heating effects of pull, and cooling effects of ceasing to pull, which he had observed in the same piece of india-rubber.

¹ W. Thomson on "Thermo-elastic Properties of Matter," in *Quarterly Journal of Mathematics*, April 1855 (republished in *Phil. Mag.* 1877, second half year.)

$$\frac{p}{M} - c \frac{tep}{JK\rho}.$$

Dividing p by this expression we find for the kinetic modulus

$$M' = \frac{1}{1 - \frac{te^2}{JK\rho}}$$

Hence

$$\frac{M'}{M} = \frac{1}{1 - \frac{te^2 M}{JK\rho}}.$$

76. For any substance, fluid or solid, it is easily proved, without thermodynamic theory, that

$$\frac{M'}{M} = \frac{K}{N};$$

where K denotes the thermal capacity of a stated quantity of the substance under constant stress, and N its thermal capacity under constant strain (or thermal capacity when the body is prevented from change of shape or change of volume). For permanent gases, and generally for fluids approximately fulfilling Boyle's and Charles's laws as said above, k is proved by thermodynamic theory to be approximately constant. Its value for all gases for which it has been measured differs largely from unity, and probably also for liquids generally (except water near its temperature of maximum density).

On the other hand, for solids whether the stress considered be uniform compression in all directions or of any other type, the value of $\frac{M'}{M}$ or $\frac{K}{N}$ differs but very little from unity; and both for solids and liquids it is far from constant at different temperatures (in the case of water it is zero at 3°·9 Cent., and varies as the square of the difference of the temperature from 3°·9 at all events for moderate differences from this critical temperature, whether above or below it). The following tables show the value of $\frac{M'}{M}$ or $\frac{K}{N}$, and the value of θ by the formula of sec. 74, for different fluid and solid substances at the temperature 15° Cent. (289° absolute scale). The first table is for compression uniform in all directions; the second, necessarily confined to solids, is for the stress dealt with in "Young's Modulus," that is, normal pressure (positive or negative) on one set of parallel planes, with perfect freedom to expand or contract in all directions in these planes. A wire or rod pulled longitudinally is a practical application of the latter.

77. *Experimental Results.*—The following tables show determinations of modulus of compression, of Young's modulus, and of modulus of rigidity by various experimenters and various methods. It will be seen that the Young's modulus obtained by Wertheim by vibrations, longitudinal or transverse, are generally in excess of those which he found by static extension; but the differences are enormously greater than those due to the heating and cooling effects of elongation and contraction (section 76), and are to be certainly reckoned as errors of observation. It is probable that his modulus determined by static elongation are minutely accurate; the discrepancies of those found by vibrations are probably due to imperfections of the arrangements for carrying out the vibrational method:—

78. A question of great importance in the physical theory of the elasticity of solids, "What changes are produced in the modulus of elasticity by permanent changes in its molecular condition," has occupied the attention, no doubt, of every "naturalist" who has studied the subject, and valuable contributions to its answer by experiment had been given by Wertheim and other investigators, but solely with reference to Young's modulus. In 1865 an investigation of the effect on the torsional rigidity of wires of different metals, produced by stretching them longitudinally beyond their limits of elasticity, was commenced in the physical laboratory of the university of Glasgow in its old buildings in 1865. The following description of experiments and table of results is extracted from the paper by W. Thomson "On the Elasticity and Viscosity of Metals," already quoted (section 30), with reference to viscosity and fatigue of elasticity.

"To determine rigidities by torsional vibrations, taking advantage of an obvious but most valuable suggestion made to me by Dr Joule, I used as vibrator in each case a thin cylinder of sheet brass, turned true outside and inside (of which the radius of gravitation must be, to a very close degree of approximation, the arithmetic mean of the radii of the outer and inner cylindrical surfaces),¹ supported by a thin flat rectangular bar, of which the square of the radius of gravitation is one-third of the square of the distance from the centre to the corner. The wire to be tested passed perpendicularly through a hole in the middle of the bar, and was there firmly soldered. The cylinder was tied to the middle of the bar by light silk thread so as to hang with its axis vertical. Each wire, after having been suspended and stretched with just force enough to make it as nearly straight as was necessary for accuracy, was vibrated. Then it was stretched by hand (applied to the cross bar soldered to its lower end) and vibrated again, and stretched again, and so on till it broke." The experiments were performed with great care and accuracy by Mr Donald McFarlane. "The results, as shown in the accompanying table, were most surprising."

The highest and lowest rigidities found for copper in the table are as follows:—

Highest rigidity 473×10^6 , being that of a wire which had been softened by heating it to redness and plunging it into water, and which was found to be of density 8.91.

Lowest rigidity $393 \frac{1}{2} \times 10^6$, being that of a wire which had been rendered so brittle by heating it to redness surrounded by powdered charcoal in a crucible and letting it cool very slowly, that it could scarcely be touched without breaking it, and which had been found to be reduced in density by this process to as low as 8.674. The wires used were all commercial specimens—those of copper being all, or nearly all, cut from bunks supplied by the Gutta Percha Company, having been selected as of high electric conductivity, and of good mechanical quality, for submarine cables.

It ought to be remarked that the change of molecular condition produced by permanently stretching a wire or solid cylinder of metal is certainly a change from a condition which, if originally isotropic, becomes anisotropic as to some qualities,² and that the changed conditions may therefore be presumed to be anisotropic as to elasticity. If so, the rigidities corresponding to the direct and diagonal distortions (indicated by No. 1 and No. 2 in fig. 14) must in all probability become different from one another when a wire is permanently stretched, instead of being equal as they must be when its substance is isotropic. It becomes, therefore, a question of extreme interest to find whether rigidity No. 2 is not increased by this process, which, as is proved by the experiments above described, diminishes, to a very remarkable degree, the rigidity No. 1. The most obvious experiment, and indeed the only practicable experiment, adapted to answer this question, for a wire or round bar is that of Cagniard-Latour, in which an accurate determination of the difference produced in the volume of the substance is made by applying and removing longitudinal traction within its limits of elasticity. With the requisite apparatus, which must be much more accurate

Fig. 14.

than that of Cagniard-Latour, a most important and interesting investigation might be made. The results, along with an accurate determination of the Young's modulus for the particular case, give (see. 47) the modulus of compression, and the rigidity No. 2. Regnault suggested the use of hollow instead of solid cylinders, to be subjected to longitudinal pull, and (after the manner of the bulb and tube of a thermometer) a capillary tube to aid in measuring changes of volume of the hollow; and Wertheim, adopting this excellent suggestion, obtained seemingly very accurate results for brass and glass, which are given in the tables of section 77.

Substance.	Length of Wire in centimetres.	Volume in cubic centimetres.	Density.	Moment of Inertia of Vibrator Wk^2	Time of Vibration one way or (half period) in seconds. T.	Rigidity in grammes weight per square centimetre $\frac{2\pi^2 Wk^2}{9T^2 V}$.

Remarks.

¹ Only forty vibrations from initial arc of convenient amplitude could be counted. Had been stretched considerably before this experiment.

² So viscous that only twenty vibrations could be counted. Broke in stretching.

³ A piece of the preceding stretched.

⁴ The preceding made red-hot in a crucible filled with powdered charcoal and allowed to cool slowly, became very brittle: a part of it with difficulty saved for the experiment.

⁵ Another piece of the long (2135 centims.) wire; stretched by successive simple tractions.

⁶ A finer gauge copper wire; stretched by successive tractions.

⁷ A finer gauge copper wire, softened by being heated to redness and plunged in water. A length of 260 centimetres cut from this, and elongated by successive tractions.

⁸ Another length of 260 centimetres cut from the same, and similarly treated.

⁹ One piece, successively elongated by simple tractions till it broke.

¹ It is exactly the square root of the mean of their squares.
² For example, see paper "On Electrodynamical Qualities of Metals," 1856 by W. Thomson.

79. The following tables show the effects of differences of temperature on the Young's Modulus, rigidity-modulus, and modulus of compressibility of various substances:—

Substance.	Density	Young's Modulus in million grms. per square centimetre.		
		15°	100°	200°
Lead	11 232	173	163	
Gold	18 036	558	531	548
Silver	10 304	715	727	637
Palladium	11 225	979		
Copper	8 936	1052	938	786
Platinum	21 083	1552	1418	1296
Steel, drawn, English..	7 622	1728	2129	1928
Cast steel	7 919	1956	1901	1792
Iron, Berry	7 757	2079	2188	1770

The above results are from Wertheim's "Mémoires" on Elasticity, *Ann. de Chim. et Phys.*, tom xii. (1844).

The change in the rigidity-modulus produced by change of temperature was investigated by Kohlrausch. He found that it is expressed by the formula $n = n_0 (1 - \alpha t - \beta t^2)$, where n_0 denotes the value of the rigidity-modulus at 0° C., n its value at temperature t , and α , β coefficients the values of which for iron, copper, and brass are as follows:—

	α	β
Iron	0 000447	0 00000052
Copper..	0 000520	0 00000028
Brass.	0 000428	0 00000136

80. *Tempering soft iron by long-continued stress.*—Preliminary experiments by Mr J. T. Bottomley towards the investigation promised in section 5 above have discovered a very remarkable property of soft iron wire, respecting its ultimate tensile strength. Eight different specimens, tested by the gradual application of more and more weight within ten minutes of time in each case until the wire broke, bore from 43½ to 46 lb (average 45 2) just before breaking with elongations of from 17 per cent to 22 per cent. Another specimen left with 43 lb hanging on it for 24 hours, and then tested by the gradual addition of weights during 25 minutes till it broke, bore 49½ lb before breaking, with elongation of 15 per cent. Another left for 3 days 11 hours 40 minutes with 43 lb hanging on it, and then tested by the gradual addition of weights during 34 minutes till it broke, bore 51½ lb just before breaking, with elongation of 14 4 per cent. Another specimen of the same wire was set up with 40 lb hanging on it on the 5th of July 1877, on the 6th of July 3 lb were added, on the 9th 1½ lb more, and on the 10th ¾ lb more, making in all on this date 45½ lb. Thenceforward day by day, with occasional intervals of two days or three days, the weight

¹ The modulus seems to be a minimum near the temperature of maximum density

was increased first by half a pound at a time, and latterly by a quarter of a pound at a time, until on the 3d of September the wire broke with 57½ lb (elongation not recorded). This gradual addition of weight therefore had increased the tensile strength of the metal by 26 7 per cent.!

81. *Experiments made for this article.*—There are many subjects in the theory of elasticity regarding which information to be obtained by experiment only is greatly wanted. Several of these have been pointed out above (section 21), and while this article was being put in type, experiments were made in the physical laboratory of the university of Glasgow with a view of answering some of the questions proposed. Mr Donald M'Farlane, besides making the experiments referred to in sections 3 and 21, investigated the effects of applying different amounts of pull to a steel pianoforte wire which had been twisted to nearly its limits of elasticity, and which was kept twisted by means of a couple. The results proved a deviation from Hooke's law by showing a diminution of the torsional rigidity, of about 1 6 per cent, produced by hanging a weight of 112 lb on the wire. Of this 1 2 per cent. is accounted for by elongation and by shrinkage of the diameter, leaving 4 per cent. of diminution of the rigidity-modulus.

It was also found that when the wire was twisted far beyond its limits of elasticity, and then freed from torsional stress, a weight hung on it caused it to untwist slightly. When the weight was removed and reapplied again and again, the lower end of the wire always turned in the same direction as the permanent twist when the weight was removed, and in the opposite direction when it was applied. This result shows the development of æolotropic quality in the substance of the wire, according to which a small cube cut from any part of it far out from the axis, with two sides of the cube parallel to the length, and the other two pairs of sides making angles of 45° with the length, would show different compressibilities in the directions perpendicular to the last-mentioned pairs of sides.

Another very interesting result, discovered in the course of these experiments, was that when a length of five metres of the steel wire, with a weight of 39 lb hung upon it, was twisted to the extent of 95 turns, it became gradually elongated to the extent of $\frac{1}{1000}$ of the length of the wire; when farther twisted it began to shorten till, when 25 turns had been given (in all 120 turns), the weight had risen from its lowest position through nearly $\frac{1}{1000}$ of the length of the wire, so that the previous elongation had been diminished by about $\frac{1}{4}$ of its amount.

Experiments were also made by Mr Andrew Gray and Mr Thomas Gray for the purpose of determining the effects of various amounts of permanent twist in altering the rigidity-modulus and the Young's modulus of wires of copper, iron, and steel. A copper wire, of 3 15 metres in length and 154 centimetre diameter, No. 17 B.W.G., which had a rigidity-modulus of 442 million grammes per square centimetre to begin with, was found to have 420 after 10 turns, showing a diminution in the modulus of $\frac{1}{10}$ of its own amount. The diminution went on rapidly until 100 turns of permanent twist had been given, when the modulus was as low as 385. The diminution of the modulus continued with further twist, but very slowly, up to 1225 turns, when the modulus was found to be 371, showing a diminution to the extent of $\frac{1}{4}$ of its original value! There was little farther change until 1400 turns had been given, when the modulus began to increase. At 1525 turns its value was 373, and at 1625 it was 377. Twenty turns more broke the wire before the torsional elasticity had been again determined.

A piece of iron wire of nearly the same length, about three metres, but of smaller diameter (0 87 centimetre), showed continued diminution of torsional rigidity as far as

1350 turns of permanent twist, when the diminution had amounted to 14 per cent. of the primitive value, 36 turns more broke the wire before another determination of torsional rigidity had been made.

The steel pianoforte wire also showed a diminution of torsional rigidity with permanent twist, and (as did the copper wire) showed first a diminution and then a slight augmentation. The amount of the diminution in the steel wire was enormously greater than the surprisingly great amount which had been discovered in the copper wire, and the ultimate augmentation was considerably greater in the steel than what it had been in the copper before rupture. Thus after 473 turns of permanent twist the torsional modulus had diminished from 751 million grammes per square centimetre to 414! 95 more turns of permanent twist augmented the rigidity from 414 to 430, and when farther twisted the wire broke before another observation had been made. The vibrator used in these experiments was a cylinder of lead weighing 56 lb, which was kept hanging on the wire while it was being twisted, and in fact during the whole of about 100 hours from the beginning of the experiment till the wire broke, except on two occasions for a few minutes, while the top fastening which had given way was being resoldered. The period of vibration was augmented from 39.375 seconds to 51.9 seconds by the twist. The wire took the twist very irregularly, some parts not beginning to show much signs of permanent twist till near the end of the experiment.

In two specimens of copper wire of the same length and gauge as those described above, the Young's modulus was found to be increased 10 per cent. by 100 turns of permanent twist.

Five metres of the steel pianoforte wire, bearing a weight of 39 lb, was in one of Mr M'Farlane's experiments twisted 120 turns, and then allowed to untwist, and 38½ turns came out, leaving the wire in equilibrium with 81½ turns of permanent twist. Its Young's modulus was then found not to differ as much as ½ per cent. from the value it had before the wire was twisted.

MATHEMATICAL THEORY OF ELASTICITY.¹

PART I.—ON STRESSES AND STRAINS.²

CHAPTER I.—Initial Definitions and Explanations.

Def. A stress is an equilibrating application of force to a body.

Cor. The stress on any part of a body in equilibrium will thus signify the force which it experiences from the matter touching that part all round, whether entirely homogeneous with itself, or only so across a portion of its bounding surface.

Def. A strain is any definite alteration of form or dimensions experienced by a solid.

Examples.—Equal and opposite forces acting at the two ends of a wire or rod of any substance constitute a stress upon it. A body pressed equally all round of any substance constitute a stress upon it. A body pressed equally all round of any substance touched by air on all sides—experiences a stress. A stone in a building experiences stress if it is pressed upon by other stones, or by any parts of the structure, in contact with it. Any part of a continuous solid mass, simply resting on a fixed base, experiences stress from the surrounding mass, in consequence of their weight. The different parts of a ship in a heavy sea experience stresses from which they are exempt when the water is smooth. If a rod of any substance become either longer or shorter, it is said to experience a strain. If a body be uniformly condensed in all directions it experiences a strain. If a stone, a beam, or a mass of metal in a building, or in a piece of framework, becomes condensed or dilated in any direction, or bent, or twisted, or distorted in any way, it is said to experience a strain, to become strained, or in often in common language, simply "to strain." A ship is said to "strain" if in launching, or when working in a heavy sea, the different parts of it experience relative motions.

CHAPTER II.—Homogeneous Stresses and Homogeneous Strains.

Def. A stress is said to be homogeneous throughout a body when equal and similar portions of the body, with corresponding lines

parallel, experience equal and parallel pressures or tensions on corresponding elements of their surfaces.

Cor. When a body is subjected to any homogeneous stress, the mutual tension or pressure between the parts of it on two sides of any plane amounts to the same per unit of surface as that between the parts on the two sides of any parallel plane, and the former tension or pressure is parallel to the latter.

A strain is said to be homogeneous throughout a body, or the body is said to be homogeneously strained, when equal and similar portions, with corresponding lines parallel, experience equal and similar alterations of dimensions.

Cor. All the particles of the body in parallel planes remain in parallel planes, when the body is homogeneously strained in any way.

Examples.—A long uniform rod, if pulled out, or a pillar loaded with a weight, will experience a uniform strain, except near its ends. There will be a sensible heterogeneity of the strain, because of the end attachments, or other circumstances preventing the ends from expanding laterally to the same extent as the middle does.

A piece of cloth held in a plane, and distorted so that a warp and woof, instead of being perpendicular to one another, become two sets of parallels cutting one another obliquely, experiences a homogeneous strain. The strain is heterogeneous as to intensity, from the axis to the surface of a cylindrical wire under torsion, and heterogeneous as to direction in different positions in a circle round the axis.

CHAPTER III.—On the Distribution of Force in a Stress

Theorem.—In every homogeneous stress there is a system of three rectangular planes, each of which is perpendicular to the direction of the mutual force between the parts of the body on its two sides.

For let $P(X)$, $P(Y)$, $P(Z)$ denote the components, parallel to X , Y , Z , any three rectangular lines of reference, of the force experienced per unit of surface at any portion of the solid bounded by a plane parallel to (Y, Z) ; $Q(X)$, $Q(Y)$, $Q(Z)$, the corresponding components of the force experienced by any surface of the solid parallel to (Z, X) , and $R(X)$, $R(Y)$, $R(Z)$, those of the force at a surface parallel to (X, Y) . Now, by considering the equilibrium of a cube of the solid with faces parallel to the planes of reference (fig 15), we see that the couple of forces $Q(Z)$ on its two faces perpendicular to Y is balanced by the couple of forces $R(Y)$ on the faces perpendicular to Z . Hence we must have

$$Q(Z) = R(Y)$$

Similarly it is seen that

$$R(X) = P(Z)$$

and

$$P(Y) = Q(X)$$

For the sake of brevity, these pairs of equal quantities (being mutual forces respectively perpendicular to X , Y , Z) may be denoted by $T(X)$, $T(Y)$, $T(Z)$.

Consider a tetrahedral portion of the body (surrounded it may be with continuous solid) contained within three planes A , B , C , through a point O parallel to the planes of the pairs of lines of reference, and a third plane K cutting these at angles α , β , γ respectively; so that as regards the areas of the different sides we shall have

$$A = K \cos \alpha, \quad B = K \cos \beta, \quad C = K \cos \gamma.$$

The forces actually experienced by the sides A , B , C have nothing to balance them except the force actually experienced by K . Hence those three forces must have a single resultant, and the force on K must be equal and opposite to it. If, therefore, the force on K per unit of surface be denoted by F , and its direction cosines by l , m , n , we have

$$FK \cdot l = P(X)A + T(Z)B + T(Y)C,$$

$$FK \cdot m = T(Z)A + Q(Y)B + T(X)C,$$

$$FK \cdot n = T(Y)A + T(X)B + R(Z)C,$$

and, by the relations between the cases stated above, we deduce

$$Fl = P(X) \cos \alpha + T(Z) \cos \beta + T(Y) \cos \gamma$$

$$Fm = T(Z) \cos \alpha + Q(Y) \cos \beta + T(X) \cos \gamma$$

$$Fn = T(Y) \cos \alpha + T(X) \cos \beta + R(Z) \cos \gamma$$

Hence the problem of finding (α, β, γ) , so that the force F (l, m, n) may be perpendicular to it, will be solved by substituting $\cos \alpha$, $\cos \beta$, $\cos \gamma$ for l, m, n in these equations. By the elimination of $\cos \alpha$, $\cos \beta$, $\cos \gamma$ from the three equations thus obtained, we have the well-known cubic determinantal equation, of which the roots, necessarily real, lead, when no two of them are equal, to one and only one system of three rectangular axes having the stated property.

¹ The substance of Chap. I.-XVI of this part of the present article was read before the Royal Society by Prof Wm Thomson, M.A., F.R.S., April 24, 1856, and published in the *Transactions* Chap. XVII, containing the mathematical theory of Waves in an anisotropic or isotropic elastic solid, is new.

² These terms were first definitively introduced into the Theory of Elasticity by Rankine, and have been found very valuable in writing on the subject. It will be seen that there is a slight deviation from Rankine's definition of the word "stress." It is here applied to the direct action experienced by a body from the matter around it, and not, as proposed by him, to the elastic reaction of the body equal and opposite to that action.

Def. The three lines thus proved to exist for every possible homogeneous stress are called its axes. The planes of their pairs are called its normal planes, the mutual forces between parts of the body separated by these planes, or the forces on portions of the bounding surface parallel to them, are called the principal tensions.

Cor. 1 The Principal Tensions of the stress are the roots of the determinant cubic referred to in the demonstration.

Cor. 2 If a stress be specified by the notation $P(X)$, &c., as explained above, its normal planes are the principal planes of the surface of the second degree whose equation is

$$P(X)X^2 + Q(Y)Y^2 + R(Z)Z^2 + 2T(X)YZ + 2T(Y)ZX$$

and its principal tensions are equal to the reciprocals of the squares of the lengths of the semi-principal-axes of the same surface (quantities which are negative of course for the principal axis or axes which do not cut the surface when the surface is a hyperboloid of one or two sheets)

Cor. 3 The ellipsoid whose equation, referred to the rectangular axes of a stress, is

$$(1 - 2eF)X^2 + (1 - 2eG)Y^2 + (1 - 2eH)Z^2 = 1,$$

where F, G, H denote the principal tensions, and e any infinitely small quantity, represents the stress, in the following manner —

From any point P in the surface of the ellipsoid draw a line in the tangent plane half-way to the point where this plane is cut by a perpendicular to it through the centre; and from the end of the first-mentioned line draw a radial line to meet the surface of a sphere of unit radius concentric with the ellipsoid. The tension at this point of the surface of a sphere of the solid is in the line from it to the point P , and its amount per unit of surface is equal to the length of that infinitely small line, divided by e .

Cor. 4 Any stress is fully specified by six quantities, viz., its three principal tensions (F, G, H), and three angles (θ, ϕ, ψ) or three numerical quantities equivalent to the nine direction cosines specifying its axes

CHAPTER IV — On the Distribution of Displacement in a Strain

Prop. In every homogeneous strain any part of the solid bounded by an ellipsoid remains bounded by an ellipsoid

For all particles of the solid in a plane remain in a plane, and two parallel planes remain parallel. Consequently every system of conjugate diametral planes of an ellipsoid of the solid retain the property of conjugate diametral planes with reference to the altered curve surface containing the same particles. This altered surface is therefore an ellipsoid

Prop. There is a single system (and only a single system, except in the cases of symmetry) of three rectangular planes for every homogeneous strain, which remain at right angles to one another in the altered solid.

Def. 1. These three planes are called the normal planes of the strain, or simply the strain-normals. Their lines of intersection are called the axes of the strain. The elongations of the solid per unit of length along these axes or perpendicular to these planes are called the Principal Elongations of the strain.

Remark. The preceding propositions and definitions are not limited to infinitely small strains, but are applicable to whatever extent the body may be strained.

Prop. If a body, while experiencing an infinitely small strain, be held with one point fixed and the normal planes of the strain parallel to three fixed rectangular planes through the point O , a sphere of the solid of unit radius having this point for its centre becomes, when strained, an ellipsoid, whose equation, referred to the strain-normals through O , is

$$(1 - 2x)X^2 + (1 - 2y)Y^2 + (1 - 2z)Z^2 = 1,$$

if x, y, z denote the elongations of the solid per unit of length, in the directions respectively perpendicular to these three planes, and the position, on the surface of this ellipsoid, attained by any particular point of the solid, is such that if a line be drawn in the tangent plane, half-way to the point of intersection of this plane with a perpendicular from the centre, a radial line drawn through its extremity cuts the primitive spherical surface in the primitive position of that point.

Cor. 1. For every stress, there is a certain infinitely small strain, and conversely, for every infinitely small strain, there is a certain stress, so related that if, while the strain is being acquired, the centre and the strain-normals through it are unmoved, the absolute displacements of particles belonging to a spherical surface of the solid represent, in intensity (according to a definite convention as to units for the representation of force by lines) and in direction, the force (reckoned as to intensity, in amount per unit of area) experienced by the enclosed sphere of the solid, at the different parts of its surface, when subjected to the stress.

Cor. 2 Any strain is fully specified by six quantities, viz., its three principal elongations, and three angles (θ, ϕ, ψ), or nine direction cosines, equivalent to three independent quantities specifying its axes

Def. 2 A stress and an infinitely small strain related in the manner defined in *Cor. 1*, are said to be of the same type. The ellipsoid by means of which the distribution of force over the surface of a sphere of unit radius is represented in one case, and by means of which the displacements of particles from the spherical surface are shown in the other, may be called the geometrical type of either.

Cor. Any stress- or strain-type is fully specified by five quantities, viz., two ratios between its principal strains or elongations and three quantities specifying the angular position of its axes

CHAPTER V. — Conditions of Perfect Concurrence between Stresses and Strains.

Def. 1. Two stresses are said to be coincident in direction, or to be perfectly concurrent, when they only differ in absolute magnitude. The same relative designations are applied to two strains differing from one another only in absolute magnitude.

Cor. If two stresses or two strains differ by one being reverse to the other, they may be said to be negatively coincident in direction, or to be directly opposed or directly contrary to one another.

Def. 2 When a homogeneous stress is such that the normal component of the mutual force between the parts of the body on the two sides of any plane whatever through it is proportional to the augmentation of distance between the same plane and another parallel to it and initially at unity of distance, due to a certain strain experienced by the same body, the stress and the strain are said to be perfectly concurrent; also to be coincident in direction. The body is said to be yielding directly to a stress applied to it, when it is acquiring a strain thus related to the stress; and in the same circumstances, the stress is said to be working directly on the body, or to be acting in the same direction as the strain

Cor. 1. Perfectly concurrent stresses and strains are of the same type.

Cor. 2 If a strain is of the same type as the stress, its reverse will be said to be negatively of the same type, or to be directly opposed to the strain. A body is said to be working directly against a stress applied to it when it is acquiring a strain directly opposed to the stress; and in the same circumstances, the matter round the body is said to be yielding directly to the reactive stress of the body upon it.

CHAPTER VI. — Orthogonal Stresses and Strains

Def. 1. A stress is said to act right across a strain, or to act orthogonally to a strain, or to be orthogonal to a strain, if work is neither done upon nor by the body in virtue of the action of the stress upon it while it is acquiring the strain.

Def. 2 Two stresses are said to be orthogonal when either coincides in direction with a strain orthogonal to the other

Def. 3 Two strains are said to be orthogonal when either coincides in direction with a stress orthogonal to the other

Examples — (1) A uniform cubical compression, and any strain involving no alteration of volume, are orthogonal to one another

(2) A simple extension or contraction in parallel lines unaccompanied by any transverse extension or contraction, that is, "a simple longitudinal strain," is orthogonal to any similar strain in lines at right angles to those parallels.

(3) A simple longitudinal strain is orthogonal to a "simple tangential strain" in which the sliding is parallel to its direction or at right angles to it

(4) Two infinitely small simple tangential strains in the same plane,¹ with their directions of sliding mutually inclined at an angle of 45° , are orthogonal to one another.

(5) An infinitely small simple tangential strain is orthogonal to every infinitely small simple tangential strain, in a plane either parallel to its plane of sliding or perpendicular to its line of sliding

CHAPTER VII — Composition and Resolution of Stresses and of Strains

Any number of simultaneously applied homogeneous stresses are equivalent to a single homogeneous stress which is called their resultant. Any number of superimposed homogeneous strains are equivalent to a single homogeneous resultant strain. Infinitely small strains may be independently superimposed; and in what follows it will be uniformly understood that the strains spoken of are infinitely small, unless the contrary is stated.

Examples — (1) A strain consisting simply of elongation in one set of parallel lines, and a strain consisting of equal contraction in a direction at right angles to it, applied together, constitute a single strain, of the kind which that described in Example (3) of the preceding chapter is when infinitely small, and is called a plane distortion, or a simple distortion. It is also sometimes called a simple tangential strain, and when so considered, its plane of sliding may be regarded as either of the planes bisecting the angles between planes normal to the lines of the component longitudinal strains.

(2) Any two simple distortions in one plane may be reduced to a single simple distortion in the same plane.

(3) Two simple distortions not in the same plane have for their resultant a strain which is a distortion unaccompanied by change of volume, and which may be called a compound distortion

(4) Three equal longitudinal elongations or condensations in three directions

¹ That is, a homogeneous strain in which all the particles in one plane remain fixed, and other particles are displaced parallel to this plane

² "The plane of a simple tangential strain," or the plane of distortion in a simple tangential strain, is a plane perpendicular to that of the particles supposed to be held fixed, and parallel to the lines of displacement of the others.

at right angles to one another are equivalent to a single dilatation or condensation equal in all directions. The single stress equivalent to three equal tensions or pressures in directions at right angles to one another is a negative or positive pressure equal in all directions.

(5) If a certain stress or infinitely small strain be defined (Chapter III. Cor. 3, or Chapter IV) by the ellipsoid

$$(1+A)X^2 + (1+B)Y^2 + (1+C)Z^2 + DYZ + EZX + FXY = 1,$$

and another stress or infinitely small strain by the ellipsoid

$$(1+A')X^2 + (1+B')Y^2 + (1+C')Z^2 + D'YZ + E'ZX + F'XY = 1,$$

where A, B, C, D, E, F , &c., are all infinitely small, their resultant stress or strain is that represented by the ellipsoid

$$(1+A+A')X^2 + (1+B+B')Y^2 + (1+C+C')Z^2 + (D+D')YZ + (E+E')ZX + (F+F')XY = 1.$$

CHAPTER VIII.—Specification of Strains and Stresses by their Components according to Chosen Types.

Prop. Six stresses or six strains of six distinct arbitrarily chosen types may be determined to fulfil the condition of having a given stress or a given strain for their resultant, provided those six types are so chosen that a strain belonging to any one of them cannot be the resultant of any strains whatever belonging to the others.

For, just six independent parameters being required to express any stress or strain whatever, the resultant of any set of stresses or strains may be made identical with a given stress or strain by fulfilling six equations among the parameters which they involve, and therefore the magnitudes of six stresses or strains belonging to the six arbitrarily chosen types may be determined, if their resultant be assumed to be identical with the given stress or strain.

Cor. Any stress or strain may be numerically specified in terms of numbers expressing the amounts of six stresses or strains of six arbitrarily chosen types which have it for their resultant.

Types arbitrarily chosen for this purpose will be called types of reference. The specifying elements of a stress or strain will be called its components according to types of reference. The specifying elements of a strain may also be called its coordinates, with reference to the chosen types.

Examples.—(1) Six strains in each of which one of the six edges of a tetrahedron of the solid is elongated while the others remain unchanged, may be used as types of reference for the specification of any kind of strain or stress. The ellipsoid representing any one of these six types will have its two circular sections parallel to the faces of the tetrahedron which do not contain the stretched side.

(2) Six strains consisting, any one of them, of an infinitely small alteration either of one of the three edges, or of one of the three angles between the faces, of a parallelepiped of the solid, while the other five angles and edges remain unchanged, may be taken as types of reference, for the specification of either stresses or strains. In some cases, as for instance in expressing the probable elastic properties of a crystal of Iceland spar, it might possibly be convenient to use an oblique parallelepiped for such a system of types of reference, but more frequently it will be convenient to adopt a system of types related to the deformations of a cube of the solid.

CHAPTER IX.—Orthogonal Types of Reference.

Def. A normal system of types of reference is one in which the strains or stresses of the different types are all six mutually orthogonal (fifteen conditions). A normal system of types of reference may also be called an orthogonal system. The elements specifying, with reference to such a system, any stress or strain, will be called orthogonal components or orthogonal coordinates.

Examples.—(1) The six types described in Example (2) of Chapter VIII are clearly orthogonal, if the parallelepiped referred to is rectangular. Three of these are simple longitudinal extensions, parallel to the three sets of rectangular edges of the parallelepiped. The remaining three are plane distortions parallel to the faces, their axes bisecting the angles between the edges. They constitute the system of types of reference uniformly used hitherto by writers on the theory of elasticity.

(2) The six strains in which a spherical portion of the solid is changed into ellipsoids having the following equations—

$$\begin{aligned}(1+A)X^2 + Y^2 + Z^2 &= 1 \\ X^2 + (1+B)Y^2 + Z^2 &= 1 \\ X^2 + Y^2 + (1+C)Z^2 &= 1 \\ X^2 + Y^2 + Z^2 + DYZ &= 1 \\ X^2 + Y^2 + Z^2 + EZX &= 1 \\ X^2 + Y^2 + Z^2 + FXY &= 1,\end{aligned}$$

are of the same kind as those considered in the preceding example, and therefore constitute a normal system of types of reference. The resultant of the strains specified, according to those equations, by the elements A, B, C, D, E, F , is a strain in which the sphere becomes an ellipsoid whose equation—see above, Chapter VII Ex. (5)—is

$$(1+A)X^2 + (1+B)Y^2 + (1+C)Z^2 + DYZ + EZX + FXY = 1$$

(3) A compression equal in all directions (I), three simple distortions having their planes at right angles to one another and their axes bisecting the angles between the lines of intersection of these planes (III) (IV) any simple or compound distortion consisting of a combination of longitudinal strains parallel to those lines of intersections (V), and the distortion (VI), constituted from the same elements which is orthogonal to the last, afford a system of six mutually orthogonal types which will be used as types of reference below in expressing the elasticity of cubically isotropic solids. (Compare Chapter X Example 7 below.)

¹ This example, as well as (7) of Chapter X. (5) to (X), and the example of Chapter XII, are intended to prepare for the application of the theory of Principal Elasticities to cubically and spherically isotropic bodies, in Part II. Chapter XV.

² The "axes of a simple distortion" are the lines of its two component longitudinal strains.

CHAPTER X.—On the Measurement of Strains and Stresses.

Def. Strains of any types are said to be to one another in the same ratios as stresses of the same types respectively, when any particular plane of the solid acquires, relatively to another plane parallel to it, motions in virtue of those strains which are to one another in the same ratios as the normal components of the forces between the parts of the solid on the two sides of either plane due to the respective stresses.

Def. The magnitude of a stress and of a strain of the same type are quantities which, multiplied one by the other, give the work done on unity of volume of a body acted on by the stress while acquiring the strain.

Cor. 1 If $x, y, z, \xi, \eta, \zeta$ denote orthogonal components of a certain strain, and if P, Q, R, S, T, U denote components, of the same type respectively, of a stress applied to a body while acquiring that strain, the work done upon it per unit of its volume will be

$$Px + Qy + Rz + S\xi + T\eta + U\zeta.$$

Cor. 2. The condition that two strains or stresses specified by $(x, y, z, \xi, \eta, \zeta)$ and $(x', y', z', \xi', \eta', \zeta')$, in terms of a normal system of types of reference, may be orthogonal to one another is

$$xx' + yy' + zz' + \xi\xi' + \eta\eta' + \zeta\zeta' = 0$$

Cor. 3. The magnitude of the resultant of two, three, four, five, or six mutually orthogonal strains or stresses is equal to the square root of the sum of their squares. For if P, Q , &c., denote several orthogonal stresses, and F the magnitude of their resultant, and x, y , &c., a set of proportional strains of the same types respectively, and r the magnitude of the single equivalent strain, the resultant stress and strain will be of one type, and therefore the work done by the resultant stress will be Fr . But the amounts done by the several components will be Px, Qy , &c., and therefore

$$Fr = Px + Qy + \&c.$$

Now we have, to express the proportionality of the stresses and strains,

$$\frac{P}{x} = \frac{Q}{y} = \&c. = \frac{F}{r}.$$

Each member must be equal to

$$\frac{P^2 + Q^2 + \&c.}{Px + Qy + \&c.};$$

and also equal to

$$\frac{Px + Qy + \&c.}{x^2 + y^2 + \&c.}$$

Hence

$$r = \frac{P^2 + Q^2 + \&c.}{Fr}, \text{ which gives } F^2 = P^2 + Q^2 + \&c.$$

and

$$\frac{F}{r} = \frac{Fr}{x^2 + y^2 + \&c.} \text{ which gives } r^2 = x^2 + y^2 + \&c.$$

Cor. 4. A definite stress of some particular type chosen arbitrarily may be called unity; and then the numerical reckoning of all strains and stresses becomes perfectly definite.

Def. A uniform pressure or tension in parallel lines, amounting in intensity to the unit of force per unit of area normal to it, will be called a stress of unit magnitude, and will be reckoned as positive when it is tension, and negative when pressure.

Examples.—(1) Hence the magnitude of a simple longitudinal strain, in which lines of the body parallel to a certain direction experience elongation to an extent bearing the ratio λ to their original dimensions, must be called λ .

(2) The magnitude of the single stress equivalent to three simple pressures in directions at right angles to one another each unity is $-\sqrt{3}$, a uniform compression in all directions of unity per unit of surface is a negative stress equal to $\sqrt{3}$ in absolute value.

(3) A uniform dilatation in all directions, in which linear dimensions are augmented in the ratio $1 + x$, is a strain equal in magnitude to $x/\sqrt{3}$, or a uniform "cubic expansion" E is a strain equal to $\frac{E}{\sqrt{3}}$.

(4) A stress compounded of unit pressure in one direction and an equal tension in a direction at right angles to it, or which is the same thing, a stress compounded of two balancing couples of unit tangential tensions in planes at angles of 45° to the direction of those forces, and at right angles to one another amounts in magnitude to $\sqrt{2}$.

(5) A strain compounded of a simple longitudinal extension x , and a simple longitudinal condensation of equal absolute value, in a direction perpendicular to it, is a strain of magnitude $x/\sqrt{2}$; or, which is the same thing (if $\sigma = 2x$), a simple distortion such that the relative motion of two planes at unit distances parallel to either of the planes bisecting the angles between the two planes mentioned above is a motion σ parallel to themselves, is a strain amounting in magnitude to $\frac{\sigma}{\sqrt{2}}$.

(6) If a strain be such that a sphere of unit radius in the body becomes an ellipsoid whose equation is

$$(1-A)X^2 + (1-B)Y^2 + (1-C)Z^2 - DYZ - EZX - FXY = 1,$$

the values of the component strains corresponding, as explained in Example (3) of Chap. IX., to the different coefficients respectively, are

$$\frac{1}{2}A, \frac{1}{2}B, \frac{1}{2}C, \frac{D}{2\sqrt{2}}, \frac{E}{2\sqrt{2}}, \frac{F}{2\sqrt{2}}.$$

For the components corresponding to A, B, C are simple longitudinal strains, in which diameters of the sphere along the axes of coordinates become elongated from 2 to $2+A, 2+B, 2+C$ respectively. D is a distortion in which diameters in the plane YOZ , bisecting the angles YOZ and XOZ , become respectively elongated and contracted from 2 to $2+D$, and from 2 to $2-D$, and so for the others. Hence, if we take $x, y, z, \xi, \eta, \zeta$ to denote the magnitudes of a

component strains, according to the orthogonal system of types described in Examples (1) and (2) of Chap. IX, the resultant strain equivalent to them will be one in which a sphere of radius 1 in the solid becomes an ellipsoid whose equation is

$$(1-2x)X^2 + (1-2y)Y^2 + (1-2z)Z^2 - 2\sqrt{2}(\xi YZ + \eta ZX + \zeta XY) = 1,$$

and its magnitude will be

$$\sqrt{(x^2 + y^2 + z^2 + \xi^2 + \eta^2 + \zeta^2)}.$$

(7) The specifications, according to the system of reference used in the preceding example, of the unit strains of the six orthogonal types defined in Example (2) of Chap. IX, are respectively as follows—

	x	y	z	ξ	η	ζ
(I)	$\frac{1}{\sqrt{3}}$	$\frac{1}{\sqrt{3}}$	$\frac{1}{\sqrt{3}}$	0	0	0
(II)	0	0	0	1	0	0
(III)	0	0	0	0	1	0
(IV)	0	0	0	0	0	1
(V)	l	m	n	0	0	0
(VI)	l'	m'	n'	0	0	0

where l, m, n, l', m', n' denote quantities fulfilling the following conditions—

$$l^2 + m^2 + n^2 = 1,$$

$$l' + m' + n' = 0,$$

$$ll' + mm' + nn' = 0,$$

$$l'^2 + m'^2 + n'^2 = 1,$$

$$l + m' + n = 0$$

$$(8) \text{ If } (1-2l)X^2 + (1-2m)Y^2 + (1-2n)Z^2 - 2\sqrt{2}(\xi YZ + \eta ZX + \zeta XY) = 1$$

be the equation of the ellipsoid representing a certain stress, the amount of work done by this stress, if applied to a body while acquiring the strain represented by the equation in the preceding example, will be

$$Px + Qy + Rz + S\xi + T\eta + U\zeta$$

Cor. Hence, if variables X, Y, Z be transformed in any other set (X', Y', Z') fulfilling the condition of being the coordinates of the same point, referred to another system of rectangular axes, the coefficients $x, y, z, \xi, \eta, \zeta, x', y', z', \xi', \eta', \zeta'$ in two homogeneous quadratic functions of three variables,

$$(1-2x)X^2 + (1-2y)Y^2 + (1-2z)Z^2 - 2\sqrt{2}(\xi YZ + \eta ZX + \zeta XY)$$

and

$$(1-2x')X'^2 + (1-2y')Y'^2 + (1-2z')Z'^2 - 2\sqrt{2}(\xi' Y'Z' + \eta' Z'X' + \zeta' X'Y'),$$

and the corresponding coefficients $x', y', z', \xi', \eta', \zeta', x'', y'', z'', \xi'', \eta'', \zeta''$ in these functions transformed to $x'', y'', z'', \xi'', \eta'', \zeta''$, will be so related that

$$x'x'' + y'y'' + z'z'' + \xi'\xi'' + \eta'\eta'' + \zeta'\zeta'' = xx'' + yy'' + zz'' + \xi\xi'' + \eta\eta'' + \zeta\zeta'',$$

or the function $xx'' + yy'' + zz'' + \xi\xi'' + \eta\eta'' + \zeta\zeta''$ of the coefficients is an "invariant" for linear transformations fulfilling the conditions of transformation from one to another set of rectangular axes. Since $x+y+z$ and $x+y+z$ are clearly invariant also, it follows that $AA' + BB' + CC' + 2DD' + 2EE' + 2FF'$ is an invariant function of the coefficients of the two quadratics

$$AX^2 + BY^2 + CZ^2 + 2DYZ + 2EZX + 2FXY$$

and

$$A'X'^2 + B'Y'^2 + C'Z'^2 + 2D'Y'Z' + 2E'Z'X' + 2F'X'Y',$$

which it is easily proved to be by direct transformation

This is the simplest form of the algebraic theorem of invariance with which we are concerned.

CHAPTER XI.—On Imperfect Concurrences of two Stress or Strain Types.

Def. The concurrence of any stresses or strains of two stated types is the proportion which the work done when a body of unit volume experiences a stress of either type, while acquiring a strain of the other, bears to the product of the numbers measuring the stress and strain respectively.

Cor. 1 In orthogonal resolution of a stress or strain, its component of any stated type is equal to its own amount multiplied by its concurrence with that type; or the stress or strain of a stated type which, along with another or others orthogonal to it, have a given stress or strain for their resultant, is equal to the amount of the given stress or strain reduced in the ratio of its concurrence with that stated type.

Cor. 2 The concurrence of two coincident stresses or strains is unity, or a perfect concurrence is numerically equal to unity.

Cor. 3 The concurrence of two orthogonal stresses and strains is zero.

Cor. 4 The concurrence of two directly opposite stresses or strains is -1.

Cor. 5 If $x, y, z, \xi, \eta, \zeta$ are orthogonal components of any stress, its concurrences with the types of reference are

$$\frac{x}{\sqrt{3}}, \frac{y}{\sqrt{3}}, \frac{z}{\sqrt{3}}, \frac{\xi}{\sqrt{3}}, \frac{\eta}{\sqrt{3}}, \frac{\zeta}{\sqrt{3}},$$

$$r = (x^2 + y^2 + z^2 + \xi^2 + \eta^2 + \zeta^2)^{\frac{1}{2}}$$

Cor. 6 The mutual concurrence of two stresses or strains is

$$ll' + mm' + nn' + \xi\xi' + \eta\eta' + \zeta\zeta'.$$

If $l, m, n, \xi, \eta, \zeta$ denote the concurrences of one of them with

six orthogonal types of reference, and $l', m', n', \xi', \eta', \zeta'$ those of the other.

Cor. 7 The most convenient specification of a type for strains or stresses, being in general a statement of the components, according to the types of reference, of a unit strain or stress of the type to be specified, becomes a statement of its concurrences with the types of reference when these are orthogonal.

Examples.—(1) The mutual concurrence of two simple longitudinal strains or stresses, inclined to one another at an angle θ , is $\cos^2 \theta$.

(2) The mutual concurrence of two simple distortions in the same plane, whose axes are inclined at an angle θ to one another, is $\cos^2 \theta - \sin^2 \theta$, or $2 \sin(45^\circ - \theta) \cos(45^\circ - \theta)$.

Hence the components of a simple distortion δ along two rectangular axes in its plane, and two others bisecting the angle between these taken as axes of component simple distortions, are

$$\delta(\cos^2 \theta - \sin^2 \theta) \text{ and } \delta 2 \sin \theta \cos \theta$$

respectively, if θ be the angle between the axis of elongation in the given distortion and in the first component type.

(3) The mutual concurrence of a simple longitudinal strain and a simple distortion is

$$\sqrt{2} \cos \alpha \cos \beta,$$

If α and β be the angles at which the direction of the longitudinal strain is inclined to the line bisecting the angles between the axes of the distortion. It is also equal to

$$\frac{1}{\sqrt{2}} (\cos^2 \phi - \cos^2 \psi),$$

If ϕ and ψ denote the angles at which the direction of the longitudinal strain is inclined to the axes of the distortion.

(4) The mutual concurrence of a simple longitudinal strain and of a uniform dilatation is $\frac{1}{\sqrt{3}}$.

(5) The specifying elements exhibited in Example (7) of the preceding Chapter are the concurrences of the new system of orthogonal types described in Example (3) of Chap. IX, with the ordinary system, Examples (1) and (2), Chap. IX.

CHAPTER XII.—On the Transformation of Types of Reference for Stresses or Strains

To transform the specification ($x, y, z, \xi, \eta, \zeta$) of a stress or strain with reference to one system of types into ($x_1, x_2, x_3, x_4, x_5, x_6$) with reference to another system of types. Let ($a_1, b_1, c_1, d_1, e_1, f_1$) be the components, according to the original system, of a unit strain of the first type of the new system, let ($a_2, b_2, c_2, d_2, e_2, f_2$) be the corresponding specification of the second type of the new system, and so on. Then we have, for the required formulae of transformation—

$$x = a_1 x_1 + a_2 x_2 + a_3 x_3 + a_4 x_4 + a_5 x_5 + a_6 x_6,$$

$$y = b_1 x_1 + b_2 x_2 + b_3 x_3 + b_4 x_4 + b_5 x_5 + b_6 x_6,$$

$$z = c_1 x_1 + c_2 x_2 + c_3 x_3 + c_4 x_4 + c_5 x_5 + c_6 x_6,$$

$$\xi = d_1 x_1 + d_2 x_2 + d_3 x_3 + d_4 x_4 + d_5 x_5 + d_6 x_6,$$

$$\eta = e_1 x_1 + e_2 x_2 + e_3 x_3 + e_4 x_4 + e_5 x_5 + e_6 x_6,$$

$$\zeta = f_1 x_1 + f_2 x_2 + f_3 x_3 + f_4 x_4 + f_5 x_5 + f_6 x_6.$$

Example.—The transforming equations to pass from a specification ($x, y, z, \xi, \eta, \zeta$) in terms of the system of reference used in Examples (6) and (7), Chapter X, to a specification ($\sigma, \xi, \eta, \zeta, \omega$) in terms of the new system described in Example (3) of Chapter IX, and specified in Example (7) of Chapter X, are as follows—

$$x = \frac{1}{\sqrt{3}} \sigma + l \omega + l' \omega,$$

$$y = \frac{1}{\sqrt{3}} \sigma + m \omega + m' \omega$$

$$z = \frac{1}{\sqrt{3}} \sigma + n \omega + n' \omega,$$

$$\xi = \xi, \eta = \eta, \zeta = \zeta;$$

where, as before stated, l, m, n, l', m', n' are by quantities fulfilling the conditions

$$l^2 + m^2 + n^2 = 1,$$

$$l' + m' + n' = 0,$$

$$l^2 + m^2 + n^2 = 1,$$

$$l' + m' + n' = 0,$$

$$ll' + mm' + nn' = 0.$$

PART II.—ON THE DYNAMICAL RELATIONS BETWEEN STRESSES AND STRAINS EXPERIENCED BY AN ELASTIC SOLID.

CHAPTER XIII.—Interpretation of the Differential Equation of Energy.

In a paper on the Thermo-elastic Properties of Matter, published in the first number of the *Quarterly Mathematical Journal*, April 1855, and republished in the *Philosophical Magazine*, 1877, second half year, it was proved, from general principles in the theory of the Transformation of Energy, that the amount of work (w) required to reduce an elastic solid, kept at a constant temperature, from one stated condition of internal strain to another depends solely on these two conditions, and not at all on the cycle of varied states through which the body may have been made to pass in effecting the change, provided always there has been no failure in

the elasticity under any of the strains it has experienced. Thus for a homogeneous solid homogeneously strained, it appears that w is a function of six independent variables $x, y, z, \xi, \eta, \zeta$, by which the condition of the solid as to strain is specified. Hence to strain the body to the infinitely small extent expressed by the variation from $(x, y, z, \xi, \eta, \zeta)$ to $(x+dx, y+dy, z+dz, \xi+d\xi, \eta+d\eta, \zeta+d\zeta)$, the work required to be done upon it is

$$\frac{dw}{dx}dx + \frac{dw}{dy}dy + \frac{dw}{dz}dz + \frac{dw}{d\xi}d\xi + \frac{dw}{d\eta}d\eta + \frac{dw}{d\zeta}d\zeta.$$

The stress which must be applied to its surface to keep the body in equilibrium in the state $(x, y, z, \xi, \eta, \zeta)$ must therefore be such that it would do this amount of work if the body, under its action, were to acquire the arbitrary strain $dx, dy, dz, d\xi, d\eta, d\zeta$; that is, it must be the resultant of six stresses—one orthogonal to the five strains $dy, dz, d\xi, d\eta, d\zeta$, and of such a magnitude as to do the work $\frac{dw}{dx}dx$ when the body acquires the strain dx , a second orthogonal to $dx, dz, d\xi, d\eta, d\zeta$, and of such a magnitude as to do the work $\frac{dw}{dy}dy$ when the body acquires the strain dy , and so on.

If a, b, c, f, g, h denote the respective concurrences of these six stresses, with the types of reference used in the specification $(x, y, z, \xi, \eta, \zeta)$ of the strains, the amounts of the six stresses which fulfil these conditions will (Chapter XI) be given by the equations

$$P = \frac{1}{a} \frac{dw}{dx}, \quad Q = \frac{1}{b} \frac{dw}{dy}, \quad R = \frac{1}{c} \frac{dw}{dz},$$

$$S = \frac{1}{f} \frac{dw}{d\xi}, \quad T = \frac{1}{g} \frac{dw}{d\eta}, \quad U = \frac{1}{h} \frac{dw}{d\zeta},$$

and the types of these component stresses are determined by being orthogonal to the five of the six strain-types, wanting the first, the second, &c., respectively.

Cor. If the types of reference used in expressing the strain of the body constitute an orthogonal system, the types of the component stresses will coincide with them, and each of the concurrences will be unity. Hence the equations of equilibrium of an elastic solid referred to six orthogonal types are simply

$$P = \frac{dw}{dx}, \quad Q = \frac{dw}{dy}, \quad R = \frac{dw}{dz},$$

$$S = \frac{dw}{d\xi}, \quad T = \frac{dw}{d\eta}, \quad U = \frac{dw}{d\zeta}.$$

CHAPTER XIV.—Reduction of the Potential Function, and of the Equations of Equilibrium, of an Elastic Solid to their simplest Forms

If the condition of the body from which the work denoted by w is reckoned be that of equilibrium under no stress from without, and if $x, y, z, \xi, \eta, \zeta$ be chosen each zero for this condition, we shall have, by Maclaurin's theorem,

$$w = H_2(x, y, z, \xi, \eta, \zeta) + H_3(x, y, z, \xi, \eta, \zeta) + \&c.$$

where H_2, H_3 , &c., denote homogeneous functions of the second order, third order, &c., respectively. Hence $\frac{dw}{dx}, \frac{dw}{dy}$, &c., will each be a linear function of the strain coordinates, together with functions of higher orders derived from H_3 , &c. But experience shows (section 37 above) that, within the elastic limits, the stresses are very nearly if not quite proportional to the strains they are capable of producing; and therefore H_3 , &c., may be neglected, and we have simply

$$w = H_2(x, y, z, \xi, \eta, \zeta).$$

Now in general there will be twenty-one terms, with independent coefficients, in this function; but by a choice of types of reference, that is, by a linear transformation of the independent variables, we may, in an infinite variety of ways, reduce it to the form

$$w = \frac{1}{2}(Ax^2 + By^2 + Cz^2 + F\xi^2 + G\eta^2 + H\zeta^2).$$

The equations of equilibrium then become

$$P = \frac{A}{a}x, \quad Q = \frac{B}{b}y, \quad R = \frac{C}{c}z,$$

$$S = \frac{F}{f}\xi, \quad T = \frac{G}{g}\eta, \quad U = \frac{H}{h}\zeta,$$

the simplest possible form under which they can be presented. The interpretation can be expressed as follows

Prop. An infinite number of systems of six types of strains or stresses exist in any given elastic solid such that, if a strain of any one of those types be impressed on the body, the elastic reaction is balanced by a stress orthogonal to the five others of the same system

CHAPTER XV.—On the Six Principal Strains of an Elastic Solid.

To reduce the twenty-one coefficients of the quadratic terms in the expression for the potential energy to six by a linear transforma-

tion, we have only fifteen equations to satisfy; while we have thirty disposable transforming coefficients, there being five independent elements to specify a type, and six types to be changed. Any further condition expressible by just fifteen independent equations may be satisfied, and makes the transformation determinate. Now the condition that six strains may be mutually orthogonal is expressible by just as many equations as there are different pairs of six things, that is, fifteen. The well-known algebraic theory of the linear transformation of quadratic functions shows for the case of six variables—(1) that the six coefficients in the reduced form are the roots of a "determinant" of the sixth degree necessarily real, (2) that this multiplicity of roots leads determinately to one, and only one system of six types fulfilling the prescribed conditions, unless two or more of the roots are equal to one another, when there will be an infinite number of solutions and definite degrees of isotropy among them, and (3) that there is no equality between any of the six roots of the determinant in general, when there are twenty-one independent coefficients in the given quadratic.

Prop. Hence a single system of six mutually orthogonal types may be determined for any homogeneous elastic solid, so that its potential energy when homogeneously strained in any way is expressed by the sum of the products of the squares of the components of the strain, according to those types, respectively multiplied by six determinate coefficients

Def. The six strain-types thus determined are called the Six Principal Strain-types of the body.

The concurrences of the stress-components used in interpreting the differential equation of energy with the types of the strain-coordinates in terms of which the potential of elasticity is expressed, being perfect when these constitute an orthogonal system, each of the quantities denoted above by a, b, c, f, g, h , is unity when the six principal strain-types are chosen for the coordinates. The equations of equilibrium of an elastic solid may therefore be expressed as follows.—

$$P = Ax, \quad Q = By, \quad R = Cz,$$

$$S = F\xi, \quad T = G\eta, \quad U = H\zeta,$$

where $x, y, z, \xi, \eta, \zeta$ denote strains belonging to the six Principal Types, and P, Q, R, S, T, U the components according to the same types, of the stress required to hold the body in equilibrium when in the condition of having those strains. The amount of work that must be spent upon it per unit of its volume, to bring it to this state from an unconstrained condition, is given by the equation

$$w = \frac{1}{2}(Ax^2 + By^2 + Cz^2 + F\xi^2 + G\eta^2 + H\zeta^2)$$

Def. The coefficients A, B, C, F, G, H are called the six Principal Elasticities of the body

The equations of equilibrium express the following propositions—

Prop. If a body be strained according to any one of its six Principal Types, the stress required to hold it so is directly concurrent with the strain

Examples—(1) If a solid be cubically isotropic in its elastic properties, as crystals of the cubic class probably are, any portion of it will, when subject to a uniform positive or negative normal pressure all round its surface, experience a uniform condensation or dilation in all directions. Hence a uniform condensation is one of its six principal strains. Three plane distortions with axes bisecting the angles between the edges of the cube of symmetry are clearly also principal strains, and since the three corresponding principal elasticities are equal to one another, any strain whatever compounded of these three is a principal strain. Lastly, a plane distortion whose axis coincides with any two edges of the cube, being clearly a principal distortion, and the principal elasticities corresponding to the three distortions of this kind being equal to one another, any distortion compounded of them is also a principal distortion.

Hence the system of orthogonal types treated of in Examples (3) Chap. IX., and (7) Chap. X., or any system in which, for (II), (III), and (IV), any three orthogonal strains compounded of them are substituted, constitutes a system of six Principal Strains in a solid cubically isotropic. There are only three distinct Principal Elasticities for such a body, and these are—(A) its modulus of compressibility, (B) its rigidity against diagonal distortion in any of its principal planes (three equal elasticities), and (C) its rigidity against rectangular distortions of a cube of symmetry (two equal elasticities).

(2) In a perfectly isotropic solid, the rigidity against all distortions is equal. Hence the rigidity (B) against diagonal distortion must be equal to the rigidity (C) against rectangular distortion, in a cube, and it is easily seen that if this condition is fulfilled for one set of three rectangular planes for which a substance is isotropic, the isotropy must be complete. The conditions of perfect or spherical isotropy are therefore expressed in terms of the conditions referred to in the preceding example, with the further condition $B=C$.

A uniform condensation in all directions, and any system whatever of five orthogonal distortions, constitute a system of six Principal Strains in a spherically isotropic solid. Its Principal Elasticities are simply its Modulus of Compressibility and its Rigidity.

Prop. Unless some of the six Principal Elasticities be equal to one another, the stress required to keep the body strained otherwise than according to one or other of six distinct types is oblique to the strain.

Prop. The stress required to maintain a given amount of strain is a maximum or a maximum-minimum, or a minimum, if it is of one of the six Principal Types

Cor. If A be the greatest and H the least of the six quantities A, B, C, F, G, H , the principal type to which the first corresponds is that of a strain requiring a greater stress to maintain it than any

other strain of equal amount; and the principal type to which the last corresponds is that of a strain which is *maintained by a less stress* than any other strain of equal amount in the same body. The stresses corresponding to the four other principal strain-types have each the maximum-minimum property in a determinate way.

Prop If a body be strained in the direction of which the concurrences with the principal strain-types are $l, m, n, \lambda, \mu, \nu$, and to an amount equal to r , the stress required to maintain it in this state will be equal to Ωr , where

$$\Omega = (A^2 l^2 + B^2 m^2 + C^2 n^2 + F^2 \lambda^2 + G^2 \mu^2 + H^2 \nu^2)^{\frac{1}{2}},$$

and will be of a type of which the concurrences with the principal types are respectively

$$\frac{Al}{\Omega}, \frac{Bm}{\Omega}, \frac{Cn}{\Omega}, \frac{F\lambda}{\Omega}, \frac{G\mu}{\Omega}, \frac{H\nu}{\Omega}.$$

Prop A homogeneous elastic solid, crystalline or non-crystalline, subject to magnetic force or free from magnetic force, has neither any right-handed or left-handed, nor any dipolar, properties dependent on elastic forces simply proportional to strains.

Cor The elastic forces concerned in the luminiferous vibrations of a solid or fluid medium possessing the right- or left-handed property, whether axial or rotatory, such as quartz crystal, or tartaric acid, or solution of sugar, either depend on the heterogeneity or on the magnitude of the strains experienced.

Hence as they do not depend on the magnitude of the strain, they do depend on its heterogeneity through the portion of a medium containing a wave

Cor There cannot possibly be any characteristic of elastic forces simply proportional to the strains in a homogeneous body, corresponding to certain peculiarities of crystalline form which have been observed,—for instance corresponding to the plagiodal faces discovered by Sir John Herschel to indicate the optical character, whether right-handed or left-handed, in different specimens of quartz crystal, or corresponding to the distinguishing characteristics of the crystals of the right-handed and left-handed tartaric acids obtained by M. Pasteur from racemic acid, or corresponding to the dipolar characteristics of form said to have been discovered in electric crystals.

CHAPTER XVI — Application of Conclusions to Natural Crystals

It is easy to demonstrate that a body, homogeneous when regarded on a large scale, may be constructed to have twenty-one arbitrarily prescribed values for the coefficients in the expression for its potential energy in terms of any prescribed system of strain coordinates. This proposition was first enunciated in the paper on the Thermo-elastic Properties of Solids, published April 1855, in the *Quarterly Mathematical Journal* alluded to above. We may infer the following

Prop A solid may be constructed to have arbitrarily prescribed values for its six Principal Elasticities and an arbitrary orthogonal system of six strain-types, specified by fifteen independent elements, for its principal strains—for instance, five arbitrarily chosen systems of three rectangular axes, for the normal axes of five of the Principal Types, those of the sixth consequently in general distinct from all the others, and determinate, and the six times two ratios between the three stresses or strains of each type, also determinate. The fifteen equations expressing (Chap. VI.) the mutual orthogonality of the six types determine the twelve ratios for the six types, and the three quantities specifying the axes of the sixth type in the particular case here suggested or generally the fifteen equations determine fifteen out of the thirty quantities (viz twelve ratios and eighteen angular coordinates) specifying six Principal Types

Cor There is no reason for believing that natural crystals do not exist for which there are six unequal Principal Elasticities, and six distinct strain-types for which the three normal axes constitute six distinct sets of three principal rectangular axes of elasticity.

It is easy to give arbitrary illustrative examples regarding Principal Elasticities also, to investigate the principal strain-types and the equations of elastic force referred to them or to other natural types, for a body possessing the kind of symmetry as to elastic forces that is possessed by a crystal of Iceland spar, or by a crystal of the "tesseral class," or of the included "cubical class." Such illustrations and developments, though proper for a students' text book of the subject, are unnecessary here.

For applications of the Mathematical Theory of Elasticity to the question of the earth's rigidity and elasticity as a whole, and to the equilibrium of elastic solids in general, which are beyond the scope of the present article, the reader is referred to Thomson and Tait's *Natural Philosophy*, §§ 588, 740, 832, 849, and Appendix C.

CHAPTER XVII — Plane Waves in a Homogeneous Isotropic Solid

A plane wave in a homogeneous elastic solid is a motion in which every line of particles in a plane parallel to one fixed plane ex-

periences simply a motion of translation—but a motion differing from the motions of particles in planes parallel to the same. Let OX, OY, OZ be three fixed rectangular axes; OX perpendicular to the wave front (as any of the parallel planes of moving particles referred to in the definition is called), and OY, OZ in the wave front. Let $x+u, y+v, z+w$ be the coordinates at time t of a particle which, if the solid were free from strain, would be at (x, y, z) . The definition of wave motion amounts simply to this, that u, v, w are functions of x and t .

The strain of the solid (Chap. VII. above) is the resultant of a simple longitudinal strain in the direction OX, equal to $\frac{du}{dx}$, and

two differential slips $\frac{dv}{dx}, \frac{dw}{dx}$, parallel to OY and OZ, constituting simple distortions of which the numerical magnitudes (Chap. X) are

$$\frac{dv}{dx}\sqrt{2}, \quad \text{and} \quad \frac{dw}{dx}\sqrt{2}$$

Put then

$$\frac{du}{dx} = \xi, \quad \frac{dv}{dx}\sqrt{2} = \eta, \quad \frac{dw}{dx}\sqrt{2} = \zeta \quad \dots (1);$$

and let W denote the work per unit of bulk required to produce the strain represented by this notation. We have (Chap. XV.)

$$W = \frac{1}{2}(A\xi^2 + B\eta^2 + C\zeta^2 + 2D\eta\zeta + 2E\xi\zeta + 2F\xi\eta) \dots (2),$$

where A, B, C, D, E, F denote modulus of elasticity of the solid. Let p, q, r denote the three components of the traction per unit area of the wave front. We have (Chap. XV.)

$$\left. \begin{aligned} p &= A\xi + F\eta + E\zeta \\ q\sqrt{2} &= F\xi + B\eta + D\zeta \\ r\sqrt{2} &= E\xi + D\eta + C\zeta \end{aligned} \right\} \dots (3),$$

Now let ξ, η, ζ be taken such that

$$\left. \begin{aligned} A\xi + F\eta + E\zeta &= M\xi \\ F\xi + B\eta + D\zeta &= M\eta \\ E\xi + D\eta + C\zeta &= M\zeta \end{aligned} \right\} \dots (4)$$

the determinantal cubic gives three real positive values for M , and with M equal to any one of these values, (4) determine the ratios ξ, η, ζ . Hence when the solid is strained in any one of the three ways thus determined we have

$$p = M\frac{du}{dx}, \quad q = M\frac{dv}{dx}, \quad r = M\frac{dw}{dx} \dots (5).$$

The three components of the whole force due to the tractions on the sides of an infinitely small parallelepiped $\delta x, \delta y, \delta z$ of the solid are clearly

$$\frac{\partial p}{\partial x}\delta x\delta y\delta z, \quad \frac{\partial q}{\partial x}\delta x\delta y\delta z, \quad \text{and} \quad \frac{\partial r}{\partial x}\delta x\delta y\delta z \dots (6),$$

and therefore, if ρ be its density, and consequently $\rho\delta x\delta y\delta z$ its mass, the equations of its motion are

$$\rho\frac{d^2u}{dt^2} = \frac{\partial p}{\partial x}, \quad \rho\frac{d^2v}{dt^2} = \frac{\partial q}{\partial x}, \quad \rho\frac{d^2w}{dt^2} = \frac{\partial r}{\partial x} \dots (7).$$

These, putting for p, q, r their values by (5), become

$$\rho\frac{d^2u}{dt^2} = M\frac{d^2u}{dx^2}, \quad \rho\frac{d^2v}{dt^2} = M\frac{d^2v}{dx^2}, \quad \rho\frac{d^2w}{dt^2} = M\frac{d^2w}{dx^2} \dots (8)$$

And by (4) and (1) we have

$$\left. \begin{aligned} Au + (Fv + Ew)\sqrt{2} &= Mu \\ Fu + (Bv + Dw)\sqrt{2} &= Mv\sqrt{2} \\ Eu + (Dv + Cw)\sqrt{2} &= Mw\sqrt{2} \end{aligned} \right\} \dots (9).$$

Let M_1, M_2, M_3 be the three roots of the determinantal cubic, and $b_1, c_1, b_2, c_2, b_3, c_3$, the corresponding values of the ratios $\frac{v}{u}, \frac{w}{u}$ determined by (9). The complete solution of (8), subject to (9), is

$$\left. \begin{aligned} u &= u_1 + u_2 + u_3 \\ v &= b_1 u_1 + b_2 u_2 + b_3 u_3 \\ w &= c_1 u_1 + c_2 u_2 + c_3 u_3 \end{aligned} \right\} \text{where} \quad \left. \begin{aligned} u_1 &= f_1\left(x + \sqrt{\frac{M_1}{\rho}}t\right) + F_1\left(x - \sqrt{\frac{M_1}{\rho}}t\right) \\ u_2 &= f_2\left(x + \sqrt{\frac{M_2}{\rho}}t\right) + F_2\left(x - \sqrt{\frac{M_2}{\rho}}t\right) \\ u_3 &= f_3\left(x + \sqrt{\frac{M_3}{\rho}}t\right) + F_3\left(x - \sqrt{\frac{M_3}{\rho}}t\right) \end{aligned} \right\} \dots (10),$$

$f_1, F_1, f_2, F_2, f_3, F_3$ denoting arbitrary functions. Hence we conclude that there are three different wave-velocities,

$$\sqrt{\frac{M_1}{\rho}}, \quad \sqrt{\frac{M_2}{\rho}}, \quad \sqrt{\frac{M_3}{\rho}}$$

and three different modes of waves, determined by equations (9)

Waves in an Isotropic Solid—If the solid be isotropic, we have

$$\left. \begin{aligned} B &= C \\ D &= E = F = 0 \\ M_1 &= A, \quad M_2 = M_3 = B \end{aligned} \right\} \dots (11)$$

Hence, instead of three different waves with different velocities, we have just two,—a wave (like that of sound in air or other elastic fluid) in which the motions are perpendicular to the wave front, and the other (like the waves of light in an isotropic medium) in which the motions are parallel to the wave front.

*Waves in an Incompressible Solid (Eolotropic or Isotropic).—*If the solid be incompressible, we have $A = \infty$, and μ must be zero.

Hence

$$W = D\eta^2 + C\zeta^2 + 2D\eta\zeta$$

and by a determinantal quadratic, instead of cubic, we find two wave-velocities and two wave-modes, in each of which the motion is parallel to the wave front. In the case of isotropy the two wave velocities are equal.

It is to be noticed that M_1 , M_2 , M_3 in the preceding investigation are not generally true "principal modulus," but special modulus corresponding to the particular plane chosen for the wave front. In the particular case of isotropy, however, the equal modulus M_2 , M_3 of (11) are principal modulus, being each equal to the modulus of rigidity, but M_1 is a mixed modulus of compressibility and rigidity—not a principal modulus. In the case of incompressibility, the two modulus found from the determinantal quadratic by the process indicated above are not principal modulus generally, because the distortions by the differential motions of planes of particles parallel to the wave front must generally give rise to tangential stresses orthogonal to them, which do not influence the wave motion.

(W. TH.)

ELATERIUM, a drug consisting of a sediment deposited by the juice of the fruit of *Ecbalium Elaterium*, the squirting cucumber (see vol. vi. p. 688.) To prepare it, the fruit is sliced lengthwise and slightly pressed; the greenish and slightly turbid juice thus obtained is strained and set aside; and the deposit of elaterium formed after a few hours is collected on a linen filter, rapidly drained, and dried on porous tiles at a gentle heat. Elaterium is met with in commerce in light, thin, friable, flat or slightly incurved opaque cakes, of a greyish-green colour, bitter taste, and tea-like smell. The best kind is the English, prepared at Hitchin, Market Deeping, Mitcham, and elsewhere; the Maltese is generally very inferior. Elaterium is an exceedingly powerful hydragogue and drastic purgative, and not unfrequently produces vomiting. Its active principal is *elaterin*, a crystallizable body of the formula $C_{20}H_{25}O_5$.

ELBA, the *Αἰθάλια* of the Greeks, and *Iva* of the Romans, is an island in the Mediterranean Sea, forming part of the Italian province of Livorno, and lying about 6 miles from the mainland of Italy, from which it is separated by the channel of Piombino, and about 34 miles E. of Corsica. It has a very irregular coast outline, is 18 miles long and $2\frac{1}{4}$ to $10\frac{1}{2}$ miles broad, and has a total area of nearly 90 square miles. It is throughout mountainous, and the highest point, Monte Capanne, is 2925 feet above sea-level. The western portion of the island is granitic, the eastern consists mainly of the sandstone locally known as *verrucano*, which in some places passes into a talc slate. In the vicinity of Porto Ferrajo the hills are cretaceous. The climate is mild, and, except at some spots on the coast, healthy. Springs are numerous, and the soil is not infertile; but agriculture and cattle-rearing are neglected, and there are no manufactures. Wine, wheat, aloes, dyer's lichen, and olives and other fruits are produced. The sardine and tunny fisheries, and the manufacture of sea-salt are of some importance; but the principal industry is mining. The iron mines are mostly in the vicinity of Rio Inferiore, and yield abundance of ore, chiefly hematite, of excellent quality. On account of the lack of fuel the ore is not smelted on the island, but is shipped direct to Follonica on the neighbouring coast of Italy, and to the ports of France and England. Marble, alabaster, sulphur, and ores of tin, lead, and silver are among the other mineral products. The principal places in Elba are the chief town Porto Ferrajo, with about 5000 inhabitants, the residence of Napoleon from May 4, 1814, to February 26, 1815, Rio Ferrajo, San Pietro, Porto Longone, and the village of Capoliveri. The population of the island in 1871 was 21,765.

The Argonauts, in quest of Circe are said to have landed at Portus Argous (*Αργῶος λιμήν*), now Porto Ferrajo, in Elba. The island was early famous for the richness of its mines, alluded to by Virgil (*Æn* x 178). It was attacked by Phayllus with a Syracusan fleet, 453 B.C., and subsequently by Apelles, who is stated to have subjugated it. In the 10th century it became a possession of the Pisans, from whom it was taken by the Genoese in 1290. It fell

eventually into Spanish hands, came in 1736 under the jurisdiction of Naples, and in 1801 was ceded to the king of Etruria by the treaty of Lunéville. It was united to France in 1803, made over to Napoleon by the Treaty of Paris in 1814, restored to Tuscany in the following year, and in 1860 annexed to Italy.

ELBE, the *Albis* of the Romans and the *Labe* of the Bohemians, a large river of Germany, with a total length of 705 miles, and a drainage area of about 55,000 square miles. It rises in Bohemia not far from the frontiers of Silesia, on the southern side of the Riesengebirge or Giants' Mountains, in $50^{\circ} 46' N.$ lat. and $15^{\circ} 32' E.$ long. Of the numerous small streams (Seifen or Flessen, as they are named in the district) whose confluent waters compose the infant river, the most important are the Weisswasser, or White Water, and the Elbseifen; the former rises to the S.W. of the Schneekuppe in the White Meadow, and the latter in a stone fountain in the Elb Meadow. Augmented successively by the Adler, the Iser, the Moldau, and the Eger, it cuts its way through the Mittelgebirge of Bohemia, traverses the sandstone mountains of Saxon Switzerland, and with a general N.W. direction continues to meander through Saxony, Anhalt, and Hanover, until at length it falls into the German Ocean about $53^{\circ} 5' N.$ lat. and $8^{\circ} 50' E.$ long. The principal towns on its banks are Leitmeritz, Pirna, Dresden, Meissen, Torgau, Wittenberg, Magdeburg, Wittenberge, Harburg, Hamburg, and Altona. A short distance above Hamburg the stream divides into a number of branches, but they all reunite before reaching the ocean. At its source the Elbe is about 4600 feet above the level of the sea; after the first 40 miles of its course it is still 658 feet; but at Dresden it is only 279, and at Arneburg in Brandenburg only 176. At Königgratz the width is about 100 feet, at the mouth of the Moldau about 300, at Dresden 960, and at Magdeburg over 1000. The tide is perceptible as far up as Geesthacht. Of the fifty and more tributaries belonging to the system the most important are the Moldau, the Eger, the Mulde, and the Saale,—the Moldau having a course of 267 miles, the Eger of 235, the Mulde of 185, and the Saale of 220. Though the channel in some places, and especially in the estuary, is encumbered with sandbanks and shallows, the Elbe is of great importance as a means of communication, steamboats being able to ascend the main stream as far as Melnick, and to reach Prague by means of the Moldau. Some idea of the extent of its traffic may be obtained from the statement that in 1870 at Schandau 489 passenger-steamers and 2658 vessels and barges of various kinds passed up the stream, and 489 passenger steamers, 2865 ships, and 1505 rafts down the stream. By one line of canal it communicates with Lübeck, by another with Bremen, and by others with the great network of Mecklenburg and Brandenburg; and several new lines are projected, by which a direct way will be opened up to Hanover, Leipsic, and various other important cities.—For details see Dr Th. H. Schunk's "Die Schiffahrts-Kanäle im Deutschen Reich," in Petermann's *Mittheil*, 1877.

Formerly 3 entrepôts (Pirnå, Dresden, and Magdeburg), 35 tolls, and numerous corporations of privileged watermen, opposed almost insurmountable obstacles to the navigation; the Austrians and the Saxons alone could navigate the Upper Elbe, that is, from Magdeburg to where it ceases to be navigable, and the Prussians and Hamburgers had the sole privilege of navigating the Lower Elbe. But new regulations were introduced by a convention concluded on the 13th June 1821 between all the bordering states, viz., Austria, Saxony, Prussia, Hanover, Denmark (for Holstein and Lauenburg), the grand duchy of Mecklenburg-Schwerin, and the three principalities of Anhalt. Every merchant, to whatever bordering state he might belong, was allowed with his own vessel and crew to navigate the whole course of the river without interruption, the 35 tolls were reduced to 14, the heavy dues which were levied upon goods of the first necessity were reduced to one for the cargo (*Elbe Toll*) and another for the ship (*Recognitionsgeld*); and each state was bound to watch over the portion of river which passed through their territories, and to preserve it from everything injurious to commerce or navigation. It was also arranged that a commission should meet from time to time for the revision of the tariff, &c., and the investigation of all matters connected with the utilization of the river. By the second of these commissions, which met at Dresden in 1842, an additional Navigation Act was published in 1844; in the third, at Magdeburg in 1850, it was proposed by Austria to remove the Elbe tolls altogether, but Hanover and some other states refused, in the fourth, at Hamburg, 1858, the same objections still carried the day; but in 1861 the fifth commission decided that only one common toll for all the riparian states should be left at Wittenberge, and after numerous difficulties, the federative council of the German empire succeeded in securing the complete freedom of the river in 1870. A compensation of 1,000,000 thalers was granted to Mecklenburg-Schwerin, and of 85,000 to Anhalt.

ELBERFELD, a manufacturing town of Rhenish Prussia in the government of Düsseldorf, situated in the narrow valley of the Wupper, about 19 miles E of the town of Düsseldorf on the Berg and Mark railway. Though for the most part of modern erection, it has a large number of irregular and narrow streets, and altogether presents rather an unprepossessing appearance; the very river, polluted as it is with the refuse of dye-works and factories, rather

increasing the unsanitariness. The newer quarters, however, must be excepted from this description, and many of the public buildings are large and handsome. Of these the most important are the town-house, in the modern Romanesque style, the provincial court, the exchange, the post office, the orphanage, the lunatic asylum, St Joseph's hospital, the infirmary, the Female Society's hospital, the railway company's offices, the gymnasium, and the technical school. The educational institutions include 27 popular schools where no fees are paid, and the whole system of relief for the poor is so well arranged that it has excited imitation in several towns in Germany. A great variety

of textile fabrics in cotton, wool, and silk are manufactured on an extensive scale; and besides dye-works and chemical works of proportionate importance, there may be mentioned button-factories, lace-factories, a brewery, a foundry, and soap-works. The town is the seat of a considerable number of industrial, philanthropic, intellectual, and religious institutions, among which the most noticeable are the public library, the museum, and the Berg Bible Society. The inhabitants are mainly Protestants, with a strong tendency towards pietism, but the Roman Catholics number upwards of 14,000, and the Jewish community has recently erected a new synagogue. The *Elberfelder Zeitung* and several other newspapers are published in the town. In 1840 the population was 31,514; in 1864, 63,300; and in 1875, 80,599.

The site of Elberfeld was marked in the 12th century by a castle belonging to the lords of Elberfeld, which was afterwards united with the Berg possessions, and held by the family of Nesselrode; but it was not till the 16th century that the nucleus of the present industrial development was formed by the establishment on the banks of the Wupper of a number of bleachers, who obtained a monopoly in 1532. Municipal rights were granted in 1610, a great increase of the manufactures effected in the beginning of the 18th century, silk-weaving introduced in 1760, and the dyeing of Turkey red commenced in 1780.

See Coustelle, *Elberfeld, topographisch-statistische Darstellung*, Elberfeld, 1853. Langewiesche, *Elberfeld und Barmen*, Barmen, 1863.

ELBEUF, a town of France in the department of Seine Inférieure, 13 miles S. of Rouen, on the left bank of the Seine, with a station on the railway between Oissel and Serquigny. It has three parish churches, a Protestant place of worship, a town-house with a natural history museum, a public library, a hospital, an industrial society, an archaeological society, and a chamber of arts and sciences. The churches of St Étienne and St Jean are both of some antiquity, and preserve stained glass of the 15th and 16th centuries. The town is one of the principal seats of the woollen manufacture in France: more than half of the inhabitants are directly maintained by the staple industry, and numbers more by the auxiliary crafts. As a river-port it has a brisk trade in the produce of the surrounding district as well as in the raw materials of its manufactures. A suspension bridge communicates with St Aubin, and steam-boats ply regularly to Ronen. The population, which was only about 4600 in the end of last century, amounted in 1831 to 10,258, and in 1872 to 22,563. If the quasi-suburban towns of Candebeac-lès-Elbeuf, Saint-Pierre-lès-Elbeuf, and St Aubin-jouxte-Boulleng be included, this great industrial congeries will comprise upwards of 39,000 inhabitants.

Elbeuf is an old town, and the site was probably occupied during the Roman period. In the 14th century it was made a countship, and in 1554 it passed by marriage to Duke René of Lorraine. By King Henry III it was raised to the rank of a duchy in favour of Charles, grandson of Claude of Lorraine, but the dukes of Elbeuf made no figure in history, and in 1763 the title passed to the house of Harcourt. The town and its industries were greatly patronized by Colbert, but the revocation of the Edict of Nantes soon after neutralized the beneficial effects of his regulations, and it was not till 1814 that the removal of Belgian competition gave the new impetus which is still at work. In that year there were 80 factories producing goods to the value of 25 millions of francs, in 1840 the factories numbered 200, and the value of the goods amounted to 40 or 45 millions.

ELBING, a seaport town of Prussia, at the head of a circle in the government of Dantzg, 36 miles E.S.E. of the city of that name, on the Elbing, a small river which flows into the Frische Haff about four miles from the town, and is united with the Nogat or eastern arm of the Vistula by means of the Kraffohl canal. The old town was formerly surrounded by fortifications, but of these only a few fragments remain. There are seven Evangelical, one Roman Catholic, and two Mennonite churches, a synagogue, a gymnasium founded in 1536, with a public library of

22,000 volumes, an orphan-asylum, several hospitals, and numerous charitable institutions. Of these last a number owe their existence to the bequests of an Englishman, Richard Cowle, who settled in the town in 1810 and died at Dantzic in 1821. The manufacturing industry is extensive and varied, producing, among the rest, iron goods, iron ships, and machinery, sail-cloth, woollen cloth, leather, paper, tobacco, starch, vitriol, and vinegar; and the transit trade has received a considerable increase by the opening of the Overland canal (1846–1861).

The existence of Elbing is due to a colony of Lübeck traders who settled under the protection of the castle of the Teutonic Knights in 1237. Invested with the Lübeck rights, and afterwards admitted into the Hanseatic confederation, the settlement was highly prosperous, and in 1335 greatly extended its limits by laying out a New Town. In 1434 it paid allegiance to Poland, and in 1454 was made the seat of a *waivode*; but in 1525 it was captured by Albert of Brandenburg, Grand Master of the Teutonic Order. After various vicissitudes, it came at last to Prussia in 1772—decadent and declining; and its present prosperity is of quite recent date. Population in 1875, 33,572.

ELCHE, a town of Spain, in the province of Alicante, six miles from the sea, on the river Vinalopo. It has three churches, as many monastic buildings, a hospital, barracks, and an old episcopal palace; but there is nothing of architectural interest except perhaps the portico of Santa Maria. The costume and physiognomy of the inhabitants, the narrow streets and flat-roofed white-washed houses, and more than all the thousands of palm-trees in its gardens and fields, gave the place a strikingly Oriental aspect, and render it unique among the cities of Spain. The cultivation of the palm is indeed the principal occupation; and though the dates are inferior to those of Barbary, the annual value of the crop is about £14,000. The blanched fronds are also sold in large quantities for the processions of Palm-Sunday; and after they have received the blessing of the priest, they are regarded throughout Spain as certain defences against lightning.

Elche is identified with the ancient *Ilici* or *Illici* of the Contestani, which under the Romans obtained the rank of a colony with the *jus italicum*. In 1392 it was attacked by the Moors of Granada, who discharged against it "iron balls through fire." Population 18,734.

ELDAD BEN MALCHI, also surnamed Ha-Dani, Abu-Dani, Daud-Ha-Dani, or the Danite, a Jewish traveller of the 9th century of the Christian era, chiefly interesting on account of the light (or darkness) which his writings throw on the question of the Lost Tribes. The date and place of his birth are not accurately known; but he was a native either of South Arabia or of Media. About 860 he set out with a companion to visit his Jewish brethren in Africa and Asia. Their vessel was wrecked, and they fell into the hands of cannibals; but Eldad was saved from the inhuman fate of his comrade, first by his leanness and afterwards by the opportune invasion of a neighbouring tribe. He spent four years with his new captors, was ransomed by a fellow-countryman, continued his journey as far, according to one interpretation of his story, as China, spent several years at Kairwan in Tunis, and died on a visit to Cordova in Spain. The work which goes under his name is written in Hebrew, and consists of six chapters, probably abbreviated from the original form of the narrative. It was first printed at Constantinople in 1518; and the same recension afterwards appeared at Venice in 1540 and 1605, and at Jessnitz in 1722. A Latin version by Genebrard was published at Paris in 1563, under the title of *Eldad Danius de Judæis clausis eorumque in Æthiopia imperio*, and was afterwards incorporated in the translator's *Chronographia Hebræorum*; a German version appeared at Prague in 1695, and another at Jessnitz in 1723. In 1838 M. Carmoly edited and translated a fuller recension which he had found in a MS. from the library of Eliezer Ben Hasan, forwarded to him

by Daud Zabach of Morocco. Both forms are printed by Dr Jellinek in his *Beth-Ha-Midrash*, vols. ii. and iii., Leipsic, 1853–55. One of the most curious passages in the work is the account of the Levites, who, says the author, were miraculously guided to the land of Havila, and are there protected from their enemies by the mystic river Sabbath, which on the Sabbath is calm and involved in delusive mists, and on the other days of the week runs with a fierce and fordless current.

See Bartolucci, *Bibliotheca Magna Rabbinnica*, vol. i.; Fürst, *Bibliotheca Judaica*; Grätz, *Geschichte der Juden*, vol. v.; Rossi, *Dizionario degli Ebrei*, and Kitto's *Biblical Cyclopædia*, 3d edition, *sub nomine*.

ELDER, the name of an office both in the Jewish and in the Christian church, which is used in modern times only by Presbyterians. As first applied, among the ancient Jews, for example, it had no doubt a literal fitness, indicating the responsibility and authority that naturally accrue in any community to those advanced in age. As the office gradually came to be fixed in its character and limited in the number of its occupants, the name lost something of its literal fitness, the responsibility and authority becoming attached to it without regard to the age of the occupant. In this respect the kindred terms *alderman*, *senator*, &c., have had a similar history. In the Old Testament usage of the word it is impossible to fix any exact point of time at which it passed from its primary or etymological to its secondary or official sense, as the process was a gradual one, and old age continued to be a leading qualification for the office long after it had ceased to be essential. In Exodus iii. 16 elders are mentioned as a recognized official body among the Israelites, and in subsequent notices (Ex. xix. 7; Ex. xxiv. 1, Deut. xxxi. 9) they appear as the representatives of the whole body of the people. In Numbers xi. 16, 17, seventy elders, to be chosen out of the entire body, were set apart "to bear the burden of the people" along with Moses. It is unnecessary to enter here into any discussion of the moot question of the connection of this Mosaic council of seventy with large though undefined legislative and executive powers with the Sanhedrin as it existed at the time of Christ. From the time of the institution of the Mosaic council the elders are mentioned at each successive stage of Jewish history. After the settlement in Canaan they acted as the administrators of the laws in every city (Deut. xix. 11–12; xxi. 3–9, 19; xxii. 15–21); and references to them are frequent during the period of the judges and the kings, during the captivity, and after the restoration. In the New Testament the word is used to denote both an order of the Jewish economy and an office of the Christian church. Its precise significance in the latter usage is the main subject in the standing controversy between Episcopalians and Presbyterians, and a statement of the arguments on either side belongs properly to the articles on Episcopacy and Presbytery respectively. Reference must also be made to the article on Presbytery for a full statement of the qualifications, duties, and powers of elders in a presbyterian church. It may be noted here that while the New Testament word *presbyteros* denotes, according to the admission of the adherents of all forms of church government, those especially set apart to the pastoral office, whatever else it may be held to include, its English equivalent *elder* is used as an official designation only in the presbyterian church. According to the presbyterian theory of church government there are two classes of elders, *teaching* elders, or those set apart specially to the pastoral office, and *ruling* elders, who are laymen, chosen generally by the congregation, and set apart by ordination to be associated with the pastor in the oversight and government of the church. When the word is used without any qualification, it is understood to apply to the latter class alone.

ELDER (Ang.-Sax. *ellarn*; Ger. *Holunder*; Fr. *sureau*), the popular designation of the deciduous shrubs and trees constituting the genus *Sambucus* of the natural order *Caprifoliaceæ*. The Black-berried or Common Elder, *S. nigra*, the bountree of Scotland, is found in Europe, the north of Africa, Western Asia, the Caucasus, and Southern Siberia, in sheltered spots it attains a height of over 20 feet. The bark is smooth, the shoots are stout and angular, and the leaves glabrous, pinnate, and generally oval or elliptical. The flowers, which form corymbose cymes, with five main branches, have a cream-coloured, gamopetalous, five-lobed corolla, five stamens, and three sessile stigmas; the berries are purplish-black, globular, and three- or four-seeded, and ripen about September. The elder thrives best in moist, well-drained situations, but can be grown in a great diversity of soils. It is propagated by young shoots, which after a year are fit for transplantation. It is found useful for making screen-fences in bleak, exposed situations, and also as a shelter for other shrubs in the outskirts of plantations. By clipping two or three times a year, it may be made close and compact in growth. The young trees furnish a brittle wood, containing much pith; the wood of old trees is white, hard, and close-grained, and polishes well, and is employed for shoemakers' pegs, combs, skewers, mathematical instruments, and turned articles. Young elder twigs deprived of pith have from very early times been in request for making whistles, popguns, and other toys.

The elder was known to the ancients for its medicinal properties, and in England the inner bark was formerly administered as a cathartic. The flowers (*sambucus flores*) contain a volatile oil, and are reputed to be diaphoretic in properties, they serve for the preparation of an ointment (*unguentum sambuci*), and for the distillation of elder-flower water (*aqua sambuci*), used in confectionery, perfumes, and lotions. The leaves of the elder are employed to impart a green colour to fat and oil (*unguentum sambuci foliorum* and *oleum viride*), and the berries for making wine, a common adulterant of port. The leaves and bark emit a sickly odour, believed to be repugnant to insects. Christopher Gullet (*Phil. Trans.*, 1772, lxi. p. 348) recommends that cabbages, turnips, wheat, and fruit trees, to preserve them from caterpillars, flies, and blight, should be whipped with twigs of young elder. According to German folk-lore, the hat must be doffed in the presence of the elder-tree, and in certain of the English midland counties a belief was once prevalent that the cross of Christ was made from its wood, which should therefore never be used as fuel, or treated with disrespect (see *Quart. Rev.*, cxiv. 233). It was, however, a common mediæval tradition, alluded to by Ben Jonson, Shakespeare, and other writers, that the elder was the tree on which Judas hanged himself; and on this account, probably, to be crowned with elder was in olden times accounted a disgrace. In *Cymbeline* (act iv. s. 2) "the stinking elder" is mentioned as a symbol of grief. In Denmark the tree is supposed by the ensuperstious to be under the protection of the "Elder-mother" its flowers may not be gathered without her leave, its wood must not be employed for any household furniture, and a child sleeping in an elder-wood cradle would certainly be strangled by the Elder-mother.

S. nigra virens is a variety of *S. nigra* having white bark and green-coloured berries, some ornamental varieties have blotched leaves. The Scarlet-berried Elder, *S. racemosa*, is the handsomest species of its genus. It is a native of various parts of Europe, growing in Britain to a height of over 15 feet, but often producing no fruit. The Dwarf Elder or Danowort, *S. Ebulus*, a common European species, reaches a height of about 6 feet. Its cyme is hairy, has three principal branches, and is smaller than that of *S. nigra*, the flowers are of a dull purplish hue. All parts of the plant are cathartic and emetic.

ELDON, JOHN SCOTT, BARON, and afterwards **EARL OF** (1751–1838), lord high chancellor of England, was born at Newcastle on the 4th June 1751. His grandfather, William Scott, of Sandgate, a suburb of Newcastle, was clerk to a "fitter"—a sort of water-carrier and broker of coals. His father, whose name also was William, began life as an apprentice to a fitter, in which service he obtained the freedom of Newcastle, becoming a member of the guild of Hostmen, later in life he became a principal in the business, and attained a respectable position as a merchant in

Newcastle, accumulating property worth nearly £20,000. He was twice married; his second wife, the mother of John Scott, says Lord Campbell (*Lord Chancellors*, vol. vii. p. 4), "was a woman of such superior understanding, that to her is traced the extraordinary talent which distinguished her two sons, William and John—Lord Stowell and Lord Eldon." It may be mentioned that William and John had each of them a twin sister.

The boys were educated at the grammar school of their native town, where, however, they scarcely gave promise of the splendid careers which they were destined to run. John Scott was not remarkable at school for application to his studies, though his wonderful memory enabled him to make good progress in them; he frequently played truant, and was whipped for it, robbed orchards, and indulged in other questionable school-boy freaks, nor did he always come out of his scrapes with honour and a character for truthfulness. When John had finished his education at the grammar school, his father thought of apprenticing him to his own business, to which an elder brother Henry had already devoted himself, and it was only through the interference of William, who had already obtained a fellowship at University College, Oxford, that it was ultimately resolved that he should continue the prosecution of his studies. Accordingly, on the 15th May 1766, John Scott entered University College as a commoner, with the view of entering the church, and obtaining a college living. In the year following he obtained a fellowship, graduated B.A. in 1770, and in 1771 won the prize for the English essay, the only university prize open in his time for general competition. It does not appear, however, that he distinguished himself at college any more than he had done at school by any severe application to study. It was not till after his marriage that he first concentrated his energies on the congenial study of law.

His wife was the eldest daughter of Mr Aubone Surtees, a Newcastle banker. John Scott first met her at Sedgefield Church, in the county of Durham, and a strong attachment sprang up between them. The Surtees family objected to the match, and attempted to prevent it; but the fire once kindled was not to be put out. On the 18th November 1772, Scott, with the aid of a ladder and an old friend, carried off the lady from her father's house in the Sandhill, across the border to Blackshields, in Scotland, where they were married. The father of the bridegroom objected not to his son's choice, but to the time he chose to marry; for it was a blight on his son's prospects, depriving him of his fellowship and his chance of church preferment. But while the bride's family refused to hold intercourse with the pair, Mr Scott, like a prudent man and an affectionate father, set himself to make the best of a bad matter, and received them kindly, settling on his son £2000. John returned with his wife to Oxford, and continued to hold his fellowship for what is called the year of grace given after marriage, and added to his income by acting as a private tutor. After a time Mr Surtees was reconciled with his daughter, and made a liberal settlement on her. John Scott's year of grace closed without any college living falling vacant; and with his fellowship he gave up the church, and turned to the study of law. He became a student at the Middle Temple in January 1773, and in February took his degree of M.A. at Oxford. In 1776 he was called to the bar, intending at first to establish himself as an advocate in his native town, a scheme which his early success led him to abandon, and he soon settled to the practice of his profession in London, and on the Northern Circuit. Thus, at last, had he started on the high road to the chancellorship, having narrowly escaped becoming a coal-fitter, a country parson, a provincial barrister, and, according to one account, a retailer of figs and raisins.

In the autumn of the year in which he was called to the bar his father died, leaving him a legacy of £1000 over and above the £2000 previously settled on him. He was already an excellent lawyer, and succeeded fairly well on his first circuit, though not so well as to satisfy him of the safety of attempting a London career. He therefore took a house in Newcastle, with the view of establishing himself there, but still delayed to leave London; and his prospects there suddenly improving, he assigned the Newcastle house to his brother Henry. In his second year at the bar his prospects began to brighten. His brother William, who by this time held the Camden professorship of ancient history, and enjoyed an extensive acquaintance with men of eminence in London, was in a position materially to advance his interests. Among his friends was the notorious Bowes of Gbyside, to the patronage of whose house the rise of the Scott family was largely owing. Bowes having contested Newcastle and lost it, presented an election petition against the return of his opponent. Young Scott was retained as junior counsel in the case, and though he lost the petition he did not fail to improve the opportunity which it afforded for displaying his talents. This engagement, in the commencement of his second year at the bar, and the dropping in of occasional fees, must have raised his hopes; and he now abandoned the scheme of becoming a provincial barrister. A year or two of dull drudgery and few fees followed, and he began to be much depressed. But in 1780 we find his prospects suddenly improved, by his appearance in the case of *Ackroyd v. Smithson*, which became a leading case settling a rule of law; and young Scott, having lost his point in the inferior court, insisted on arguing it, on appeal, against the opinion of his clients, and carried it before Lord Thurlow, whose favourable consideration he won by his able argument. The same year Bowes again retained him in an election petition, and in the year following Scott greatly increased his reputation by his appearance as leading counsel in the Clitheroo election petition. From this time his success was certain. In two years he obtained a silk gown, and was so far cured of his early modesty that he declined accepting the king's counselship if precedence over him were given to his junior, Mr Erskine, though the latter was the son of a peer and a most accomplished orator. He was now on the high way to fortune. His health, which had hitherto been but indifferent, strengthened with the demands made upon it; his talents, his power of endurance, and his ambition all expanded together. He enjoyed a considerable practice in the northern part of his circuit, before parliamentary committees, and at the Chancery bar, and was in sight of the honours and emoluments of the solicitor and attorney generalships. By 1787 his practice at the Equity bar had so far increased that he was obliged to give up the eastern half of his circuit (which embraced six counties), and attend it only at Lancaster.

Shortly after taking the silk gown, he entered Parliament for Lord Weymouth's close borough of Weobley, which Lord Thurlow obtained for him without solicitation. In Parliament he gave a general and independent support to Pitt. His first parliamentary speeches were directed against Fox's India Bill. They were unsuccessful. In one he aimed at being brilliant; and becoming merely laboured and pedantic, he was covered with ridicule by Sheridan, from whom he received a lesson which he did not fail to turn to account. In 1788 Pitt conferred upon him the honour of knighthood and the office of solicitor-general; and at the close of this year he attracted attention by his speeches in support of Pitt's resolutions on the state of the king (George III., who then laboured under a mental malady) and the delegation of his authority. It is said that he drew the Regency Bill, which was introduced

in 1789. In 1793 Sir John Scott was promoted to the office of attorney-general, in which it fell to him to conduct the memorable prosecutions for high treason against British sympathizers with French republicanism,—amongst others, against the celebrated Horne Tooke. These prosecutions, in most cases, were no doubt instigated by Sir John Scott, and were the most important proceedings in which he was ever professionally engaged. He has left on record, in his *Anecdote Book*, a defence of his conduct in regard to them. A full account of the principal trials, and of the various legislative measures for repressing the expressions of popular opinion for which he was more or less responsible, will be found in Twiss's *Public and Private Life of the Lord Chancellor Eldon*, and in the *Lives of the Lord Chancellors*, by Lord Campbell. In 1799 the office of chief-justice of the Court of Common Pleas falling vacant, Sir John Scott's claim to it was not overlooked; and after seventeen years' service in the Lower House, he entered the House of Peers as Baron Eldon. In February 1801, the ministry of Pitt was succeeded by that of Addington, and the chief-justice now ascended the woolsack. The chancellorship was given to him professedly on account of his notorious anti-Catholic zeal. From the Peace of Amiens (1801) till 1804, Lord Eldon appears to have interfered little in politics. In the latter year we find him conducting the negotiations which resulted in the dismissal of Addington and the recall of Pitt to office as prime minister. Lord Eldon was continued in office as chancellor under Pitt, but the new administration was of short duration, for on the 23d of January 1806 Pitt died, worn out with the anxieties of office, and his ministry was succeeded by a coalition, under Lord Grenville. The death of Fox, who became foreign secretary and leader of the House of Commons, soon, however, broke up the Grenville administration; and in the spring of 1807, Lord Eldon once more, under Lord Liverpool's administration, returned to the woolsack, which, from that time, he continued to occupy for about twenty years, swaying the Cabinet, and being in all but name prime minister of England. It was not till April 1827, when the premiership, vacant through the paralysis of Lord Liverpool, fell to Mr Canning, the chief advocate of Roman Catholic emancipation, that Lord Eldon, in the seventy-sixth year of his age, finally resigned the chancellorship. When, after the two short administrations of Canning and Goderich, it fell to the duke of Wellington to construct a Cabinet, Lord Eldon expected to be included, if not as chancellor, at least in some important office, but he was overlooked, at which he was much chagrined. Notwithstanding his frequent protests that he did not covet power, but longed for retirement, we find him again, so late as 1835, within three years of his death, in hopes of office under Peel. He spoke in Parliament for the last time in July 1834.

In 1821 Lord Eldon had been created earl by George IV., whom he managed to conciliate, partly, no doubt, by espousing his cause against his wife, whose advocate he had formerly been, and partly through his reputation for zeal against the Roman Catholics. In the same year, his brother William, who from 1798 had filled the office of judge of the High Court of Admiralty, was raised to the peerage under the title of Lord Stowell.

Lord Eldon's wife, his dear "Bessy," his love for whom is a beautiful feature in his life, died before him, on the 28th June 1831. By nature she was of simple character, and by habits acquired during the early portion of her husband's career almost a recluse. Two of their sons reached maturity,—John, who died in 1805, and William Henry John, who died unmarried in 1832. Lord Eldon himself survived almost all his immediate relations. His brother William died in 1836. He him

self died, in London, in his eighty-seventh year, on the 13th January 1838, leaving behind him two daughters, Lady Frances Bankes and Lady Elizabeth Repton, and his grandson, who succeeded him. "When his remains lay in state in Hamilton Place," says Lord Campbell, "large numbers of all classes went to see the solemn scene, and when the funeral procession, attended by the carriages of the princes of the blood, many members of the peerage, and all the dignitaries of the law, blackened the way, dense crowds stood uncovered, respectfully gazing at it as it passed." His remains were interred in the family vault in the chapel of Kingston, in Dorsetshire. The fortune which he left behind him exceeded in amount half a million of money.

Lord Eldon was no legislator,—his one aim in politics was to keep in office, and maintain things as he found them, and almost the only laws he helped to pass were laws for popular coercion. For nearly forty years he fought against every improvement in law, or in the constitution,—calling God to witness, on the smallest proposal of reform, that he foresaw from it the downfall of his country. Without any political principles, properly so called, and without interest in or knowledge of foreign affairs, he maintained himself and his party in power for an unprecedented period by his great tact, and in virtue of his two great political properties—of zeal against every species of reform, and zeal against the Roman Catholics. To pass from his political to his judicial character is to shift to ground on which his greatness is universally acknowledged. His judgments, which have received as much praise for their accuracy as abuse for their clumsiness and uncouthness, fill a small library. But though intimately acquainted with every nook and cranny of the English law, he never carried his studies into foreign fields, from which to enrich our legal literature; and it must be added that against the excellence of his judgments, in too many cases, must be set off the hardships, worse than injustice, that arose from his protracted delays in pronouncing them. A consummate judge and the narrowest of politicians, he was Doubt on the bench and Promptness itself in the political arena. For literature, as for art, he had no feeling. What intervals of leisure he enjoyed from the cares of office he filled up with newspapers and the gossip of old cronies. Nor were his intimate associates men of refinement and taste, they were rather good fellows who quietly enjoyed a good bottle and a joke, he uniformly avoided encounters of wit with his equals. He is said to have been parsimonious, and certainly he was quicker to receive than to reciprocate hospitalities; but his mean establishment and mode of life are explained by the retired habits of his wife, and her dislike of company. His manners were very winning and courtly, and in the circle of his immediate relatives he is said to have always been lovable and beloved. "He is one," says Miss Martineau, "that after times will not venerate, but fortunately for the fame of the larger num-

ber of the great ones of the earth, there is a vast neutral ground between veneration and contempt."

"In his person," says Lord Campbell, "Lord Eldon was about the middle size, his figure light and athletic, his features regular and handsome, his eye bright and full, his smile remarkably benevolent, and his whole appearance prepossessing. The advance of years rather increased than detracted from these personal advantages. As he sat on the judgment-seat, 'the deep thought betrayed in his furrowed brow,—the large eyebrows, overhanging eyes that seemed to regard more what was taking place within than around him,—his calmness, that would have assumed a character of sternness but for its perfect placidity,—his dignity, repose, and venerable age, tended at once to win confidence and to inspire respect' (Townsend). He had a voice both sweet and deep-toned, and its effect was not injured by his Northumbrian burr, which, though strong, was entirely free from harshness and vulgarity."

EL DORADO, that is, in Spanish, "The Golden," a mythical country long believed to exist in the northern part of South America. The origin of the legend has been variously explained, some supposing that the micaceous quartz in the valley of the Essequibo was mistaken for gold ore, while others find the nucleus of the story in the fact that the high-priest of Bogotá was accustomed to sprinkle himself with gold dust, which was afterwards washed off in a neighbouring lake. It hardly seems necessary, however, to accept either or indeed any theory of explanation: the minds of the Spanish explorers had been dazzled by the wealth of their earlier conquests, and the most brilliant imagination seemed to have a possibility of fulfilment. Martinez, a Spaniard, who had been set adrift on the sea, asserted that he was flung on the coast of Guiana, and conducted inland to a city called Manoa, which was governed by a king in alliance with the Incas, and lavished the precious metals on its roofs and walls. Orellana, who passed down the Rio Napo to the valley of the Amazon in 1540, also brought back an account of a land of fabulous wealth; and Philip von Hutten, who led an exploring party from Coro, on the coast of Caracas, during the period from 1541 to 1545, believed he had caught sight of the golden splendours of the city of his search. In spite of the failure of expedition after expedition, and notably of that undertaken in 1569 by Gonzalo Ximenez de Quesada from Santa Fé de Bogotá, the fable continued a potent allurements for adventurous spirits, and even in the beginning of the 17th century exerted a master-influence on the schemes of Sir Walter Raleigh. Traces of the pseudo-discoveries of Martinez and his compeers disfigured our maps till the time of Humboldt, who proved that the great lake of Parima to the east of Manoa was almost as fabulous as the city itself; and the name of El Dorado remains a permanent gain to our metaphorical vocabulary. Allusions more or less direct to the legend abound in European literatures, one of the most detailed being the well-known chapter in Voltaire's *Candide*.
